Test calves were isolated at birth in disinfected cement stalls with fresh oat straw for bedding. For the first 3 days they had colostrum and then whole milk. Hay was offered from the fourth day and after a week 500 g. calf meal also. Four calves were not inoculated ; 4 were inoculated daily from the 4th to the 18th day with commercial preparations, A or B, and 2 on the 4th and 5th day with a fresh bolus of cud. As soon as hay was eaten, samples of rumen contents were taken regularly by stomach tube. The samples were filtered under CO_2 at 39° C., the cellulose-splitting activity was estimated in an artificial rumen, and bacterial counts were made.

The results show that drying produced considerable changes in the micro-organisms, both commercial preparations showing an excess of less desirable forms, such as spore-forming anaerobes

and *Bacterium coli*; characteristic rumen organisms were not found. Clinically the dried preparations did no good; in particular, they did not prevent diarrhoea. The calves given cud developed a normal rumen flora within 2 weeks and there was no diarrhoea.—I. Leitch.

WILSON, M. K. and BRIGGS, C. A. E. **The normal flora of the bovine rumen. 2. Quantitative bacteriological studies.** *J. Appl. Bacteriol.*, 1955, **18**, 294–306. [Nat. Inst. Res. Dairying, Univ. Reading.]

For part 1 see Abst. 5015, Vol. 24.

2. Counts of viable bacteria from cows with rumen fistulae were made as described in part 1. Figures for numbers viable are given for 5 portions of the rumen, for day-to-day variations from 1 animal, for different cows on the same diet, for different rations, and for hourly samples from individual cows during 25-hr. and 7-hr. periods.

Numbers viable under these conditions ranged from 10^7 to 10^{12} per g., with 94 per cent. of counts between 10^8 and 10^{10} per g. A high correlation was found between these counts and direct microscope counts made by mixing suitable dilutions of rumen fluid with nigrosine and spreading a known volume over 4 sq. cm. on a slide.—J. C. Appleby.

BENTLEY, O. G., JOHNSON, R. R., HERSHBERGER, T. V., CLINE, J. H. and MOXON, A. L. **Cellulolytic-factor activity of certain short-chain fatty acids for rumen microorganisms *in vitro*.** *J. Nutrition*, 1955, **57**, 389–400. [Dept. Animal Sci., Ohio Agric. Exp. Stat., Wooster.]

Rumen fluid obtained from steers fed on alfalfa hay was passed through a Sharples centrifuge and the deposit of microflora and other suspended material was collected. The deposit from 1 litre of fluid was suspended in 200 ml. phosphate buffer at *p*H 7 containing 0·01 per cent. cysteine hydrochloride. This suspension was added to a medium containing 1·0 g. cellulose, 0·168 g. urea, 0·1 g. glucose, salts, *p*-aminobenzoic acid and biotin. CO_2 was passed through the mixture and the *p*H was maintained at 6·7 to 6·9 by adding saturated Na_2CO_3 solution. After fermentation for 30 hr. the volume was adjusted to 100 ml. and the disappearance of cellulose was estimated on duplicate 10-ml. aliquots.

The addition of 10 ml. rumen fluid or the steam distillate from 20 ml. rumen fluid to the basal medium increased the rate of digestion of cellulose about threefold. Short-chain fatty acids were then added to the basal medium at the rate of 2 to 10 mg. per 100 ml. and it was found that valeric and caproic acids and, to a less extent, *iso*butyric and *iso*valeric acids increased the rate of breakdown of cellulose. The activity of the volatile fatty acid fraction of rumen fluid was found to be mainly due to valeric acid.—G. A. Garton.

NESENI, R. and MÜLLER, C. Über die Muskelfaserstärke von Klein- und Grosstieren. [**Strength of the muscle fibres of small and large animals.**] *Ztschr. Tierzücht. Züchtungsbiol.*, 1955, **65,** 335–358. [Inst. Tierzuchtforsch., Dummerstorf.]

The muscle fibres of geese, cocks, rabbits, wethers, pigs and cattle were compared. There were differences with age and bodyweight and possibly with sex. There was no difference due to diet in cocks, and the difference between 3 groups of geese on different diets may have been due to age, not diet. Wethers kept entirely indoors had less strong muscle fibres than those which spent part of their time on pasture.—D. Duncan.

3497

SERGEEVA, M. A. Vliyanie pitaniya s razlichnym sootnosheniem zhirov i uglevodov na uslovnoreflektornuyu deyatelnost sobak. [**The influence of different ratios of fat and carbohydrate in the diet on conditioned reflex activity in the dog.**] *Vop. Pitan.*, 1956, **15,** 9–15. [Inst. Pitan., Akad. Med. Nauk SSSR, Moscow.]

In 4 dogs with the conditioned reflex of salivation in response to different stimuli, the responses were less and the latent period was longer when the diet contained 60 per cent. fat and 20 per cent. carbohydrate than on the isocaloric standard diet with 30 and 50 per cent., respectively. Excitability was increased when the diet contained 15 per cent. fat and 65 per cent. carbohydrate.—D. Duncan.

HELLSTRÖM, B. E. **Experimental approach to the pathogenesis of retrolental fibroplasia. 5. The influence of the state of nutrition on oxygen-induced changes in the mouse eye.** *Acta paediat.*, 1956, **45,** 43–57. [Histol. Dept., Karolinska Inst., Stockholm.] French, German and Spanish summaries.

[Early papers in the series had no bearing on nutrition.]

5. Groups of mice, 16 hr. old, were exposed for 10 days to oxygen concentrations of 98 to 100 per cent. Some groups were then killed, others were kept for a further 10 days in air. Some groups were underfed or overfed during exposure to oxygen, and were fed normally during subsequent stay in air; some were overfed or underfed for both periods, others were fed normally throughout. One group was underfed without exposure to oxygen and a final group was exposed neither to oxygen nor to under- or over-feeding. Underfeeding was effected by separating the young from their mothers every third day and by increasing the number of young given to one mother to nurse. Overfeeding was effected by reducing the number nursed by one mother. Underfeeding reduced rate of weight gain to about half that of controls. There was slight retardation of the outgrowth of vessels in the retina, other signs of delayed differentiation of the eye and frequent haemorrhages in the nerve fibre layer. Oxygen exposure caused a complete, or almost complete, inhibition of outgrowth of retinal vessels, irrespective of the state of nutrition.

The hyperplasia of vessels of the nerve fibre layer, which occurs when animals exposed to oxygen are transferred to air, was greater in those underfed during exposure to oxygen than in those overfed during exposure to oxygen, and was greater in the latter than in animals underfed both during exposure to oxygen and during subsequent stay in air. The proliferation of hyaloid vessels was not influenced by nutrition. The findings are discussed in relation to retrolental fibroplasia in premature infants.—F. C. Aitken.

BIELIŃSKA, Z. Badania biologiczne nad wartością odżywcza wytypowanej, ograniczonej racji pokarmowej dla człowieka. [**Biological studies on the nutritive value of prescribed limited food ration for man.**] *Rocz. Państwowego Zakł. Hig.*, 1955, **6,** 401–417. Russian and English summaries.

The object of this study was to assess the effects which a deficient diet would have on man by studying its effects on rats. The diet would provide for a human subject 2550 Cal., protein 73 g., fat 51 g., carbohydrate 450 g., Ca 0·7 g., Fe 23 mg., vitamin B_1 2 mg., riboflavin 1·9 mg., vitamin C 73 mg. and carotene 6700 I.U. This diet was adapted for rats; in comparison with the stock diet, an isocaloric supply of this diet was low in protein, 9·5 against 25·4 per cent., in Ca, 115 against 1479·5 mg. per cent., in P, 243 against 964·5 mg. per cent. and in Fe, 9·8 against 40·2 mg. per cent.

The effect of the diet on growth and reproduction of 15 rats about 4 weeks old was studied first. Ten similar rats on the stock diet served as controls. After 5 months the bodyweight of the experimental animals was about half that of controls, and they had lighter build and scanty, dry hair with impaired pigmentation. Most of them had conjunctivitis. The average litter size in the experimental group, among those females which were mated successfully, was 4, that of controls 8. Three out of 10 females and one out of 5 males were infertile.

Apart from conjunctivitis the animals were generally free of disease ; but among those females who had had young there occurred vertigo caused by abscess of the middle ear, deep abscess in the upper part of the sternum, changes in the respiratory system, and cracking of skin with ecchymosis on the back, just below the neck. Females which did not reproduce were more lively and did not show any pathological change either when alive or at post mortem. X-ray photographs showed considerable decalcification of bones, least among non-reproducing females, greater among those which reproduced but did not lactate, and greatest among those which lactated.

The diet produced a much less spectacular effect on rats 2½ months old, but weight gain was significantly impaired. In the next experiment 4 male and 8 female rats were kept for 3½ months on the stock diet and were then switched to the experimental diet for 1 month before mating and during pregnancy and lactation. Their reproductive capacity did not appear to be affected. After giving birth the females appeared normal and fed their young, but in one changes of reproductive organs and enlargement of the spleen were found at post mortem. X-ray films showed some decalcification of bones, but no deformity.

The second generation of experimental rats, kept on the deficient diet, showed very poor growth. Second-generation animals aged 5 months weighed only 39 per cent. of the normal and were considerably shorter than their parents, which in turn were significantly shorter than control rats ; the average lengths were 25·7, 32·3 and 35 cm. in the above order. The second generation was characterised by poor condition, light build, poor hair and relatively large head. There were also some developmental changes, especially in the eyes, which were protuberant in some and had unusually small eye-balls in others ; the experimental rats were also prone to infection, especially of the respiratory system. Bony structure and teeth were grossly deformed. Bones were brittle and deformities of vertebral column, ribs and legs were found. Attempts to obtain a third generation of experimental rats were unsuccessful.

BARTNIK, J., PIEKARSKA, J. and KLIMCZAK, Z. Wpływ naturalnych produktów spożywczych na wartość odżywczą i biologiczne działanie pożywienia. [**The effect of natural foods on the nutritive and biological value of the diet.**] *Rocz. Państwowego Zakł. Hig.*, 1955, **6,** 389–399. Russian and English summaries.

Rats 3 weeks old and weighing on the average 53 g. were divided into 3 groups of 12, 6 males and 6 females in each. Each group was kept on a diet composed of different proportions of potatoes, sauerkraut, beans, coarse rye flour, casein, lard and sugar. Vegetable products made up 80, 50 and 33 per cent. of the rations. All diets were supplemented with vitamins and minerals in sufficient quantities. The diets were approximately isocaloric and of equal protein content. The experiment was divided into 5 days of adaptation and 3 experimental periods. In period 1, 59 days, all rats were kept on diets described above. In period 2, 20 days, all rats were given diet 1. In period 3, 20 days, all rats were given a stock diet.

Diets 1 and 2 were eaten willingly, but diet 3 appeared to be much less appetising. Diet 2 gave the best coefficients of food utilisation. The average weight gains per 100 Cal. digested of the 3 rations were 5·89, 5·97 and 5·33 g. The average gains per g. protein digested were 1·43, 1·54 and 1·35 g. The average daily weight gains in the 3 groups were 2·65, 2·58 and 2·25 g.

The results of the second and third periods suggest that the effects of malnutrition in the early stages of development of an animal are difficult or even impossible to correct later. It is considered that the results would be still more in favour of diets containing natural vegetable foods if they were given to appetite and without vitamin and mineral supplements.—W. Z. Billewicz.

RATNOFF, O. D., KOLETSKY, S. and PATEK, A. J. (Jr.) **Hepatic damage in rats fed human foodstuffs.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 620–623. [Dept. Med., Sch. Med., Western Reserve Univ., Cleveland, Ohio.]

Studies were made on young male rats which had received Purina dog chow and tap water to appetite until the start of the experiment. Twelve rats then continued to receive chow and water, 45 rats were given a diet of spaghetti, olive oil, and wine diluted with an equal volume of water, 12 rats a diet of spaghetti, olive oil and 10 per cent. glucose in water and 12 rats a diet of spaghetti, olive oil and diluted wine with a supplement of vitamins of the B group. All the diets were given to appetite and the foods used were analysed ; details of the composition of each food are given. Animals which survived were killed after from 45 to 343 days ; the livers of those and of animals which died or were killed when moribund were removed for examination.

The 12 animals fed on chow grew rapidly and remained healthy throughout the experiment ; histological examination of the liver revealed no abnormality. Significant liver lesions consisting of diffuse parenchymal necrosis and fatty infiltration occurred in the rats on the spaghetti diets. Both lesions were associated with moderate fibrosis ; the relative frequency of the lesion

depended on the nature of the diet and the duration of survival. The specific substances responsible for the changes were not ascertained.

HEWES, C. G. **The influence on the growth and progeny of the guinea pig resulting from oral administration of aureomycin (chlortetracycline) and penicillin.** *J. Nutrition*, 1955, **57**, 353–360. [Dept. Anat., Dent. Sch., Univ. Maryland, Baltimore.]

In a first experiment 3 groups, each of 12 male and 12 female 6-week-old guineapigs, were used. One group served as control and the other 2 groups received an aqueous solution of 0·55 mg. aureomycin or penicillin by mouth daily for one week and on alternate days for the remainder of the experiment. After 9 weeks 7 females from each group were mated with males of the same group. The offspring of each experimental animal were given 0·1 mg. of the antibiotic in aqueous solution by mouth daily for 6 weeks. The control animals were given a diet of rabbit chow with ascorbic acid added to their drinking water throughout the experiment.

In a second experiment 2 groups, each of 6 male weanling guineapigs, were given 0·3 and 0·5 mg. aureomycin by mouth, for 9 weeks. Growth and structural changes in tissues were compared with those of male controls in the first experiment.

The progeny of the animals treated with antibiotic had a slightly greater mean birthweight than the progeny of the control animals; this difference was no longer apparent after administration of the drugs to the young for 6 weeks. No other effect on reproduction was found. The guineapigs in the second experiment showed a significantly greater average weight than the controls after 9 weeks. Of the organs and tissues removed for study, only the tibiae of the experimental animals weighed significantly more than those of the controls. The heart and spleen weighed significantly less in the experimental animals than in the controls. Sections of these organs and tissues showed no histological difference between experimental and control animals. Increased structural growth was noted in the greater length of the tibia in the aureomycin-fed animals.—G. F. Garton.

SUR, G., SWAMINATHAN, M. and SUBRAHMANYAN, V. **Studies on the invitro digestibility of sago globules prepared from different starches by salivary and pancreatic amylases.** *Bull. Central Food Technol. Res. Inst., Mysore*, 1955, **5**, 1–2.

Sago globules prepared from raw starches of wheat, maize, rice, kaffir corn, milo, tapioca root, sweet potato, potato, arrowroot, banana stem and sago palm (*Metroxylon sago*) were used in digestibility studies *in vitro* with solutions of saliva and pancreatin. The digestibility of the raw starches and the cooked and uncooked sago globules was estimated.

Raw tapioca starch and cereal starches were digested equally well, the other starches less well. Sago cooked was better digested than uncooked, and uncooked sago better than raw starch.

YOSHIDA, M. and MORIMOTO, H. **Utilization of sweet potato starch by rats and its effect on the digestion of dietary protein.** *J. Nutrition*, 1955, **57**, 565–577. [Lab. Animal Feeding, Nat. Inst. Agric. Sci., Chiba-shi, Japan.]

In digestibility trials 8 male rats were given diets of starch 65, butterfat 10, casein 10, fishmeal 5, brewer's yeast 4, cellulose 3 and salt mixture 3 per cent. The starch was derived from raw or steamed maize, sweet potato or potato. Each rat was given 15 g. food daily, with free access to water, for 10 days; faeces were collected for analysis. In the second series 6 rats were given diets of starch 68, whole egg powder 23, butterfat 2, cellulose 3, salt mixture 3 and vitamin mixture 1; the daily food intake was 18 g. and the starches used were raw maize starch and raw, purified or autoclaved sweet potato starch. In the third series the same 6 rats as in the second series were given 18 g. daily of a low-protein diet of starch 77, whole egg powder 5, butterfat 10, cellulose 3, salt mixture 4 and vitamin mixture 1 per cent.; the starches were raw maize starch and raw sweet potato starch.

The coefficients of digestibility of raw maize, sweet potato and potato starch were 99, 97 and 57 per cent.; the differences were statistically significant. When steamed, all the starches were utilised almost completely and no significant difference was found. Raw sweet potato starch caused diarrhoea and decreased the apparent digestibility of protein; this effect was less when the starch was purified and disappeared when it was steamed. Raw potato starch was little utilised and also reduced the apparent digestibility of protein.—G. F. Garton.

KIK, M. C. **Nutrients in rice bran and rice polish and improvement of protein quality with amino acids.** *J. Agric. Food Chem.*, 1956, **4**, 170–172. [Dept. Agric. Chem., Univ. Arkansas, Fayetteville.]

Data are given for the contents of 17 amino acids in rice bran and rice polish, and for all the vitamin B complex components, together with Ca, P, Fe, protein, fat and ash.

In experiments with rats on a basal diet of which all the protein was supplied by either rice bran or rice polish the addition of 0·2 per cent. L-lysine plus 0·2 per cent. DL-threonine produced an increased rate of growth over 10 weeks of up to 16 per cent. The further addition of 0·1 μg. vitamin B_{12} to the diet supplemented with amino acids produced increases of 27 and 43 per cent. Protein efficiency ratios were also increased.

J. S. Thomson.

3506

EAGLE, E., BIALEK, H. F., DAVIES, D. L. and BREMER, J. W. **Biological vs. chemical evaluation of toxicity and protein quality of cottonseed meals.** *J. Amer. Oil Chem. Soc.*, 1956, **33,** 15–21. [Res. Labs., Swift and Company, Chicago, Ill.]

The free, total or combined gossypol content of 68 cottonseed meals given to rats as 67 per cent. of the diet was not correlated with toxicity. The protein quality of the meals was poorly correlated with the solubility of their N in 0·02 *N* NaOH.

A. Hepburn.

3507

LEE, J. G. **Detoxication of tung meal.** *J. Agric. Food Chem.*, 1956, **4,** 67–68. [Dept. Agric. Biol. Chem., Louisiana State Univ., Baton Rouge.]

Previous work on treated tung meals with chicks (Lee and Watson, *J. Amer. Oil Chem. Soc.*, 1953, **30,** 32) was repeated with rats. Tung nut flakes were extracted with Skellysolve B, air-dried and ground. The meal was extracted with ethanol, or moistened and steamed at 100° C. for 2 hr., or both, or extracted with ethanol and steamed dry. The treated meals, and untreated meal, formed 20 per cent. of a ration consisting otherwise of casein 20, dextrose 50, minerals 2, maize oil fortified with vitamins 5 and dextrose fortified with vitamins 3 ; details of the vitamin additions are given. There was also a control ration containing 25 per cent. casein and 2 per cent. Ruffex, with dextrose replacing the tung fraction. The rations were given for 21 days to paired littermate weanling rats in groups of 5, individually housed and fed to appetite. Mean weight gain and feed consumed per g. weight gain showed that the treated meals, except that extracted with ethanol and unsteamed, were comparable with the control ration, the best being the meal extracted with ethanol and steamed moist ; that is, the results with rats were similar to those with chicks. Discrepancies between the findings and those of Mann *et al.* (Abst. 4232, Vol. 24) are possibly explained by their omitting moistening before heating or by other differences in method.

In a further experiment, the casein of the ration was replaced by dextrose, so that the treated tung meal was the sole source of protein. When the modified ration alone or with supplements of 0·3 per cent. DL-methionine, 0·8 per cent. L-lysine hydrochloride or 0·1 per cent. L-tryptophan, or with additional amounts of tung meal, was given for 30 days to groups of matched littermate weanling rats, the results showed that lysine was the first limiting amino acid of the tung protein.

It is concluded that detoxified tung meals are not promising as economical protein supplements to cereals.—W. M. Deans.

3508

BOOTH, A. N. and DEEDS, F. **Chronic toxicity study of phytic-acid-treated soybean oil for rats.** *Food Res.*, 1955, **20,** 582–586. [U.S. Dept. Agric., Agric. Res. Serv., W. Utilisation Res. Branch, Albany 10, Calif.]

Weanling rats fed for more than 400 days on a basal diet containing maizemeal, casein and linseed cake meal and with 0·65 per cent. Ca did not show any evidence of toxicity as judged by growth and histology when soya bean oil treated with phytic acid (Evans *et al.*, *J. Amer. Oil Chem. Soc.*, 1953, **30,** 143) replaced 10 per cent. of the whole diet. Two per cent. phytic acid alone, with or without 0·7 per cent. Ca, produced a decrease in the rate of growth and testicular atrophy with this diet, but had no effect with a diet of Purina Chow which was inferior for supporting growth and contained 1·17 per cent. Ca.—A. Hepburn.

3509

WALKER, D. G. and WIRTSCHAFTER, Z. T. **Histopathogenesis of aortic aneurysms in the Lathyrus-fed rat.** *Arch. Pathol.*, 1956, **61,** 125–135. [Res. Lab., Med. Serv., Veterans Admin. Hosp., Portland, Oreg.]

Of weanling rats equally divided between the sexes, 8 were given a stock diet and 24 had pellets made from equal parts of the stock diet and seeds of *Lathyrus odoratus*. Massive aortic haemorrhage caused the deaths of 8 in the experimental group before they were due to be killed ; the survivors in fours and the control animals in pairs were killed at 6, 7, 8 and 9 weeks of age. The heart, aorta, and pulmonary and coronary arteries were examined both macroscopically and microscopically.

Only in the aorta of the experimental rats were intramural haematomas and dissecting aneurysm seen, but in the other vessels examined in rats from that group deficiency of elastic fibres and hyperplasia of fibroblasts were found. The dissecting aneurysm is thought to be a sign in the aorta of a more generalised elastolytic disorder. There are 23 illustrations.—D. Harvey.

3510

FALKMER, S. and KJELLGREN, K. **Morphologic and functional changes under hypothermia. An experimental study on rabbits with special**

reference to the liver. *Acta Soc. Med. upsalien.*, 1955, **60,** 199–223. [Dept. Pathol., Univ. Upsala.]

Adult rabbits of both sexes, weighing between 2 and 5 kg., were fed to appetite on turnips, hay and crushed oats with commercial feeding lime. The rabbits appeared clinically healthy, though postmortem examination showed that half of them had bacterial or mycotic lesions; since the incidence was similar in experimental and control groups the affected animals were not excluded, but numbers with and without lesions are given throughout the paper.

For experiments rabbits were anaesthetised generally with Nembutal and locally with Xylocain, and were given Ringer's solution intravenously to keep the water balance as nearly normal as possible.

Hypothermia was induced as described elsewhere (Kjellgren, *Acta Soc. Med. Upsal.*, 1953–54, **59,** 391); 13 rabbits served as controls. Cooling was such that rectal temperatures fell to between 28° and 30° C. Some rabbits were killed at the end of the experiment, others from 8 hr. to 153 days afterwards.

Morphological changes were confined to the liver and adrenals of rabbits killed immediately after the cooling experiment and were absent even in those allowed to live 8 hr. afterwards. Changes were typical of hypoxia.

Functional after-effects were slight. Some of the survivors subsequently reproduced. Secretion of bile and bile pigments was reduced during cooling, especially when cooling was intra-abdominal. The control animals showed during experiments a low prothrombin value and low prothrombin-proconvertin index, which were ascribed to the anaesthesia. These changes were absent in the hypothermic rabbits. Cooled rabbits had low serum protein values 24 and 48 hr. after re-warming, but not immediately after. The drop was mainly in the albumin fraction. No change was found in serum protein of controls.—D. Duncan.

FENTON, P. F. **Growth and fat deposition in the mouse. A definition of obesity.** *Amer. J. Physiol.*, 1956, **184,** 52–54. [Dept. Biol., Brown Univ., Providence, R.I.]

Weanling male mice of the C57 BL/Fn and I/Fn strains were fed on a diet containing Crisco 45 and maize oil 5 per cent. The animals were killed in groups at intervals up to 6 months and carcase fat was estimated.

The fat content of C57 BL/Fn mice increased linearly with age and with the fat-free weight of the animals until the third month of life. The fat content of all the I/Fn mice increased with the fat-free weight in a nearly constant ratio of 0·1. Obesity is defined as a significant increase in this ratio.—A. K. Lough.

3512

MICKELSEN, O., TAKAHASHI, S. and CRAIG, C. **Experimental obesity. 1. Production of obesity in rats by feeding high-fat diets.** *J. Nutrition*, 1955, **57,** 541–554. [Lab. Biochem. Nutrit., Nat. Inst. Arthritis Metabol. Dis., U.S. Pub. Health Serv., Bethesda, Md.]

Groups of male rats weighing about 300 g. were given either a high-fat diet of casein 25, sucrose 7, starch containing vitamins of the B group 1, salts 4, Crisco 60, vitamins A and D 2 and vitamin E 1 per cent., or a low-fat diet of casein 30, sucrose 61, vitaminised starch 2, salts 4, vitamins A and D 2 and vitamin E 1 per cent.; the remainder received a stock diet. After 36 weeks the rats on the stock diet weighed 425 g., those on the low-fat diet 417 g. and those on the high-fat diet 511 g. Even higher weights were attained more rapidly in animals which survived forced feeding with high-fat diets, but the difficulties of the procedure prevented its use as a routine method for securing large numbers of obese rats. More than 75 per cent. of the rats maintained on these diets for 6 months or more developed middle ear or upper respiratory infections.

Groups of 5 or 10 rats 3 to 4 weeks old were given the high-fat diet, the low-fat diet, Ingle's semi-liquid diet (Abst. 108, Vol. 20) or a stock food. The effect of penicillin added to these diets was studied and the intake of vitamins of the B group was doubled. The high-fat diets were supplemented with 5 per cent. whole liver powder and vitamin B_{12}. The growth rates of rats of the NIH black, Sprague Dawley and Osborne Mendel strains on the high-fat diets were compared. All rats received food to appetite. A group of weanling rats on the high-fat diet and one on Ingle's diet were kept under conditions of limited movement. The 3 strains of rats were found to have the same response. The maximum weight attained on the high-fat diet was 1655 g. About 70 per cent. of the rats of the Osborne Mendel strain attained weights over or close to 1000 g.

G. F. Garton.

ANLIKER, J. and MAYER, J. Comportement alimentaire de souris obèses et des souris normales. [**Feeding behaviour of obese and normal mice.**] *C.R. Acad. Sci.*, 1956, **242,** 285–286.

The mouse cage used was in a soundproof box and contained a mechanism which released food in 40-mg. tablets and recorded each time the mouse took one. The mice studied were rendered obese by hypothalamic lesions or by injection or had the syndrome of hereditary obesity and diabetes; each category had its controls.

Control mice showed a 24-hr. cycle of eating, but this periodicity was absent in the obese mice. The mice with hereditary obesity ate bigger meals

less often than those with induced obesity. Periods of satiety occurred in normal, but not in obese, mice. It is concluded that it is an elimination of the mechanism of satiety, not an increase in activity of centres controlling eating, which leads to hyperphagia and obesity in these mice.

FULLER, J. L. and JACOBY, G. A. (Jr.) **Central and sensory control of food intake in genetically obese mice.** *Amer. J. Physiol.*, 1955, **183,** 279–283. [Div. Behaviour Studies, R. B. Jackson Mem. Lab., Bar Harbor, Maine.]

When the standard Purina chow diet was diluted by addition of 45 per cent. cellulose and 5 per cent. gum arabic as binding agent, neither genetically obese mice nor their non-obese littermates could maintain bodyweight. When the dilution was only 5 per cent., growing obese mice showed reduced weight gains, but non-obese mice did not. When dilution was 25 or 35 per cent. the nutrient intake of controls even increased. Weight increase in obese mice ceased when dilution was 35 per cent.

When food was made bitter by inclusion of quinine or burnt sugar all the mice reduced their intake at first, but later the reduction of intake was greater in the obese than in control mice. When fat was added to the chow diet both groups reduced their bulk intake, but the reduction was greater in the controls.

It is concluded that the obese mice were less able to adjust their food intake and adapt themselves to changes in diet.—D. Duncan.

MAYER, J. and MARSHALL, N. B. Mode d'action de l'aurothioglucose et régulation glucostatique de la nutrition. [**Mode of action of gold thioglucose and glucostatic regulation of nutrition.**] *C.R. Acad. Sci.*, 1956, **242,** 169–171.

Gold thioglucose injected into mice at the rate of 1 mg. per g. bodyweight causes the death of about half the mice and produces obesity in half the survivors. Gold thiomalate has about the same toxicity, but does not cause obesity. Obesity caused by gold thioglucose is identical with that produced by hypothalamic lesions. Histological examination revealed haemorrhages, oedema and cellular degeneration in the ventromedial region of the hypothalamus in mice killed shortly after injection of gold thioglucose, but not in those given gold thiomalate. Gold thioglucoanilide and gold sodium thiosulphate were inactive. Lesions were produced in the hypothalamus of rats by gold thioglucose, but all the animals died within 3 days; apparently it is only the higher toxicity of the substance for rats which prevents the manifestations of hyperphagia and obesity. In mice simultaneous administration of sodium thioglucose prevented the effects of gold thioglucose on the hypothalamus.

The results support the theory that the ventromedial region of the hypothalamus contains " glucoreceptors ".—D. Duncan.

ALONSO, L. G. and MAREN, T. H. **Effect of food restriction on body composition of hereditary obese mice.** *Amer. J. Physiol.*, 1955, **183,** 284–290. [Res. Div., American Cyanamid Company, Stamford, Conn.]

The results of 3 tests are reported, in 2 of which only fat was estimated; the third was more intensive and included also measurements of water and protein contents. The systems of feeding were the same in all 3; a set of lean and one set of obese mice were fed to appetite, and another set of obese was pair-fed with the lean mice.

The first test, with 5 pairs of mice of opposite sex and 9 weeks of age at the beginning, lasted for 10 months. Three obese mice developed ulceration of the skin and were discarded. Although the obese mice on the restricted diet gained only slightly more weight than the lean, their percentage of body fat was more than double that of the lean mice. In the second test the 6 mice were 7 months old at the start and large depots of fat had by then been acquired by the obese animals. Restriction of their diet caused them to lose some weight, but their fat content remained about twice that of the lean group.

In the third test with 26 mice, habitual wastage of food by some of the obese on the restricted diet allowed their being grouped at 2 levels of reduced intake, namely, 4·1 and 2 g. daily; mean daily intake when feeding was to appetite was 7·6 g. for the obese and 5·4 g. for the lean mice. Weight gain of the lean siblings was between the rates for the 2 restricted groups. The percentages of fat, which differed significantly, were, for the groups in the above order, 34, 20, 42 and 12. For the obese mice the differences in average weight between the restricted groups and the unrestricted one were 24 and 39 g., but in terms of water, fat and protein the proportionate losses were about the same at both rates of restriction.

It is concluded that obese mice metabolise their food in a manner different from that of lean mice by depositing more fat per g. food eaten.

MAYER, J., ZOMZELY, C. and FURTH, J. **Body composition and energetics in obesity induced in mice by adrenotropic tumors.** *Science,* 1956, **123,** 184–185. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

There were 3 groups of mice of the same strain : 16 mice bearing pituitary adrenocorticotropic tumours, 14 also, with tumours but from which adrenals had been removed at the time of implantation, and 17 normal animals. Bodyweight was similar in the groups, about 27 g. Measurements were made of food eaten, of spontaneous activity and of oxygen consumption and, for some mice, fatty acids and cholesterol were estimated in the whole carcase and the liver. The findings for the groups in that order were, for food consumption, $5{\cdot}8 \pm 0{\cdot}9$, $5{\cdot}1 \pm 0{\cdot}7$ and $4{\cdot}8 \pm 1{\cdot}0$ g. daily and for activity, 4555 ± 2439, 4336 ± 1997 and 6024 ± 3003 revolutions daily. Oxygen consumption did not differ.

The chemical estimations showed that, although they were not overweight, the mice in group 1 were obese in that they had twice as much extrahepatic fat as the normal and 3 times as much as the adrenalectomised mice, and body cholesterol and the fatty acids and cholesterol in liver were similarly increased. [The findings have already been mentioned in the note added in proof to the Review Article by the senior author on p. 881, Vol. 25.]—D. Harvey.

NEDERVEEN-FENENGA, M. and DALDERUP, L. M. **Nutrition and caries. 4. Histologic investigation.** *J. Dent. Res.*, 1956, **35,** 39–48. [Netherlands Inst. Nutrit., Amsterdam.]

For part 3 see Abst. 2226, Vol. 24.

4. The 9 methods of staining which were used are described. They were applied to the study of the changes occurring in rat's molars before caries could be seen macroscopically. The process, similar to that described in human teeth by Barker (*J. Amer. Dent. Assoc.*, 1931, **18,** 17) and by Rosebury and Karshan (*J. Dent. Res.*, 1933, **13,** 379 ; *J. Amer. Dent. Assoc.*, 1944, **21,** 1599), is the appearance of lamellae running from the surface of the enamel to the boundary between enamel and dentine. It is accompanied by decalcification and depolymerisation of mucopolysaccharides. Some further lines of research are indicated which either are being or will be followed.

D. Harvey.

3519

DALDERUP, L. M. and JANSEN, B. C. P. **Nutrition and caries. 5. The influence of feeding cooked rations on experimental dental caries in the rat. 6. Influence of limited feeding on experimental rat caries with some remarks on the feeding of the parents. 7. The influence of yeast on experimental dental caries in the rat.** *Internat. Ztschr. Vitaminforsch.*, 1955, **26,** 192–199 ; 199–209 ; 209–219. [Netherlands Inst. Nutrit., Amsterdam.] German and French summaries.

5. The diets were a coarse maize diet (Abst. 569, Vol. 2), a diet based on the average food eaten by the Dutch population (see also Abst. 876, Vol. 26) and a highly purified ration (Title 3429, Vol. 18). Rats were given these diets ; for the experimental groups the change from the raw to the cooked form was made at weaning. The method of scoring was that of Keyes modified as already described (Abst. 2226, Vol. 24). Data are presented in summary form.

From the rate of growth of the rats there was no evidence that cooking had affected the nutritive value of anp of the diets. Its effect was greatly to reduce caries production by the first and second diets. On the third and highly purified diet, which was finely ground, the incidence of caries was low compared with that on the others and the change on cooking was much less than with them.

6. The change of incidence of caries produced by reducing intake of food has already received brief notice (Abst. 876, Vol. 26). Rats were fed on the Dutch diet either as eaten or after modification by the addition of yeast or by including more vegetables and potatoes and less sugar, meat and fat. The second of these changes also reduced the incidence of caries. There was no evidence that restriction in the feeding of a parent group affected the incidence of caries in its offspring.

The findings are discussed in relation to those of other workers. The effect of restricted feeding is thought to arise not from the smaller intake of food, but rather from its remaining in the mouth for a shorter time, the restricted animals having shown a distinct tendency to bolt their food.

7. The effects were studied of the addition of yeast to each of 4 diets, 3 of which were those already mentioned in part 5 ; the fourth was a diet devised by Bonting (Abst. 2379, Vol. 25) and resembling the average Dutch diet especially in its acid base balance. To the first 3 diets yeast was added at the rate of 5 per cent., other constituents being reduced accordingly ; the fourth already had 5 per cent. yeast and the effects were examined of removing the yeast from it and increasing other constituents accordingly.

The presence of yeast in 3 of the diets had no influence on the incidence of caries but with the fourth diet, Sognnaes's highly purified one (Title 3429, Vol. 18), the inclusion of yeast caused a distinct reduction of incidence.—D. Harvey.

MUHLER, J. C. **The effect of chronic inanition and frequency of food ingestion on the dental caries experience in the rat.** *J. Nutrition*, 1955, **57,** 441–445. [Dept. Chem., Indiana Univ., Bloomington.]

Five groups of weanling rats of both sexes, 160 in all, caged individually, had fluorine-free water and a stock maize cariogenic diet (Abst. 898, Vol. 26) as follows: (1) to appetite (controls), (2) 60 per cent. and (3) 40 per cent. of that eaten by the controls, (4) to appetite but only for 3 periods daily of ½ hr., (5) to appetite but only for 1 period daily of 1½ hr. After 140 days they were killed and caries was evaluated.

Restricted rats of groups 2 and 3 were found to have a great deal less caries than controls. There was a tendency for rats fed 3 times a day to have more caries than those fed only once, but the difference was not significant and may have been due merely to the greater amount of food eaten by the former. The results show that the increase in caries after pituitary removal (see Title 901, Vol. 26) was not due to the reduction of food intake. It is considered that the food intake of rats in experiments on caries should be taken into account.

OCKERSE, T. **Experimental periodontal lesions in the white-tailed rat in South Africa.** *J. Dent. Res.*, 1956, **35,** 9–15. [Dept. Health, Pretoria.]

Two groups each of 20 white-tailed rats (see Abst. 4885, Vol. 23) were given diets containing food yeast, salts and fish liver oil; one (A) had, per cent., sugar 79 and casein 8 and the other (B) had sugar 40, casein 25 and whalemeal 22. Some animals in each group showed periodontal lesions but, the study being of caries, these were not recorded. Further work was done with first litters from mothers on diet A, given diets similar in their contents of linseed meal, alfalfa meal and bone-meal, milk powder, brewer's yeast, fish liver oil and salts but differing in that one (C : 7 rats) had coarse yellow maizemeal 40 and sugar 30 per cent., and the other (D : 11 rats) whalemeal 10 and sugar 60 per cent. Feeding lasted 11 months for these groups. Two more groups (E and F) each of 7 rats from second litters were treated in the same way. There was a control group (G) on a stock diet. The numbers of animals showing lesions in the groups C to G in order were 2, 9, 7, 8 and 0.

Radiographic and microscopic illustrations from particular animals show the extent to which bone destruction occurred, but explanations of the cause of the lesions or of their appearing only between first and second molars could not be advanced.

DESSAUER, H. C. **Effect of season on appetite and food consumption of the lizard, *Anolis carolinensis*.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 524–526. [Dept. Biochem., Sch. Med., Louisiana State Univ., New Orleans.]

Colonies of 8 to 15 adult male lizards were made up at different seasons from animals recently captured. They were kept at 28° ± 2° C. in natural light for 1½ to 2½ months and fed on mealworms (*Tenebrio molitor*) to appetite, but starved for 4 days before being weighed. The energy value of the mealworms was estimated to be 2 Cal. per g.

Appetite was greatest in animals caught in June and July and least in those caught between October and April. Lizards stored fat throughout the summer, but especially towards autumn. Bodyweight and fat content declined progressively from autumn to the middle of January.

Liver N in lizards killed between January and April was on the average 0·717, S.D. 0·151 mg. per g. fat-free bodyweight, and increased to 0·976 ± 0·159 mg. by June, when it remained fairly constant until early winter.

The seasonal variation of appetite is thought to be correlated with changes in length of daylight.

DAVISON, J. **Body weight, cell surface, and metabolic rate in anuran Amphibia.** *Biol. Bull.*, 1955, **109,** 407–419. [Dept. Zool., Univ. Minnesota, Minneapolis.]

Respiratory rate was studied in frogs of 7 species with an approximately geometric series of bodyweights of about 1·0, 4·5, 6·0, 35·0 and 350·0 g. The frogs were fasting and inactive. The surface area per c.mm. of fibres from the gastrocnemius muscle was estimated from camera lucida drawings.

Within species the surface law, c.c. O_2 per hr. per g. $= kW^{-\frac{1}{3}}$ was valid. Three values for k were sufficient for all the species. There was also a species constant relating muscle cell surface to bodyweight, sq. cm. per c.c. $= k'W^{-\frac{1}{3}}$. Therefore metabolic rate and muscle surface are directly proportional and c.c. O_2 per hr. per g. $= k/k'$ sq. cm. per c.c. fibres. This was not valid between species. Buccopharyngeal frequency was a species constant and independent of bodyweight. If buccopharyngeal frequency represents central nervous activity, and if the respiratory system depends on muscle cell surface, nervous activity and muscle surface may interact *in vivo* in the control of respiration. Theoretical implications of the findings are discussed.—D. Duncan.

3527

SASSEN, A. Étude de la toxicité des acides aminés chez la grenouille. [**Toxicity of amino-acids for the frog.**] *Arch. internat. Pharmacodyn.*, 1955–56, **104,** 100–112. [Lab. Thérap. Exp., Univ. Louvain.]

Of 18 common amino acids tested, 17 were toxic when injected into frogs, the LD_{50} doses supplying from 0·115 to 3·0 mg. N. The exception was glutamic acid. The *d*-forms of arginine, histidine, phenylalanine and threonine were less toxic than the *l*-forms. Although the signs of poisoning were similar to those found after injection of heated proteins or of protein hydrolysates, it was considered that the toxicity of these was not explained by the liberation of amino acids. Glutamic acid injected with other amino acids did not modify their toxicity.—W. M. Deans.

3528

SCHJEIDE, O. A., LEVI, E. and FLICKINGER, R. A. **A study of the yolk proteins of frog eggs by physical and chemical means.** *Growth*, 1955, **19,** 297 – 306. [Div. Radiobiol., Atomic Energy Project, Univ. California, Los Angeles.]

From ultracentrifugal, electrophoretic and chemical analyses of vitellin and livetin derived from egg yolks and embryos of *Rana pipiens* at the oocyte and tailbud stages it was shown that the ratio of livetin to vitellin in the cells increased during development. Vitellin, it is suggested, may be the source of materials required for growth and differentiation processes as, for example, of inorganic P for incorporation into nucleic acids and of phospholipin for the fat-hydrolysing enzymes.

SWIFT, D. R. **Seasonal variations in the growth rate, thyroid gland activity and food reserves of brown trout (*Salmo trutta* Linn).** *J. Exp. Biol.*, 1955, **32,** 751–764. [Freshwater Biol. Assoc., The Ferry House, Far Sawrey, Ambleside.]

Samples of 50 fish from a population initially of 250 3-year-old brown trout in 2 ponds were measured monthly; in a second investigation there were 100 fish in a pond and all were measured and weighed monthly. A random sample of 9 fish monthly were killed and analysed. Nine others were used for estimation of thyroid activity 6, 24, 48 and 72 hr. after injection of ^{131}I.

There were 2 peaks of growth rate, one towards the end of April and one in August. Tissue analyses showed that muscle and liver remained remarkably constant in composition except that liver glycogen in females fell in autumn.

The main storage organ was the gut wall, which contained much fat in July and less in spring and autumn. Maturation of the gonads was complete in October, with a peak of protein content. There was a peak of thyroid activity in midsummer.

LIEBMANN, H. Ernährungsstörung und Degeneration als primäre Ursache der Bauchwassersucht bei Fischen. [**Nutritional disturbance and degenerative changes as the primary cause of abdominal dropsy in fish.**] *Berl. Münch. tierärztl. Wochenschr.*, 1956, **69,** 21–25. [Teichwirtsch. Versuchsanst., Wielenbach.]

The disorder of freshwater fish known as infectious abdominal dropsy, because this was the most characteristic sign, has in recent years

changed its character. Ascites has become less common, and the fish instead show numerous small or large ulcers, exophthalmos, anaemia and inflamed anus. Internal examination shows excess of fluid in the body cavity, discoloured liver and general inflammation, and especially characteristic haemorrhages in the swim bladder and muscles. The disorder, previously known only in carp, now affects trout, especially rainbow trout.

The spread of the infection is discussed, and it is concluded that some predisposing condition of the animal or the environment occurs. The artificial conditions of modern fish-farming, with overcrowding and artificial feeding, are blamed. Poor, weak covering with scales is conducive to infection and is ascribed to incorrect feeding. Nutritional studies are called for.—D. Duncan.

LUDWIG, D. and BARSA, M. C. **Oxygen consumption of whole insects and insect homogenates.** *Biol. Bull.*, 1956, **110,** 77–82. [Dept. Biol., Fordham Univ., New York 58.]

The insects studied were the Japanese beetle, *Popillia japonica*, and the mealworm, *Tenebrio molitor*. Eggs of both species, incubated at 30° C., and larvae and pupae of the mealworm were used at different stages; the oxygen consumption of the eggs or insects was compared with that of homogenates of the same stages, in a Warburg apparatus. Homogenation reduced the consumption of oxygen at all stages except in Japanese beetle eggs from the third to the sixth day of incubation. The degree of reduction depended on the stage of development. Intact mealworm pupae showed a U-shaped curve of respiratory rate during metamorphosis, but in the homogenates this curve was abolished. The greater the dilution of the homogenates, the greater the reduction in respiration.—D. Duncan.

EISNER, T. **The digestion and absorption of fats in the foregut of the cockroach, *Periplaneta americana* (L).** *J. Exp. Zool.*, 1955, **130,** 159–176. [Biol. Labs., Harvard Univ., Cambridge, Mass.]

Triolein oil, the glycerol ester of oleic acid, was digested *in vitro* by dilutions of crop fluid from cockroaches. Boiling the crop fluid prevented digestion of the fat, but addition of 10 per cent. $MgCl_2$ or 10 per cent. quinine sulphate did not. Starved or fed cockroaches fed on triolein were killed and were found to have hydrolysed part of the triolein; hydrolysis was delayed in the starved insects. Lipase was found histologically in the epithelium of all parts of the midgut and in the caeca, but not in the salivary gland, crop or hindgut. This was true also for *Blaberus craniifera* and *Blatta orientalis*.

Oleic acid was found in the intestinal cells 1½ hr. after a meal, light mineral oils after 6 hr. and heavy mineral oil only after about 5 days. Mixture with 3 or 15 per cent. of oleic acid greatly increased the rate of absorption of mineral oils and also of olive oil. Emulsions of olive oil were absorbed much more quickly when they contained crop fluid or extracts from the midgut of other cockroaches.

It is concluded that lipase secreted by the midgut and caeca of cockroaches passes forward into the lumen of the crop. Total degradation is not essential for absorption of fat in the foregut, but partial hydrolysis greatly accelerates absorption.

WATANABE, A., ITO, R. and SASA, T. **Micro-algae as a source of nutrients for daphnids.** *J. Gen. Appl. Microbiol., Tokyo*, 1955, **1,** 137–141. [Tokugawa Inst. Biol. Res.]

Daphnids are a favourite food of freshwater fish, so freshwater algae were investigated as food for daphnids. The daphnids were *Daphnia longispina* and *Moina macropa*, and the algae cultivated were the green algae *Chlorella ellipsoidea*, *Scenedesmus obliquus* and *Chlamydomonas* sp., and the nitrogen-fixing blue-green algae *Nostoc muscorum* and *Tolypothrix tenuis*. Measured quantities of algae and daphnids were kept in 300 ml. filtered pond water, in diffuse daylight at from 21° to 26° C., and the daphnids were counted at intervals. Green algae gave good rates of multiplication of both daphnid species; the blue-green algae were less effective, possible because they were filamentous and less easy to eat than the unicellular organisms.

Blue-green algae have been used to seed paddy fields because of their capacity for nitrogen fixation. Sometimes green algae have spontaneously appeared and blue-green algae have disappeared, with the appearance of daphnids. It is now realised from the results of the present research that daphnids, and green algae which promote their multiplication, must be excluded if the technique for enriching the paddy fields is to succeed.—E. M. Hume.

5. HUMAN DIET IN RELATION TO HEALTH AND DISEASE

DIET

REQUIREMENTS

3536

National Nutrition Council, South Africa. **Recommended minimum daily dietary standards.** *S. African Med. J.*, 1956, **30,** 108–111.

The standards proposed " should be regarded as adequate for the maintenance of health without allowing for a safety margin for ill-health, or for great individual differences in absorption and metabolism " and the figures given are " for nutrients in foods as consumed and do not allow for losses during transport, storage, preparation or serving ". The reference man and woman are taken to be 25 years of age, to weigh, respectively, 160 and 130 lb. and to be living in a climate with mean annual temperature 60° F. For the moderately active person the standards recommended are, for the man, Cal. 3000, protein 65 g., Ca 0·7 g., Fe 9 mg., vitamin A 4000 I.U. assuming 1/3 present as the vitamin, vitamin B_1 1, riboflavin 1·6, nicotinic acid 15 and ascorbic acid 40 mg.; for the woman, in the same order of nutrients, 2300, 55, 0·6, 12, 4000, 0·8, 1·4, 12 and 40. There are standards also for women during pregnancy and lactation and for children of both sexes up to 10 years and separately for boys and girls from 10 to 12, 13 to 15 and 16 to 20 years.

Amounts of energy for heavy workers are 4500 and 2800 Cal. for the man and the woman but, if the woman does heavy work in the fields, she may need considerably more than this. For lactation the energy requirement is taken to be 120 Cal. per 100 ml. milk produced. Reference is made to the extra Fe which local investigations have shown as likely to be derived from the iron pots commonly used by Bantu people for cooking.—D. Harvey.

3537

Solis, M. Demanda alimenticia de la población de la República de Panamá en 1950. [**Nutritional needs of the population of the Republic of Panama in 1950.**] *Serv. Interamer. Cooperacion Agric. Panamá*, 1955, Foll. No. 7, pp. 22.

The estimate of needs of the population of Panama is based on the census of 1950, which gave a total of 756,631 " civil " inhabitants and 48,604 Indians. The ages of 742,000 persons were known. Their requirements were estimated from the tables prepared by Reh (*Inst. Nutric. Centro Amér. Panamá, Publ. Cient.* E-54, 1952). With the addition of estimates for the needs of the infants less than 6 months old and for 6107 foetuses of more than 6 months' gestation, the total requirement of the whole population was calculated. It included for the year energy 586,883 Megacal., protein 16,571 metric tons, Ca 260 tons, Fe 3 tons, vitamin A 346 kg., vitamin B_1 289 kg., riboflavin 433 kg., nicotinic acid 2944 kg. and ascorbic acid 18,619 kg. Suggestions are made for the quantities of different foods needed to supply these amounts of nutrients; in order to supply the calcium requirement a much larger amount of milk would be needed than could at present be produced.—D. Duncan.

3538

Leverton, R. M., Gram, M. R., Chaloupka, M., Brodovsky, E. and Mitchell, A. **The quantitative amino acid requirements of young women. 1. Threonine.**

Leverton, R. M., Gram, M. R., Brodovsky, E., Chaloupka, M., Mitchell, A. and Johnson, N. **2. Valine.** *J. Nutrition*, 1956, **58,** 59–81; 83–93. [Nebraska Agric. Exp. Stat., Lincoln.]

1. The general procedure used in a series of investigations of the requirements of young women for 5 amino acids is described. The subjects were 35 healthy college girls, in age from 19 to 26 years, and the acids studied were threonine, valine, tryptophan, phenylalanine and leucine. A semi-synthetic basal diet of sugar, maize starch, butter, maize oil, lemon juice and jelly was used to which were added mineral and vitamin supplements and, to improve palatability, small amounts of auxiliary foods low in N, orange, tomato and grape juices, peaches, pineapple, raw carrot and lettuce, were allowed. The amino acids were given as a mixture of 12 in the proportions found in egg protein and in amounts equivalent to 15 or 20 g. protein. Nitrogen balance was studied as the amount of a particular acid was reduced and equilibrium was assumed if output was from 95 to 105 per cent. of intake. When all 5 acids had been studied a final test was made with a mixture containing the minimum amounts of each.

In the study of threonine requirement the auxiliary foods supplied, on the average, 30 mg. daily and the range of amounts required to maintain N equilibrium was from 103 to 305 mg. Of 21 subjects all were in equilibrium with 305 mg., all but 4 with 214 mg. and 2 were able to maintain it with 103 mg. No relation was found between amount of threonine and bodyweight or creatinine coefficient. The rounded amount of 310 mg. daily is suggested as likely to cover the needs of all normal young women like those studied.

2. In the study of valine requirements the auxiliary foods supplied, on the average, 100 mg.

daily. At the level of 650 mg. all of 7 women were in equilibrium or in positive balance; with 465 mg. 3 were in negative balance. At the level of 375 mg. 5 of the 7 were in negative balance; balances for the 2 others were irregular, but both had nausea and lost appetite. In the later trial with 650 mg. all of 8 women were in equilibrium. There was no relation between amount of valine and creatinine coefficient or energy intake.

The minimum requirement of women like these is taken to be 650 mg. daily.—D. Harvey.

3539

MITCHELL, H. H. **The need for calcium is flexible.** *Modern Med.*, 1955, **23**, 85–91. [Dept. Animal Nutrit., Univ. Illinois, Urbana.]

Studies of calcium metabolism in the last decade show that the amount of Ca required daily to give equilibrium or storage in animal or man depends on the intake to which the subject has been accustomed. The less the habitual intake, the more economically Ca is used; a sudden change from high to low intake means loss of stored Ca and gradual, often slow, adaptation to the new level. There is no evidence to suggest that saturation of stores, bone trabeculae, is necessary for health. The infant with small stores uses Ca more efficiently than older children and the pregnant and nursing woman may also be more efficient than average.

For these reasons, diet standards for Ca have little significance. On an incremental or turnover basis, needs decrease from 16·5 mg. per kg. body-weight in the infant to 2·5 to 4 mg. in childhood, increase to 5·5 mg. during adolescence and decrease to a very low level at maturity. Pregnant women require for the foetus amounts rising to 300 mg. daily at term and, for 500 to 800 ml. milk, 170 to 272 mg. Ca daily. All of these must be multiplied by factors varying from 2 or less to 5 or more, depending on the accustomed level and the foods from which the Ca is derived.—I. Leitch.

DEMPSEY, C. A., GREINER, T. H., BURCH, N. R., CHILES, D. and STEELE, J. **The human factors in long range flight.** *J. Aviation Med.*, 1956, **27**, 18–22. [Aero Med. Lab., Wright-Patterson Air Force Base, Ohio.]

Freedom of choice of tinned foods, but with a limit of twelve 8-oz. tins, was allowed to representative pilots when they underwent tests simulating 2 periods of 18 and 19 hr., respectively, of cruising to and from a target and 1 period of 19 hr. of continued vigilance over a target. With the protective clothing provided there was no evidence of physiological stress. Energy intake was about half the amount of 5000 Cal. normally provided for the period of 56 hr.—D. Harvey.

3541

MEYER, F. L., BROWN, M. L., WRIGHT, H. J. and HATHAWAY, M. L. **A standardized diet for metabolic studies: its development and application.** *U.S. Dept. Agric. Tech. Bull.* No. 1126, November 1955, pp. iv + 81. [Human Nutrit. Res. Branch, Agric. Res. Serv.]

In cooperation with the University and the Agricultural Experiment Station of Maryland, a standardised diet was developed, believed to be suitable for studies of requirement and utilisation of most nutrients except protein and amino acids.

In the first of the 4 sections of the bulletin the diet is described, with tables of nutrients and typical meal patterns. The diet consists of a "core" of natural and refined foods providing most nutrients in restricted amount, and 2 complements. The "core" foods are apples, pears, peaches, green beans, celery, lettuce, dried potatoes and unenriched cereals other than maize, with small amounts of beef, haddock, evaporated milk and specially prepared tomato purée to make the diet pleasanter. Complement 1 supplies more carbohydrate, protein or fat with little change in minerals or vitamins, from the following foods: cake flour, gluten flour, vitamin-free casein, gelatine, sugar, low-vitamin jellies, and fat. Complement 2 supplies additional minerals and vitamins in synthetic or purified form. For reference levels, *i.e.*, intakes regarded as reasonable for preliminary or equalisation periods, it was planned to adjust the quantities so as to give Cal. 2000, protein 60, fat 80, carbohydrate 250 g., Ca 700, P 1000 [erroneously headed g. in Table 4, p. 10], Fe 10 mg., vitamin A 4000 I.U., vitamin B_1 0·8, riboflavin 1·0, nicotinic acid 7, ascorbic acid 60 mg.; and of nutrients of which the amounts required by man are still doubtful, Cu 0·8, I 0·105, Mg 220, Mn 2, K 2100, Na 2400 (these 2 not including salt and baking powder), Zn 4, choline [misprinted as chlorine in Table 1, p. 4] 300 mg., cobalamin 5 μg., folic acid 100 μg., pantothenic acid 4 mg., vitamin B_6 0·8 mg., vitamin D 400 I.U. The diet as actually used (see below) differed slightly from this. The necessary adaptations for studies of requirement or utilisation of a particular nutrient, or of interrelationships of nutrients, are explained in detail.

The third section includes recipes and methods of preparing the foods, methods of administering minerals and vitamins, and methods for collection and analysis of samples of foods, urine, faeces and blood. The fourth consists of a brief review of the literature on adults' requirements of essential nutrients. A bibliography of 192 items is appended.

The second, and longest, section describes a metabolic study made on 6 women students in the spring of 1952 to test the acceptability of the diet

and the suitability of the reference levels and to study the effect of different fat intakes on the utilisation of other nutrients. There were eight 5-day periods; during the second 4, 3 of the subjects had their fat intake reduced to 28 g. by replacing butterfat by isocaloric amounts of sugar and jelly. The diet proved acceptable and all but 1 of the subjects maintained weight. The results are presented in tables and graphically for the subjects individually. A reduction of the fat intake did not significantly affect N retention, total faecal lipids and fractions, retention of Ca, Mg or P, or excretion of vitamin B_1, riboflavin or ascorbic acid. For the 6 subjects, mean retentions were: N 0·78 g., Ca 24 mg., P 34 mg., Mg — 26 mg., on intakes of N 10·97 g., Ca 728 mg., P 948 mg., Mg 182 mg. Mean urinary excretions were: vitamin B_1 67 μg., riboflavin 116 μg. and ascorbic acid 11 mg., on intakes of vitamin B_1 795 μg., riboflavin 976 μg., ascorbic acid 57 mg. There were great differences between individuals, not explained by differences in height, weight or age, and for these a hormonal origin is suggested. For future studies lower reference levels of vitamin A, 3000 I.U., vitamin D, 300 I.U., and ascorbic acid, 40 or 50 mg., are suggested.—W. M. Deans.

FEEDING OF INFANTS AND CHILDREN

3542

CHERRY, A. **Establishing breast feeding.** *Med. J. Austral.*, 1953, i, 844–845. [Largs Bay, S. Australia.]

The difficulties of establishing breast feeding are discussed. Feeding should be on reasonable demand till an adequate flow of milk is well established, and discipline and habit-training should not begin until then. Systems are often too rigid and, though applicable in hospital, they may not be suitable in the home.—E. M. Hume.

3543

ISBISTER, C. **Breast feeding.** *Med. J. Austral.*, 1954, ii, 486–488. [Sydney.]

The article is a general one furnished by special request, and is intended primarily for clinicians. It pleads for more ease in the management of breast feeding and for co-operation between doctors and health centre sisters to establish and maintain lactation in the 80 per cent. of women who are physically and psychologically capable of feeding their infants. A great many important points in the management of lactation are made.

E. M. Hume.

3544

MILLIS, J. **Some aspects of breast feeding in Singapore.** *Med. J. Malaya*, 1955, **10,** 157–161. [Dept. Social Med. Pub. Health, Univ. Malaya.]

The duration of breast feeding was studied in 3 groups of women delivered of single, mature infants without congenital defect in a maternity hospital. There was no history of abnormality during pregnancy and delivery. The groups were 106 Southern Indian women of the lower income groups, 103 Chinese women of the lower income groups and 114 Chinese women of the middle and upper income groups of urban Singapore. Thirty-eight Indian women, 30 poor Chinese and 59 wealthier Chinese weaned their babies before the twelfth week. The principal reason given was failure of lactation in all 3 groups, but in the last group employment of the mother away from home and indifference of the mother were of importance also. The incidence of breast feeding in the wealthier Chinese women was similar to published data for women in Britain; the incidence in the other groups was uniformly higher than for British women. Indian women were less successful in breast feeding than the poor Chinese women. In the former only, poor lactation was associated with high parity and low maternal age. See also Absts. 2634, Vol. 25 and 3582, Vol. 26.—F. C. Aitken.

SAINZ DE LOS TERREROS AMÉZAGA, C. Abuso en el empleo de las leches enteras acidificadas. [**Use and misuse of acidified whole milk.**] *Medicamenta*, 1956, **25,** 106–107. [Madrid.]

Although acidified whole milk is valuable in some pathological conditions, it is not to be regarded as a suitable diet for the healthy infant. Some infants are intolerant of it from the start, others develop dyspepsia or an intractable and protracted loss of appetite leading to failure to gain weight. A plea is made for care in its use.

D. Duncan.

3546

CUTILLO, S. Considerazioni su taluni aspetti della fisiologia dell'alimentazione nel corso dell'allattamento artificiale. [**Discussion of certain aspects of the physiology of nutrition during artificial feeding.**] *Lattante*, 1955, **26,** 462–474. [Ist. Clin. Pediat., Univ. Naples.] English summary.

The use is described of 2 types of milk powder acidified with lactic acid, one of whole-cream milk, the other with the percentage of fat reduced, the respective energy values being 475 and 432 Cal. per 100 g. By mixing and diluting them to different extents, diets of widely varying composition were obtained for babies of all ages and nutritional states; transitional diets also could easily be prepared. Such milk mixtures were satisfactory when given to 39 infants, normal, premature and dystrophic, up to 5 months of age. The rates of weight increase and values for serum protein, Hb and number of red cells are tabulated.—E. M. Hume.

SOGANDARES, L. Programas de alimentacion suplementaria como medida preventiva en la desnutricion infantil. .[**Programmes of supplementary feeding for preventing malnutrition among children.**] *Bol. Ofic. sanit. panamer.*, 1955, **39**, 464–468. [Serv. Nutric., Dep. Salud Pub., Panama.]

The plans promoted by UNICEF for improving nutrition of schoolchildren, pre-school children and infants in Panama are briefly outlined with some conclusions and recommendations mainly concerned with the problems of obtaining co-operation from parents, medical authorities and social workers in order to carry out the programmes of dietary supplementation.—A. M. Copping.

3549

MOORE, M. C., GOLDSMITH, G. A., BUTLER, R. E., WOLF, M. H. and MARTIN, M. P. **Effect of nonfat dry milk solids on growth and nutriture of children.** *J. Amer. Dietetic Assoc.*, 1955, **31**, 1223–1227. [Louisiana Dept. Health, Sch. Med., Tulane Univ., New Orleans.]

In a rural area, where milk consumption was low, children in one school were given a daily supplement to the school lunch of non-fat milk solids equivalent to 0·67 pint milk. In 43 children in this school and 43 comparable controls in a second school where no supplement was given nutritional state was assessed and height, weight, pelvic width and calf circumference were recorded at the beginning, during and at the end of the 14-month experiment. The only significant results of the milk supplement were a greater gain of weight in boys receiving the supplement compared with controls and a greater percentage in the supplemented group of children whose skin improved during the experiment.—F. C. Aitken.

3550

MACK, P. B., MILSOM, A. K. and CARNEY, P. L. **A study of two levels of bread enrichment in children's diets.** *Monogr. Soc. Res. Child Development*, 1953 (1955), **18**, Serial No. 57, No. 2, pp. 92. [Nelda Childers Stark Lab. Human Nutrit. Res., Coll. Household Arts Sci., Texas State Coll. Women.]

The children from 3 of the 4 orphanages taking part in the bread study had previously been subjects of an experiment to compare a low-meat diet with a high-meat diet. At the end of the meat diet study, children in the 3 institutions were given the basal diet of the bread study with enriched bread for 4 months. During this period the children in the fourth institution had their usual diet with unenriched bread. In the following 36 months all 4 institutions had the basal diet modified as follows: institution 1, bread with double enrichment for 18 months, unenriched bread for 18 months; institution 2, bread with ordinary Federal enrichment for 36 months; institution 3, bread with ordinary enrichment for 24 months, bread with no enrichment for 12 months; institution 4, bread with no enrichment for 18 months, bread with ordinary enrichment for 18 months. The intakes of nutrients from the basal diet with unenriched bread approached the allowances recommended by the National Research Council. The age distribution in any one institution was kept relatively constant by dropping a few older children from time to time and adding younger children. In institutions 1, 2 and 3 the average number of children, aged 6 to 14 years, was 40 in the different periods of study and there were 15 in institution 4.

The criteria used to assess the influence of enrichment of bread on nutritional status were: overall medical rating, bodyweight and growth, skeletal maturation of hand and bone density, condition of the eye, tongue, gums and skin, heart dysfunction, appearance of fatigue resistance, reflex activity, nervous habits, dark adaptation, Hb, red cell count, haematocrit, mean corpuscular Hb concentration (M.C.H.C.), mean corpuscular Hb (M.C.H.), blood levels of vitamin A, carotene, ascorbic acid, proteins, Ca, P and phosphatase, and urinary excretion of vitamin B_1, riboflavin and the nicotinic acid excretion product F_2. For each criterion standards were adopted for classification of children. The percentage monthly changes in percentage of children in designated classes, shown diagrammatically, were the ultimate bases of assessment of the value of bread enrichment. When improvement in rating, occurring during consumption of enriched bread, was increased during subsequent consumption of unenriched bread the effect was termed a carry-over.

Ordinary enrichment was associated with improvement in overall medical rating (with carry-over), development according to Wetzel grid, skeletal status, resistance to fatigue, response to test for reflex action (with carry-over), M.C.H.C. and M.C.H., skin and tongue condition, incidence of corneal vascularisation and urinary excretion of B vitamins. Favourable changes were in general more extensive with double than with single enrichment.—F. C. Aitken.

DIETARY SURVEYS AND INDIVIDUAL STUDIES

3551

EPSTEIN, F. H., CAROL, R. and SIMPSON, R. **Estimation of caloric intake from dietary histories among population groups.** *Amer. J. Clin. Nutrit.*, 1956, **4**, 1–9. [Res. Dept., Sidney Hillman Health Centre, New York.]

In this study it was assumed that the energy intake of a person of steady weight can be predicted from surface area by the use of the nomogram of Boothby *et al.* (Abst. 3555, Vol. 6), and that the predicted value can be used to check the accuracy of dietary histories. Of the 317 men and women interviewed, about one-third gave histories of energy intake agreeing within ± 10 per cent. with the predicted intakes; two-thirds agreed within ± 20 per cent., and 85 per cent. of the men and 75 per cent. of the women gave histories of energy intake within ± 30 per cent. of predicted intakes. It is concluded that dietary histories appear to provide a valid basis for the estimation of the food intake of population groups but not of individuals.—F. C. Aitken.

3552

JOHNSON, M. L., BURKE, B. S. and MAYER, J. **Relative importance of inactivity and overeating in the energy balance of obese high school girls.** *Amer. J. Clin. Nutrit.*, 1956, **4**, 37–44. [Dept. Maternal Child Health, Harvard Sch. Pub. Health, Boston, Mass.]

Diet histories and a picture of physical activity were obtained by interview from 28 obese and from the same number of normal girls. Intake of energy by obese was significantly less than by normal girls, but these normal girls were significantly more active than the obese.—F. C. Aitken.

3553

LYONS, J. S. and TRULSON, M. F. **Food practices of older people living at home.** *J. Gerontol.*, 1956, **11**, 66–72. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Diet histories were obtained in interviews with 100 men and women aged 65 years or over. The nutrients most frequently low were Fe, Ca and vitamin C in the women's and energy, Ca, vitamin B_1 and riboflavin in the men's diets. Thirty-five per cent. of the men and 52 per cent. of the women had more than the allowances of energy recommended by the U.S. National Research Council. Forty-eight per cent. of the men and 57 per cent. of the women were overweight by 10 per cent. or more.—F. C. Aitken.

3554

HOBSON, W. and PEMBERTON, J. **The health of the elderly at home.** *Brit. Med. J.*, 1956, i, 587–593. [Dept. Social Indust. Med., Univ. Sheffield.]

A general account is given of a survey of the health, diet and blood biochemistry of 476 elderly people living at home. Some of the more detailed results have been published in other journals (see, *e.g.*, Absts. 4841, Vol. 23; 2081, Vol. 24).

The incidence of specific causes of ill health and disability ranged from scurvy, found in 0·4 per cent., to errors of refraction requiring spectacles for their correction, found in 97·5 per cent. Cardiovascular conditions were responsible for more disability than any other condition.

The intakes of energy and nutrients of those graded as fit are tabulated by age group and it is suggested that these mean intakes provide average standards of adequacy for the elderly.

Estimations were made of Hb and blood urea, and of Ca, cholesterol and alkaline phosphatase in serum; means and range of values are tabulated.

F. C. Aitken.

3555

SAINT, E. G., ABRECHT, H. F. and TURNER, C. N. **Old age: a clinical, social and nutritional survey of seventy patients over sixty-five years of age seen in a hospital out-patient department in Melbourne.** *Med. J. Austral.*, 1953, i, 757–764. [Clin. Res. Unit, Walter and Eliza Hall Inst. Med. Res., Melbourne.]

Most of the 30 men and 40 women examined had come to the out-patient department with gastro-intestinal complaints, and major operations were performed on 33 with excellent results. Other disabilities of old age were recorded. The patients were classed in 4 grades according to their general health and capacity for physical activity.

The social survey included marital status, income and housing, mental adjustment to ageing, and employment.

The standards of the Oxford Nutrition Survey were used to assess dietary status. It was excellent in 12 patients, good in 31, borderline in 24 and inadequate in 3. Their dietary habits were particularly influenced by their energy expenditure, facilities for preparing meals, state of dentition, income, presence and degree of alcoholism, food habits and ignorance of food values. Patients living in their own homes were better off in every respect.

Advice about properly balancing the diet and about energy intake produced good results.

M. H. Pierce.

3556

MCGARY, V. E., SHIPMAN, M. E. and BERNSTEIN, L. M. **Acceptability of irradiated foods. Dietary procedures.** *J. Amer. Dietetic Assoc.*, 1956, **32**, 123–127. [Med. Nutrit. Lab. Fitzsimons Army Hosp., Denver.]

The test foods were canned and frozen and alternate cans were sent to be sterilised by irradiation with mixed fission products. The test foods were peaches, strawberries, ground beef, ham and bacon, haddock, green beans, beets, cereal bar, bread and powdered milk. These contributed 35 per cent. of total calories in the diet during balance and acceptability studies. The preparation and serving of the foods and the methods of analysing the diets in the balance studies are described. The results of the balance studies will be reported later. In 9 subjects there was little difference in acceptability of irradiated and non-irradiated foods.

3557

CARRÉRE, P. Enquète sur le budget familial par carnets de comptes annuels à Marseille. (mars 1953 à février 1954). [**Study of family budgets in Marseilles by questionnaire on annual expenditure (March 1953 to February 1954).**] *Bull. Inst. nat. Hyg., Paris*, 1955, **10,** 685–720.

For accounts of a previous survey see Absts. 5106, Vol. 24; 2571, Vol. 25; *Bull. Inst. Nat. Hyg., Paris*, 1955, **10,** 407. The present survey, on the same lines, covered 60 families with 236 persons, some, but not all, the same as before. Expenditure on food was highest in winter, and ranged from 38·5 to 54 per cent. of total expenditure and from 200 to 322 fr. per head daily, mean 242 fr., in 5 groups classified by total expenditure; but the mean cost per Cal. and the proportions of total energy furnished by carbohydrate, protein and fat were almost the same in all groups. Animal protein and Ca intakes were low; consumption of meat, fish and cheese was fairly high but that of milk, eggs and fresh vegetables low. Seasonal variations in consumption of different foods were not great, apart from fruit and vegetables. Intakes of energy and fat were highest in summer, largely owing to the use of salad oil.

Disadvantages of the method of survey are discussed and the interview method is considered to offer wider possibilities.—W. M. Deans.

3558

CARRÈRE, P. Étude sur le genre de vie des chômeurs (novembre-décembre 1954-janvier 1955). [**Mode of life of unemployed, November-December 1954-January 1955.**] *Bull. Inst. nat. Hyg., Paris*, 1955, **10,** 883–919.

As a sequel to studies of dockers (Abst. 2703, Vol. 22), large families (Abst. 4918, Vol. 23) and tradesmen (Abst. 1009, Vol. 24) in Marseilles, a survey was made in the winter of 1954–55 of a random sample of registered unemployed. There were 139 families with 506 persons, classified in 4 groups: head of household unemployed, no other earner, with children, 48 families, without children, 22, with other earner, 28; head of household working, other member unemployed, 41. Barely half were receiving unemployment benefit. The percentage of total expenditure devoted to food was 58, 52, 63·5, 53·5 in the 4 groups. Only 99 families supplied information about diet. Mean daily expenditure on food was 212, 264, 243, 270 fr., mean energy intake 2134, 2489, 2561, 2533 Cal. In general, intakes of animal protein and Ca were below standard, owing to ignorance of the value of dairy products and the high price of meat and fish and (in winter) of green vegetables. Group 1 had the most ill balanced diet, with too little meat, eggs, cheese, milk and fresh vegetables; these families used a lot of cereals, especially pastes and rice and dried vegetables; fat intake was adequate, but it was mostly oil. The amounts of foods they consumed were much the same as in the unemployed group in the survey of large families, except that the latter had more bread and milk and less cheese and fresh vegetables. Over the whole sample, the commonest reaction to unemployment was to reduce expenses all round, though some preferred to cut down expenditure on food, others on clothing or amusements.—W. M. Deans.

3559

DEAN, W. T. **Nutritional status of women industrial workers in Virginia.** *J. Amer. Dietetic Assoc.*, 1956, **32,** 24–28. [Virginia Agric. Exp. Stat., Blacksburg.]

Studies were made on 103 women, of whom 50 were employed in a government arsenal and 53 in a garment factory. Seven-day food records were collected for each subject when the study began in the autumn of 1952 and when it ended 12 months later. At the end of the first 6 months information was collected by the 24-hr. recall method. The mean daily intake of 9 nutrients was calculated and the data are tabulated according to age group and in comparison with U.S. National Research Council (1953) recommendations (Abst. 3538, Vol. 24). Physical examinations were made at the beginning and end of the study. At the beginning of the study and at 6-month intervals finger-tip samples of blood were analysed for Hb, vitamin A, carotene and ascorbic acid.

Only a small percentage of the women were poorly developed physically; except for gingivitis, changes in the papillae, caries and neurological conditions there were few abnormalities. In the autumn of 1952 and 1953, with some exceptions, no more than 9 per cent. of the subjects had intakes of nutrients two-thirds or less of the recommended allowances. From the 24-hr. recall studies in the spring of 1953, between 17 and 48 per cent. of women had daily intakes of Fe, Ca, vitamin A and ascorbic acid which were less than two-thirds of the recommended allowances.

According to standards which are described the levels of blood constituents were classified as good, fair or poor ; few were poor. There was evidence that the recommended allowances of ascorbic acid and vitamin A are greater than the amounts necessary to maintain levels in the blood that may be considered satisfactory.—G. F. Garton.

3560

BRINE, C. L. and TATE, E. B. **Effect of food losses on nutritive content of diets in four institutions.** *J. Amer. Dietetic Assoc.*, 1956, **32,** 19–23. [Arthur D. Little, Inc., Cambridge, Mass.]

Diet studies were made on all or on a representative sample of the persons living in 4 institutions in the United States during a 14-day survey period in either the winter or the summer of 1953 or in the summer of 1954. The population in 3 of the institutions, of which 2 were for old people and 1 for children, ranged from 90 to 804 ; in the fourth, a children's home where the food was prepared in cottages each with 15 residents, 2 such cottages, a boys' and a girls', were surveyed. During the study period, data were collected on the weight of food delivered to the kitchen, on the weight of inedible refuse and on the weight of food lost during preparation and serving of meals. The losses were expressed in terms of weight purchased.

In terms of weight, food losses in the 3 large institutions were high, from one-fifth to one-fourth of the total food issued. In the cottages the loss was 5 per cent. During preparation and serving there were losses from all foods, greatest from leafy, green and yellow vegetables, potatoes and sweet potatoes, meat, poultry and fish, and dry beans and peas and nuts and least from milk, cream, ice-cream and cheese, citrus fruit and tomatoes. Loss of nutrients was highest for Fe and nicotinic acid and lowest for Ca and riboflavin. In the large institutions the losses for the nutrients studied ranged from 13 to 38 per cent. ; in the cottages they were from 3 to 10 per cent.

When compared with U.S. National Research Council (1948) standards, nutrients in food issued in all 4 institutions were adequate, but in food eaten in the 2 institutions for the aged there were deficiencies of Fe in both, vitamin A and nicotinic acid in one and ascorbic acid in the other. Relative to recommended allowances, the values for the children's institutions were higher than those for the old.

It was thought that kitchen practices in institutions would cause losses of nutrients greater than would be found in family circumstances, vegetables and meats often being boiled or kept hot for long periods and the cooking water being thrown away.

G. F. Garton.

3561

SCOTT, E. M. **Nutrition of Alaskan Eskimos.** *Nutrition Rev.*, 1956, **14,** 1–3. [Arctic Health Res. Centre, Pub. Health Serv., Anchorage, Alaska.]

This short paper describes the change in feeding habits, from a diet rich in protein to a more mixed one with cereals and sugar as cheap sources of energy, which is taking place as Eskimos in Alaska forsake their traditional existence in small communities of a few families for life in villages of a hundred or more persons. In these villages which are growing up around schools, churches and stores the settlers have had difficulty in maintaining the herds of reindeer, which require nomadic conditions, and supplies of imported foods arrive only twice a year. Long-term problems arise if attempts are made to raise the economic status of the Eskimo either by encouraging migration to the larger centres of white population or by developing the resources of the tundra where he lives. In a city his lack of education places him low in the economic scale, and hitherto the development of local resources has not been achieved.

The outlook, though bleak, is not considered hopeless, since an innate adaptability may ensure his survival in a white civilisation.—D. Harvey.

3562

VÉLEZ BOZA, F. Estudio de la alimentación en un grupo de colectividades de Caracas durante los años de 1953–54. [**Diets of a group of institutions in Caracas during the years 1953–54.**] *Arch. venezol. Nutricion*, 1955, **6,** 35–47. [Inst. Nac. Nutrición.] English and German summaries.

Inventories of food were made for a week in 10 institutions : a children's home, a pre-natal and a post-natal home with 213 persons ; 6 private schools with 279 persons and an " official " school with 202 persons. Standards for requirements were those of Liendo Coll and Bengoa (Abst. 2548, Vol. 25) for energy and of the U.S. National Research Council (Abst. 3538, Vol. 24) for protein in terms of protein calories, equivalent to 13 per cent. of calories from protein at 1 to 3 years of age and about 8 per cent. for those over 20. Fat requirement was taken as 30 per cent. and carbohydrate at 55 per cent. [as stated].

In institutions in which the diet was sufficient the cost of food per head daily in bolivars ranged from 1·31 to 2·51 and where it was insufficient from 0·30 to 1·29. Diets in the private schools and the public assistance homes on the average were inadequate in energy value but had enough protein ; the " official " school had a large surplus of all proximate nutrients ; in detail, the pre-natal home and one of the private schools had adequate diets.—I. Leitch.

3563

FÉRY, R. L'Aurès. [**The Aurès.**] *Presse méd.*, 1956, **64,** 219–222.

This description of the partly nomadic Berber people of the Aurès, a mountainous region of Algeria to the north-east of Biskra, includes some notes on their food habits.

The staple food is semolina made from barley or maize; wheat is merely a means of exchange. The cereal is made into "galettes" (girdle-cakes) and "couscous"; for the latter coarse barley semolina is steamed, mixed with oil, moistened with a broth of meat and vegetables and spiced with cloves, coriander and pimento. These two foods, with dates, form most of the diet. Meat is rarely eaten fresh but is dried and eaten in small quantities in "couscous". Milk is made into butter and cheese; the usual beverage is whey. Besides dates, dried apricots and, in season, pomegranates, watermelons and grapes are eaten. Food is adequate in quantity, but the diet is monotonous and too high in carbohydrate. The people have communal stores for food and other possessions.

The women are not kept indoors; they attend to hens and goats and help at harvest time. They have no special routine or diet during pregnancy. Infants are wrapped in swaddling clothes and never washed. They are breast fed on demand, 2 years for a boy, 18 months for a girl, but are given "galettes" and dates very early. Rickets is unknown in the region. The weaned child gets the family diet and later may find and eat herbs and clay; infestation with worms is common.

The rest of the article deals with non-nutritional diseases. Disease is ascribed to evil spirits, cold and accidents.—W. M. Deans.

3564

SMARTT, C. G. F. **A note on the value of dried milk as an addition to the normal African diet in institutions.** *E. African Med. J.*, 1956, **33,** 27–30. [Mirembe Hosp., Dodoma, Tanganyika Territory.]

Male mental patients aged from 25 to 35 years when given a good African diet including 4 oz. meat 5 times a week showed a small continuous rise in weight which was greatest during their first 6 months in hospital and which gradually decreased with the length of stay in hospital. The addition of 4 oz. dried milk daily to the diet of 20 patients receiving such a diet caused an increase in average weight gain, large when compared with that of similar subjects not given dried milk. In 4 weeks the mean weekly gain was $5\frac{1}{4}$ lb. in those given milk and only $1\frac{1}{2}$ lb. in those not given it; in patients who had been over 2 years in hospital at the time of the trial the corresponding figures were $4\frac{1}{4}$ lb. and $\frac{1}{4}$ lb., respectively, which suggests that even a "good" African diet is deficient in some way that milk can correct.—L. Wills.

3565

GOVIL, K. K., BHATNAGER, D. P. and PANT, K. C. **Dietary habits in Uttar Pradesh in relation to income.** *J. Indian Med. Assoc.*, 1956, **26,** 138–141. [Provincial Hyg. Inst., Lucknow.]

In continuation of previous work (Absts. 1049, 3560, Vol. 24) a diet survey on 238 families (1489 persons) was made during 1952, 1953 and 1954 [period for which a single family was studied not clear]. The families were classified by monthly income per consumption unit in rupees: group 1 (147 families, 1021 people) had 30 R. or less; group 2 (34, 234), 31 to 40 R.; group 3 (32, 144), 41 to 50 R.; group 4 (25, 90) over 50 R.

Wheat, rice, both raw and parboiled, cheap grains, *i.e.*, barley, bajra (*Pennisetum typhoideum*), juar (*Sorghum vulgare*) and maize, and peas were all used. As income increased, wheat tended to replace rice, cheap grains and pulses, and ghee to replace cheaper vegetable substitutes; and except for green leafy vegetables, which were eaten in similar amounts by all groups, more vegetables, fruit and milk were used. Nearly half the families took meat and other non-vegetarian foods, but intakes were irregular and bore no relation to income. A table of daily intakes per consumption unit in oz. is included. For the 4 groups the respective daily intakes of energy and nutrients per consumption unit were: energy, 2857, 2942, 3030, 3206 Cal.; animal protein 5·7, 14·7, 12·9, 15·3 g.; vegetable protein 73·7, 68·0, 69·5, 72·9 g.; fat 40·3, 64·9, 69·9, 83·9 g.; carbohydrate 543·3, 505·4, 516·6, 521·4 g.; Ca 688·5, 900·1, 900·5, 1095·7 mg.; Fe 39·0, 38·4, 39·1, 44·0 mg.; vitamin A 2199, 2589, 2828, 3641 I.U.; vitamin B_1 2·0, 2·1, 2·2, 2·4 mg.; riboflavin 1·1, 1·3, 1·3, 1·5 mg.; nicotinic acid 18·2, 19·3, 20·5, 22·1 mg.; ascorbic acid 50·3, 54·3, 60·3, 74·9 mg. Groups 1 and 2 were considered to be having too little energy and all groups too little animal protein; intakes of Ca and vitamin A were adequate only in Group 4 and vitamin C only in groups 3 and 4. The mean monthly incomes were 19·3, 34·2, 48·0 and 74·0 R. and the expenditures on food 17·2, 24·5, 24·6 and 28·4. The monthly cost of a balanced diet in Uttar Pradesh was reckoned to be at least 34 R., including condiments and fuel. It was concluded that lack of means would prevent groups 1 and 2 from doing any better (2/5 of the families in group 1 were in debt or living on reserves) but that people in groups 3 and 4 should be educated into using more green vegetables and milk or other animal protein.—W. M. Deans.

3566

WILSON, W. **A dietary survey of aborigines in the Northern Territory.** *Med. J. Austral.*, 1953, ii, 599–605. [Austral. Inst. Anat., Canberra.]

A survey of dietary intake, food consumption patterns and eating habits of 2486 aborigines living in 5 government settlements, 6 missions and 6 cattle stations in the Northern Territory of Australia was made in August, September and October, 1951, towards the end of the dry season. Most of the food was issued as rations ; some of it was as cooked meals and some was uncooked. A modified "food list" and questionnaire method were used. According to the rations consumed, the aborigines were divided into 38 groups.

The main items of diet were flour or bread, meat, sugar and tea. Compared with the consumption of the average white Australian, the mean consumption per head by aborigines of cereals, flour and bread was greater by almost 100 per cent., and of sugar and meat by 30 per cent. Tea consumption was about the same, but that of milk, vegetables, fruit, potatoes, fats and eggs was less than half. Meat was the only food produced locally in sufficient amount to provide a regular supply for the aborigines. The cost and difficulties of transport restricted the variety of other foods, especially as some centres received supplies only 3 times in a year. The contribution of indigenous foods to the diet was not significant.

The food consumption was evaluated in terms of specific nutrients, and the intake of each group studied was compared with the recommended dietary allowances (restricted) of the Food and Nutrition Board of the National Research Council of America. Over 80 per cent. of the groups were receiving the recommended allowances of calories, protein and vitamin B_1, but a large number were grossly low in their intake of vitamins A and C and of Ca. When classified into grades by a descending scale from A to E (Abst. 2341, Vol. 17), 84 per cent. of the diets were in grade D or lower, compared with 26 per cent. of 2593 Australian households previously surveyed.

The food consumption and nutrient intake of working stockmen were better than in the other groups. Only some missions and government settlements provided special rations for pregnant or lactating women and children. The standard of cooking by employed cooks or the aborigines themselves was generally poor.—M. H. Pierce.

DEN HARTOG, C. and DE HAAS, J. H. Enquête naar het melk- en kaasverbruik bij schoolkindern op het platteland. [**Inquiry into the consumption of milk and cheese by rural schoolchildren.**] *Voeding,* 1956, **17,** 12–26. [Voorlichtingsbur., Voedingsraad, The Hague.] English summary.

The inquiry was made by school medical officers and covered over 5000 children in 49 school medical districts. The record form is reproduced ; the results are summarised by province and shown in tables and diagrams with legends in Dutch and English. The method of interrogation by interested doctors may have overestimated habitual use of milk and cheese.

Consumption was higher in the north and west than in the east and south. If 500 ml. milk daily and 100 g. cheese weekly be taken as desirable standard, half or less than half the children in the east and south attain that standard. Consumption per head was less in larger families and children had less than adults.—I. Leitch.

3572

DEN HARTOG, C. De betekenis van het melkgebruik voor de Nederlandse bevolking. [**Significance of milk for the Netherlands population.**] *Voeding,* 1956, **17,** 9–11.

Of the following nutrients, as shown by the 1953 inquiry of the Food Department of the Ministry of Agriculture, Fisheries and Food, milk at 580 ml. per head daily supplied, in percentages, Ca 76·3, animal protein 53·3, riboflavin 56·1, P 38·5, vitamin B_1 17·1, vitamin A 24·7, pantothenic acid 30·4 and vitamin B_{12} 56. This takes no account of distribution within the population. A special inquiry suggests that pregnant women, drinking between 400 and 700 ml. daily, have less

than the recommended amounts. Similar studies of schoolchildren have shown that consumption standardised to 8½ years of age is higher, 615 ml. daily, by the children of professional parents than by those of unskilled workers, 460 ml., and that there were parallel differences in height and weight. Milk in school did not affect consumption at home.—I. Leitch.

3573

VAN SYCKLE, C. **Consumption of fresh and evaporated milk and dry milk solids.** *J. Amer. Dietetic Assoc.*, 1955, **31,** 1228–1231. [Dept. Home Econ., State Coll. Washington, Pullman.]

In 226 households of 2 or more persons in Everett, Washington, the average weekly consumption of fresh milk, with evaporated milk and dry milk solids in terms of milk equivalent, was 12·5 qt. Children drank more fresh milk than young adults and young adults more than older adults.—F. C. Aitken.

FOOD ECONOMICS AND STATISTICS

3577

WADHAM, S. M. **The world food problem—technical or social?** *Med. J. Austral.*, 1953, i, 209–216. [Univ. Melbourne.]

The march of agriculture and the growth of population are compared throughout the world, with particular attention to Australian aspects of the problems.—E. M. Hume.

3578

SCHULZ, T. **A 'human needs' diet: autumn 1955.** *Bull. Inst. Statistics Oxford*, 1956, **18,** 87–93.

The cost of a "human needs" diet in the autumn of 1955 was 68s. 8½d. compared with 63s. in the spring (Abst. 967, Vol. 26), a rise of over 8 per cent., due mainly to the increased costs of bacon, other meat, eggs and cheese, and potatoes. Barley, rice and dried peas were cheaper, but there was a tendency to replace such foods by others requiring little or no cooking.

Subsidiary tables show the amounts of energy, protein, Ca and Fe, relative to bread as standard obtained from sixpenceworth of the foods listed, and the contributions of these foods to the nutrients and cost of the "human needs" diet. Bread and flour, both fortified with Ca, were the cheapest and best balanced foods, though cheese and milk provided more Ca and dried peas and lentils more protein for the money. As sources of animal protein, herrings, cheese and [condensed] skimmed milk cost about half of what meat did and a third of what eggs did.—W. M. Deans.

DIET IN ETIOLOGY OF DISEASE

METHODS OF ASSESSING STATE OF HEALTH

3579

BOLTON, J. H. **Food, the appearance of the tongue, and the appreciation of bone vibration.** *Med. J. Austral.*, 1955, i, 10–13. [Melbourne.]

Diet histories that were roughly quantitative were taken from 68 patients, aged from 18 to 78, examined during 4 years' private practice. None showed definite signs of organic disease apart from atherosclerosis in the older patients. The state of the tongue was classified, by appearance, into one of 6 grades described; the changes are regarded as very early signs of pellagra. Appreciation of bone vibration was measured by direct comparison between observer and patient, a fork of 256 vibrations per second being applied to the pad of the index finger. Six degrees of perception are described, and a mechanical vibrometer showed that grading for an individual remained reasonably constant.

Foods recorded in the diet histories were grouped as animal proteins, fruit, vegetables and foods containing B vitamins; for each group histories were classified as high, moderate and low. Analysis by multiple regression showed that only animal protein, particularly the daily intake of meat and eggs, significantly affected tongue grading, and foods rich in B vitamins, particularly cereals and yeast extract, were of importance in relation to perception of bone vibration. Age had a significant effect on both.

The value of tongue change as an index of nutritional state was shown by a multiple correlation coefficient of 0·64. Records of bone vibration were relatively consistent in the hands of a single observer and their value as a nutritional index was shown by a multiple correlation coefficient of 0·63.

GANDEVIA, B. and HOSSACK, D. **Tongue appearance and serum albumin level in the assessment of nutritional status, with reference to the effects of a protein-rich diet.** *Med. J. Austral.*, 1955, i, 344–346. [Royal Melbourne Hosp.]

Repeated estimations of "tongue grade" (Bolton, see preceding Abst.), of albumin and total protein in serum, and of Hb were made on 2 groups of clinically healthy students, whose intakes of protein were recorded, one of 24 students living at home, the other of 16 students living in institutions. The mean intake, in g. daily, of first-class protein was 63 for the first and about 46 for the second. Those living at home showed a significantly better tongue grade, 0·85 against 1·39, and a higher mean for serum albumin, 4·57 against 4·07 g. per cent. Values for Hb and total protein were not significantly different. After 2 weeks at home on a diet which was very rich in protein, those who had been in institutions gave values like those of students living at home.

Statistical analysis showed that tongue grade and serum albumin reflected the dietary protein intake of a group, and could be used to assess nutritional status in respect of protein. The influence of protein intake on blood volume and on values for serum albumin and Hb is discussed.

EISENMENGER, W. J. **Hepatic function and protein metabolism in cirrhosis of the liver.** *Med. Clins. N. Amer.*, 1955, **39**, 719–734. [Hosp. Rockefeller Inst. Med. Res., New York.]

GENERAL STUDIES

3582

MILLIS, J. **Gain in weight and length in the first year of life of Chinese infants born in Singapore in 1951. The influence of nutrition on the growth rate in the first year of life of Chinese infants born in Singapore in 1951.** *Med. J. Austral.*, 1954, i, 283–285; 322–327. [Dept. Social Med. Pub. Health, Univ. Malaya, Singapore.]

See also Absts. 2634, Vol. 25; 3544, Vol. 26.

(a) A representative group of 73 male and 55 female term, normal pure Chinese infants of families in the lower income groups in Singapore in 1951 was studied; 103 babies were still under observation on their first birthday.

Weight curves were constructed from 2055 measurements made every 2 weeks from birth to 12 weeks, and then every 4 weeks to one year of age. The curves for Chinese infants in Singapore were similar to those for Chinese infants in China (Gin, Abst. 2236, Vol. 18), and for the first 20 weeks of life they corresponded with those of white infants in America and Australia, but in the second half of the first year they were lower. At one year old, the average Chinese male infant was from 47 to 54 oz. and the average Chinese female infant from 54 to 60 oz. lighter than the corresponding white child.

The length of the babies was recorded, in 337 measurements at birth and at 24 and 52 weeks of age. The mean birth length of Chinese male babies was 19·3 in. and of females 19·0 in., both being less than those of white American babies. The proportional increase in length of Chinese and American babies in the first year was the same.

(b) Observations were made on 103 term, normal pure Chinese infants, 57 males and 46 females. They were divided into 4 groups according to the duration of breast feeding, less than 12 weeks, 12 to 32 weeks, 32 to 48 weeks, and longer than 48 weeks. Supplementary feeds were of sweetened condensed milk and powdered milk. At 24 weeks of age, 31 infants were receiving rice, cornflour or oatmeal, and after 24 weeks many were given meat and fish. Only 2 received vegetables at any time during the first year. Supplements of orange juice, cod liver oil and yeast extract were little used.

At one year old, 32 infants were receiving less than one pint of milk a day, and their diet was deficient in first-class protein, vitamin C and probably riboflavin. There was no clinical sign of scurvy, but there was some retardation of growth, low resistance to infections and slow healing of skin wounds in the second half of the first year.

The mean weight of each group at different ages was calculated. During the first 24 weeks, wholly or partly breast-fed babies increased in weight more rapidly than artificially-fed babies, but there was no correlation between gain in weight and duration of breast feeding, and there appeared to be no advantage to gain in weight from breast feeding after 28 weeks.

The infants were medically graded at one year old; 4 were very good, 21 good, 63 satisfactory and 15 poor. Infants breast fed for longer tended to be graded higher. The incidence of minor illnesses was small in the first 5 months, but increased rapidly.

All but 3 of the babies made satisfactory progress by generally accepted standards. Housing and hygiene were poor, but variations within a group did not seem to be reflected in the progress of the child.—M. H. Pierce.

3583

JANSSENS, P. G. Over de kleutersterfte in de arbeidersgezinnen van de Kilo-Moto goudmijnen. [**Death rate of toddlers among workers in the Kilo-Moto gold mines.**] De mortaliteitsoorzaken der schoolkindersterfte van de Klo-Moto mijnen. [**Causes of death among schoolchildren of the Kilo-Moto mines.**] *Ann. Soc. belg. Méd. trop.*, 1955, **35,** 151–171; 173–186. French summaries.

(a) A report is made on the causes of death found at autopsy between 1938 and 1943 in 679 child patients dying in the native hospital of Mongbwalu (Ituri), which serves the families of the workers in the Kilo-Moto gold mines. Of these, 544 were children from 13 months to 3 years of age, and 135 were aged from 3 years to 6 years. Pulmonary diseases were the cause of death in 60·1 per cent., malaria in 13·2 per cent. and nutritional diseases in only 2·1, the total number dying from the last being 14. Two children had typical kwashiorkor, but the malnutrition of the rest was non-specific. The state of nutrition and development of the children as a whole was good. Fatty infiltration of the liver was far too frequent to have been caused by protein deficiency.

(b) In continuation of the previous inquiry, autopsies on 162 children aged from 6 to 15 years are reported. Respiratory diseases contributed a lower, but still the largest, proportion of deaths, 22·8 per cent. Deaths from nutritional disease were 3 from kwashiorkor and 1 from cachexia. Those with kwashiorkor were aged 7·8 and 15 years, and fatty infiltration of the liver was extensive. It was present in many of the older children, as in the toddlers, and could not be of nutritional origin.

E. M. Hume.

ARAKAWA, T., SATO, Y., IZURUMACHI, A. and MORINAGA, C. **Studies on the nutrition of children in Hirosaki area. 23rd report. Hepatic enlargement of children with nutritional dystrophy.**

ARAWAKA, T., SATO, Y. and KAGAYA, A. **24th report. Hepatic enlargement of breast-fed infants and its relation to nutritional dystrophy of their mothers.**

SATO, Y. **25th report. Liver biopsy findings in children with nutritional dystrophy.** *Tohoku J. Exp. Med.*, 1955, **63,** 81–85; 87–91; 93–101. [Dept. Paediat., Sch. Med., Hirosaki Univ.]

23. In 1779 children between 6 and 12 years of age in 3 districts in the Hirosaki area records were made of palpable livers and of nutritional dystrophy. The numbers of boys were 428, 317 and 164 and the percentages with nutritional dystrophy 14·4, 47·6, 79·9 and with palpable livers 11·6, 20·8, 33·5. For girls the numbers were 410, 312 and 148 and corresponding percentages 4·8, 26·2, 67·5 and 4·6, 8·3, 27·7. The liver was palpable more often in dystrophic children than in the others.

24. The mothers of 50 infants who were exclusively breast fed and the palpability of whose livers was measured were examined for nutritional dystrophy; 24 were found to have the disease and 26 to be free from it. Riboflavin was estimated in their milk and mean values for these respective groups were $24{\cdot}6 \pm 3{\cdot}3$ and $32{\cdot}7 \pm 2{\cdot}7$ μg. per 100 ml. The 26 mothers without the disease were equally divided in respect of liver enlargement in their infants; of the 24 with the disease only 1 had an infant whose liver was not palpable. The riboflavin content of the mother's milk was not closely related either to the incidence or to the extent of the enlargement of the infant's liver.

25. The histological findings are tabulated for specimens obtained by biopsy from the livers of 30 children in all of whom signs of nutritional

dystrophy, such as angular stomatitis, cheilosis, swelling or atrophy of lingual papillae, and skin pigmentation, were present, whose livers were enlarged and in some of whom there were other complications. The commonest abnormalities, which appeared on the number of occasions indicated, were the plant-cell appearance as defined by Gillman and Gillman (" Perspectives in Human Malnutrition ", 1951, Grune and Stratton, New York) 22, diffuse fibrosis 12, basophilia of parenchyma 11, cloudy swelling 10, zonal necrosis 5 and fatty drops 5.—D. Harvey.

3585

CLEMENTS, F. W. **Some studies on the aetiology of knock-knees.** *Med. J. Austral.*, 1954, i, 737–741. [Inst. Child. Health, Univ. Sydney.]

Knock-knees are relatively common in Australia. The incidence of knock-knees and of Harrison's sulcus and the degree of dental caries in 100 children during the first 10 years of life showed no correlation *inter se*, or with the occurrence of rickets, proved by X-ray, in infancy.

The alignment of the bones in the knee joints of normal and knock-kneed children suggested that subnormal tensile strength of the anterior cruciate ligament is the main cause.

The histology of the cruciate ligaments was studied at different stages of development in the rat, guineapig, human foetus, newborn infant and young child. Nutritional experiments on young rats showed that a low-protein diet or artificially produced rickets did not affect the microscopic structure of the ligament. Acute and chronic scurvy in the guineapig did produce soft, easily broken cruciate ligaments which differed microscopically from those of normal animals. The reasons for such differences are discussed.

M. H. Pierce.

3586

GOODMAN, J. I. and DOWDELL, W. **The specter of malnutrition in chronic illness.** *Ann. Int. Med.*, 1955, **43**, 1241–1258. [Cleveland, Ohio.]

One hundred and thirty-eight from a series of 431 malnourished patients in a county home previously described (Goodman, *J. Amer. Med. Assoc.*, 1953, **152**, 1336) are reviewed in detail. Enlarged liver was found in 89 and in 85 was attributable to malnutrition. Forty subjects had no teeth and in 25 teeth were carious. Average red cell count was 3·95 million per c.mm. and Hb value 11·6 g. per 100 ml. Serum protein levels were within normal limits. The response to a high-energy diet was favourable in over half the patients. The causes of malnutrition were: poor food and eating habits, mental disorders, anorexia, low social status, carcinoma of oesophagus, intercurrent infection and inattention by attending staff to the patient's intake of food.—F. C. Aitken.

3587

TRÉMOLIÈRES, J., MOSSÉ, A., LYON, L., PASCHOUD, J. and DÉROBERT, L. Enquête sur le régime alimentaire cirrhogène chez l'homme. **[Study on cirrhosis-producing diet in man.]** *Bull. Inst. nat. Hyg., Paris*, 1955, **10**, 673–684.

Studies were made on 48 subjects with cirrhosis. Diet is taken as that recorded by 3 interviewers who checked methods against each other. Questions covered 5 years and, separately, the last 6 months before the first illness. Members of the families other than the patients were questioned also. Women are, in general, reluctant to admit addiction to alcohol; men urge the compulsion to be sociable as an excuse.

Estimates are presented for the approximate consumption of alcoholic drinks (vin, 10°), at table and total, by men and women separately, as in the average French family. The totals are for men and women, as calories from alcohol, per cent. of food calories: agricultural labourers 27·9 and 14·4; heavy workers 25·4 and 13·5; manual workers 23·1 and 9·1; other workers 15·8 and 9·3; professional 17·3 and 10·2. In comparison with these estimates, cirrhotics during the 5 years before breakdown ate less and drank the equivalent in calories of, on the average, 79 per cent. of food calories; during the last 6 months, they ate still less and drank relatively more, so that the calorie value of alcohol, on the average, exceeded that of food. The diet then resembled that of semi-starvation as induced by Keys. Metabolism studies were therefore made on 7 cirrhotics over 1 to 2 months with a rehabilitation diet. Retention of N was much more than in Keys's rehabilitation studies, 5 to 15 g. N in 24 hr. as compared with 3 to 6 g. It is suggested that alcohol in amounts equivalent to or exceeding the energy value of food, with a semi-starvation diet, inhibits the use of protein and that therefore omission of alcohol and return to normal diet means over-normal retention of N.—I. Leitch.

EPSTEIN, F. H., SIMPSON, R. and BOAS, E. P. **Relations between diet and atherosclerosis among a working population of different ethnic origins.** *Amer. J. Clin. Nutrit.*, 1956, **4**, 10 – 19. [Res. Dept., Sidney Hillman Health Centre, New York.]

Energy and fat intakes of 250 men and 164 women were estimated from diet histories. Mean age of the men was 57 and of the women 54. Most of the subjects were Italian or Jewish. Italians and Jews ate about the same amount of fat; the Jews tended to eat a higher proportion of animal fat. In men, but not in women, a fat intake of 40 per cent. or more of total calories was associated with a greater prevalence of atherosclerosis and

high blood cholesterol than was a fat intake of 30 per cent. or less of total calories. Overweight was not related to prevalence of atherosclerosis or high blood cholesterol in men or women. The frequency of atherosclerosis was about the same for Italians and Jews. Jewish men and women had higher incidences of high blood cholesterol than had Italians. In a larger group of men the incidence of coronary artery disease among Jews was twice that among Italians. The findings are discussed.—F. C. Aitken.

MICHAUX, L. and GEORGES-JANET, L. Un facteur d'anorexie mentale des adolescentes. La répudiation des soucis matériels, affirmation " d'intellectualisme pur ". [**A mental factor in anorexia in adolescents. Repudiation of material cares an affirmation of " pure intellectualism ".**] *Presse méd.*, 1956, **64,** 181–183. [Paris.]

Case histories are given of 5 young women aged from 17 to 20 with anorexia. None had ever had a good appetite, and in all the psychological background was similar. They had intellectual or artistic gifts and aspirations unshared by their poor or uneducated parents, and although they expressed gratitude and attachment, they repudiated their parents' interest in material things, such as food, and thus were in a state of perpetual conflict. Some were cured or improved by a change of environment.—W. M. Deans.

CAMBON, E. N. and CAMBON, K. G. **Health survey in a British Guiana mining community.** *Arch. Indust. Health*, 1955, **12,** 539–542. [Mackenzie Hosp., British Guiana.]

In all, 1730 native employees, mainly African in origin, of a bauxite mining and milling company in the interior of British Guiana were medically examined. The climate is hot and wet, with mean temperature 80° F. and annual rainfall about 100 in.

Over 95 per cent. had caries; whether it was due to diet or to lack of dental care is not known. Hb value was between 70 and 80 per cent. in 1207, but the average for women at the mothers' welfare clinic was only about 54 (7·83 g.). For native typists in the firm's office it was 64 (9·28 g.) and for native nurses 76 (11·08 g.). Whether the difference is due to better prevention of hookworm infestation, which is common, or to better diet is not known. Nine cases of diabetes were found; treatment is difficult since the local diet is chiefly of carbohydrate and high-protein foods are too dear for the average person.

The view is expressed that nutrition cannot be improved without a change in the general agricultural policy of the colony. There is a chronic shortage of meat, fish and green vegetables; much food is imported, even English potatoes, although rice can be grown on a fairly large scale.

BOYER, P. H. **Low birth weight in fibrocystic disease of the pancreas.** *Pediatrics*, 1955, **16,** 778–784. [Dept. Paediat., Coll. Phys. Surg., Columbia Univ., New York.] Interlingua summary.

The distribution of birthweight in a group of white infants, 75 girls and 98 boys, with fibrocystic disease of the pancreas, was compared with that of 1000 white infants of both sexes born from November 1948 to June 1950 in Sloane Hospital for Women, and the results are shown in tables and graphically. For each sex separately, mean birthweight and proportion of infants weighing over 3000 g. at birth were significantly less for the afflicted group. It is suggested that in this disease either the mother fails to supply some substance essential for the growth of the foetus, or the foetus, by reason of some inherited metabolic defect, is unable to utilise the nutrients supplied.

A preliminary report (Anderson and Boyer, paper in preparation) on 100 women who had already had an infant affected with the disease and who during a subsequent pregnancy had been instructed to take a diet rich in protein, minerals and vitamins, supplying from 2500 to 2800 Cal. daily, indicates that the birthweight was raised thereby, even where the infants again had fibrocystic disease of the pancreas. Whether the incidence of the disease can be reduced by better diet during pregnancy is not yet clear.—W. M. Deans.

MACK, H. C., KELLY, H. J. and MACY, I. G. **Complications of pregnancy and nutritional status. 1. Toxaemias of pregnancy.** *Amer. J. Obstet. Gynecol.*, 1956, **71,** 577–592 (with discussion 592–595). [Dept. Obstet. Gynaecol., Harper Hosp., Detroit, Mich.]

The subjects studied, more than 1000 white and Negro women, are stated not to be representative of any particular community or hospital group. Toxaemic were compared with normal patients, by month of pregnancy and by race, in terms of Hb and levels of protein, vitamins A and C, carotenoids and alkaline phosphatase in serum. The results did not support the view that malnutrition plays an important part in susceptibility to pre-eclampsia and eclampsia. Newer and better survey techniques are thought to be necessary. See also Abst. 5104, Vol. 24.—A. M. Thomson.

3596

BELL, M. E. and WILLS, L. **Racial differences in incidence of pre-eclampsia and eclampsia in Fiji.** *J. Obstet. Gynaecol. Brit. Empire*, 1955, **62,** 917–921. [Dept. Nutrit. Res., Univ. Otago Med. Sch., Dunedin, N.Z.]

A review of hospital records for 1947–50 in Suva confirmed the authors' finding that pre-eclampsia and eclampsia are rare in Fijian but relatively common in Indian women (*Fiji Med. Dept. Annual Rep.*, 1950 (Government Press, Suva)). Theories which account for the difference in terms of diet are briefly reviewed. It is concluded that more information is needed, since the ways of life of the two races differ in many respects.—A. M. Thomson.

ANDRÉ, J. and HOLEMANS, K. Mortinatalité et mortalité néonatale des 10 premiers jours en secteur Foréami (Kwango, Congo Belge). [**Stillbirths and neonatal mortality in the first 10 days in the Foréami district (Kwango, Belgian Congo).**] *Ann. Soc. belg. Méd. trop.*, 1955, **35,** 661–671. [Léopoldville.] Flemish summary.

In a rural district where the traditional African mode of life still persisted, 7·19 per cent. of the 5732 infants born in 1954 were premature with a birthweight under 2 kg.; 21·58 per cent. were classed as debilitated and had a birthweight between 2 and 2·5 kg., and 71·23 per cent. were normal with a birthweight above 2·5 kg. The total stillbirth and neonatal death rate during the first 10 days of life was 75·54 per 1000 live births. Most of the deaths were among the premature and debilitated infants, especially the boys. The figures agree broadly with those from the relatively wealthy mine area of Kilo-Moto. Obstetrical difficulties cause fewer stillbirths among Africans than among Europeans; prematurity and debility, both regarded as connected with chronic malnutrition, are the chief cause of stillbirth. The syphilis rate is low. All the mothers had chronic malaria but malaria in infants is not considered to be a cause of early death.—L. Wills.

BURGIO, G. R. and GIACALONE, O. Ricerche elettroforetiche sul siero di sangue in alcuni stati distrofico-carenziali dell'infanzia. 1. Casistica. Quadri sieroproteici. [**Electrophoretic investigation of the blood serum in certain states of deficiency and malnutrition in childhood. 1. Case histories. Picture of the serum proteins.**] *Pediatria*, 1955, **63,** 630 – 667. [Clin. Pediat., Univ. Palermo.] French, English, German and Spanish summaries.

Total protein was estimated, and a full analysis of the protein fractions was made by electrophoresis with the apparatus of Tiselius, in the blood of 22 normal babies up to 2 years old, 20 infants with non-specific malnutrition, 22 children with specific deficiencies chiefly of riboflavin, or with kwashiorkor, and 12 infants with "pernicious anaemia of infancy".

In the group with non-specific malnutrition, mean values for total proteins were normal or slightly low. The α_1- and α_2-globulin fractions

were high. Albumin and γ-globulin were slightly low.

The group with kwashiorkor or other deficiency was not homogeneous. Total proteins were always low. Mean values for albumin and α_2-globulin were low; α_1-globulin was high and γ-globulin was normal or somewhat high.

Some of the infants with "pernicious anaemia" had signs of other deficiencies, but if the anaemia was uncomplicated the mean plasma values were within the normal range or slightly low.

E. M. Hume.

3602

WENT, L. N. and GANDASOEBRATA, R. R. **Some investigations into the blood chemistry of kwashiorkor.** *Doc. Med. geogr. trop.*, 1955, **7,** 363–370. [Dept. Biochem., Fac. Med., Univ. Indonesia, Djakarta.]

In a series of 58 infants aged from 9 months to 4 years, whose nutritional state varied from "normal" to that associated with frank kwashiorkor, the total serum protein value was lower the poorer the nutritional state. The mean value for the "normal" was 7·0 g. per 100 ml. and for the patients with kwashiorkor 4·1 g. per 100 ml. The mean albumin: globulin ratio was 1·1 for the "normals" and 0·5 for the remainder. The mean γ-globulin value for "normal" and malnourished children ranged from 1·6 to 1·8 g. per 100 ml.—L. Wills.

GOPALAN, C. **Kwashiorkor in Uganda and Coonoor. (A comparison of some salient aspects.)** *J. Trop. Pediat.*, 1955, **1,** 206–219. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor.]

In an interesting general article it is made clear that in all important respects kwashiorkor is similar in India and Africa. The small differences reported result from local differences in mode of life, diet, incidence of infection and infestation and possibly, in the hair changes, from race.—L. Wills.

3604

GEBER, M. and DEAN, R. F. A. **The physiological changes accompanying kwashiorkor.** *Courrier*, 1956, **6,** 3–15. [Med. Res. Counc., Group Res. Infantile Malnutrit., Mulago Hosp., Kampala, Uganda.] French and Spanish summaries.

In a study of the effects of treatment of kwashiorkor (see Abst. 2193, Vol. 23) on the signs of irritability and petulance which often accompany the disease, 25 successive children, admitted to hospital for treatment, were tested on arrival and again after treatment for 1 and 4 weeks. The Gesell tests which were applied and which are intended to measure psychomotor development are briefly described. The results of the psychological tests agreed with those of biochemical tests in the acute stages, mental outlook being affected to the greatest extent in those in whom blood chemistry was most abnormal. During recovery this agreement did not persist in all.

In hospital mothers were allowed to stay in close association with their children, but the extent of interest shown in the welfare of a child varied greatly. The child's rate of recovery seemed to be influenced by the relationship of mother to child. Where this was good recovery tended to be rapid and complete; where it was bad the unsatisfactory psychological conditions were likely to persist after physical recovery. The implications of the African child's mode of early life and of the tribal custom of sending it at an early age, often at weaning, to live with a relative are discussed.—D. Harvey.

3605

SAID, M. **Kwashiorkor in Negri Sembilan.** *Med. J. Malaya*, 1955, **10,** 20–47. [Maternity Ward, Gen. Hosp., Seremban.]

The first half of this paper gives details of the histories of 9 children, 6 Malay and 3 Tamil, between $1\frac{1}{2}$ and 5 years of age who were admitted to hospital and of whom 2 of the Tamils died. In the second half these clinical findings are discussed in relation to descriptions of the disease as it occurs in Africa (Brock and Autret, p. 278, Vol. 22), in Indonesia (see Absts. 2304, 3608, Vol. 24) and in Fiji (see Abst. 818, Vol. 23).

For all 6 Malay children it was the appearance of blindness or kerotomalacia and not malnutrition that was the reason for their being brought to hospital. The occurrence of abnormally long eyelashes, as reported from Indonesia, was confirmed. Treatment was with skimmed milk powder and Casilan and, except in the 2 who died and in whom dehydration was severe, diarrhoea and skin disorders soon abated. Since eyesight was affected in all the Malay patients it is thought possible that many others with kwashiorkor but without eye lesions may remain undetected, and pleas are put forward for surveys to be made in villages and on rubber estates and for the inclusion of the elements of nutrition in the syllabus of education of pupil midwives.—D. Harvey.

ANDRÉ, J. and HOLEMANS, K. Signification des cheveux roux chez le nourrisson noir du Kwango. [**Significance of reddish hair in the negro infant of the Kwango.**] *Ann. Soc. belg. Méd. trop.*, 1955, **35,** 467–477. Flemish summary.

Of 642 representative infants aged up to 3 years, 368 or 57·3 per cent. had hair changes; the incidence was highest between the ages of 6 and 12 months. Protein balance studies showed that a protein deficit, which was present from birth, increased to a maximum of 8·5 g. daily between 6 and 12 months. The incidence of kwashiorkor reached its maximum 9 months after the time of maximum incidence of red hair, suggesting that the hair changes are an early sign of protein deficiency. The infants with red hair had significantly lower weights than those of the same age with black hair. The incidence of infestation, chiefly with ascaris, in all the children was 60·74 per cent.; it was at a maximum between the ages of 2 and 3 years. From a statistical analysis of the incidence of red hair among the infants with and without infestation it was impossible to exclude infestation as a cause of red hair in the age group from 6 to 12 months, but it could be excluded in the age group from 2 to 3 years. From these contradictory results it is concluded that infestation increases the demand for protein and thereby favours the development of red hair, particularly in the critical period between 6 and 12 months. The conclusion is confirmed by the rarity of red hair in the infants of the well fed urban population of Léopoldville although the infestation rate is similar to that among the rural children. The incidence of red hair is considered as a useful index to the nutritional state of a population.—L. Wills.

DAKSHINAMURTI, K. and DEVADATTA, S. C. **Studies on the nutrition of urban population groups.** *Proc. Indian Acad. Sci.* [*B*], 1956, **43,** 121–133. [Christian Med. Coll., Vellore.]

Seven-day diet studies were made of 507 families living in an area noted for high incidence of cirrhosis of the liver. The results in terms of quantities of foods and nutrients are tabulated per consumption unit per day. Intakes of energy, protein and fat were low and the diets were generally poor in quality as well as quantity. Sample diets were analysed for amino-acid content. The data are tabulated and discussed in relation to the etiology of liver injury.—F. C. Aitken.

3612

LUYKEN, R. and LUYKEN-KONING, F. W. M. **Nutritional state of the Marind-Anim tribe in South New Guinea.** *Doc. Med. geogr. trop.*, 1955, **7,** 315–339. [Centr. Inst. Nutrit. Res. T.N.O., Utrecht.]

The nutritional status of the tribe was determined from body measurements, an assessment of the nutritional condition and the presence of clinical signs of deficiency. The results showed that in infants the weight and growth curves flattened at weaning, that in general adults and children were better nourished on the coast than inland, and that the most frequent deficiencies were of vitamin A, vitamin B_1 and protein. The staple food was sago. The meat supply, which depended entirely on hunting, and the fish supply were irregular and both were reduced during the wet season.—L. Wills.

3613

MCCARTHY, D. D. **Liver enlargement and protein deficiency states in Polynesians in Western Samoa, Niue and New Zealand.** *N.Z. Med. J.*, 1955, **54,** 651–657. [Island Territories Res., Med. Sch., Otago.]

The percentage with enlargement of the liver at all ages up to 20 years was 11·9 in Samoa, 7·07 in Niue and 0·97 for Maoris in New Zealand; for children between the age of 1 and 4 years the corresponding figures were 18·4, 15·8 and 7·2. The incidence among boys was greater than among girls. None of the children showed any sign of kwashiorkor, and gross malnutrition was uncommon though many children were undernourished. Starchy foods predominated in the diet of both Samoans and Niueans and probably in the diets of infants among the Maoris. The findings and the presence of gynaecomastia in adult males and that of cirrhosis of the liver in the older age groups in both sexes in Samoa are taken as evidence of protein deficiency in Polynesian diets.

Vitamin A

3615
PEIRCE, A. W. **Carotene and vitamin A in human fat.** *Med. J. Austral.*, 1954, i, 589. [Div. Biochem., C.S.I.R.O., Univ. Adelaide.]

Two highly coloured specimens of human fat were extracted with acetone and light petroleum, and β-carotene and vitamin A were separated chromatographically and estimated by spectrophotometry. The values obtained in μg. per g. fat for the 2 samples were β-carotene 6·1 and 5·1, and vitamin A 2·2 and 2·0; they were of the same order as the highest previously reported in the literature. The percentage of the total pigments that represented β-carotene was 47 and 38.

Subcutaneous connective tissue from an emaciated subject, containing little fat but patches of yellow pigment, was extracted also, and the spectral transmission curve corresponded closely with that of carotene.

It is concluded that carotene is removed with difficulty from subcutaneous fat deposits, and that carotene which escapes conversion to vitamin A in the wall of the small intestine is probably lost to the body thereafter.—M. H. Pierce.

3616
CLELAND, J. B. **The colour of human fat.** *Med. J. Austral.*, 1954, i, 588. [Dept. Pathol., Univ. Adelaide.]

At autopsy the colour of the fat in 20 bodies, 12 males aged from 14 to 81, and 8 females aged from 22 to 75, was classified according to Ridgway's "Color Standards and Color Nomenclature" (Washington, 1912). Twelve colours were recorded, ranging from deep chrome to primuline yellow.

It is noted that the fat of babies is very pale in colour, but that age, sex and the condition causing death appear to bear no relation to the colour of the fat. The possible relation to diet and the fate in the body of carotenoids associated with fat are discussed.—M. H. Pierce.

3617
RIECHERT, W. Der Vitamin-A-Gehalt des Blutes vor und nach Belastungen mit Vitamin A. [**Vitamin A content of the blood before and after test doses of vitamin A.**] *Deutsch. med. Wochenschr.*, 1956, **81,** 38–39. [Med.-Diagnost. Inst., Städt. Krankenanst., Karlsruhe.]

Of 150 healthy subjects, the percentage having values per 100 ml. plasma of from 100 to 150 I.U. was 17, from 150 to 200 I.U. it was 38·5, and from 200 to 250 I.U. it was 29. A single dose of 150,000 I.U. vitamin A as an aqueous emulsion (Arovit) raised the blood value, with the peak after from 3 to 4 hr. Return to the initial value was complete after from 8 to 10 hr. The maximum value attained varied greatly between individuals. When the same test was made after daily administration of 150,000 I.U. for 14 days, no consistent relationship was found between the history of past intake and the magnitude of the peak caused by the test dose.—T. Moore.

3618
GOUNELLE, H. and BLONDIN, M. Le retentissement des états colitiques sur la nutrition mis en lumière par l'épreuve d'hypervitaminémie A. [**The effect of colitis on nutrition as shown by the high-blood-vitamin-A test.**] *Arch. Mal. Appar. digest.*, 1955, **44,** 661–665 (with discussion 665). [Centre Recherches Foch, Inst. Nat. Hyg.]

The fasting value for vitamin A was estimated by the Carr Price method in the blood plasma of 14 patients with colitis of different types, and of 12 normal subjects, before and 3 and 6 hr. after oral administration of 500,000 I.U. vitamin A. For the normal subjects and patients, respectively, the mean values in I.U. vitamin A per 100 ml. plasma were before the test dose 129 with range 39 to 266, and 88 with range 14 to 231, and 6 hr. after it 807 with range 556 to 1263, and 235 with range 57 to 400. It is concluded that in colitis absorption of the vitamin is impaired, and that the other fat-soluble vitamins, D, E and K, and lipids in general are likely to be affected in the same way, so that a state of multiple deficiency may arise as a complication in colitis.—E. M. Hume.

3619
KRAUSE, R. F. and SANDERS, P. L. **The distribution of vitamin A in cells of normal and pathologic human livers.** *Amer. J. Clin. Nutrit.*, 1956, **4,** 68–70. [Dept. Biochem., Sch. Med., Univ. W. Virginia, Morgantown.]

Total vitamin A, vitamin A esters and vitamin A alcohol were estimated in the nuclei, mitochondria and residual cytoplasm, called fraction **x**, from samples of liver taken at autopsy from 7 human adults and 4 infants. Most of the subjects

had been ill, but only 4 had abnormal livers. The reserves ranged from 13 to 395 I.U. total vitamin A per g. Higher concentrations of vitamin A, and higher proportions of the free alcohol, were found in normal than in diseased liver, but disease had no effect on the proportions of the total found in the several cell fractions.—T. Moore.

EHRENGUT, W. Akuter benigner Hydrocephalus durch Hypervitaminosis-A (Syndrom Marie-Sée) bei Keratomalacie. [**Acute, benign hydrocephalus from excess of vitamin A (syndrome of Marie and Sée in a patient with keratomalacia).**] *Ztschr. Kinderheilk.*, 1955, **77**, 468–482. [Kinderpoliklin., Univ. Munich.]

Severe keratomalacia developed in a full-term, artificially fed infant, 4½ months old, that had suffered from severe skin infections. The infant was given in 2 days 5 mg. vitamin D and about 187,000 I.U. vitamin A; 2 days later the child showed fever, opisthotonus and swelling of the anterior fontanelle associated with somnolence, high pressure of cerebrospinal fluid, petechiae and rhinitis, typical signs of acute vitamin A excess (see Title 4984, Vol. 23). Withdrawal of vitamin A gave immediate improvement, but relapse occurred 2 days later when 44,000 I.U. vitamin A were given. Withdrawal of the vitamin again gave improvement. After 17 days vitamin A in small doses was given and the keratomalacia healed. The literature is briefly reviewed.

Vitamin D

3622

BERGER, H. and STALDER, G. Zur Frage der Aminoacidurie bei der Vitamin-D-Mangelrachitis der Säuglinge. [**Amino acids in the urine of infants with rickets due to deficiency of vitamin D.**] *Ann. paediat.*, 1956, **186**, 163–175. [Kinderklin, Univ. Basle.] English and French summaries.

Glomerular filtration with the help of inulin clearance tests, tubular re-absorption, and urinary excretion, of amino N were estimated in 3 healthy infants and in 5 with rickets, before and after a single dose of 15 mg. vitamin D_2 (Hydrosol, Wander) given by intravenous or intramuscular injection.

In the children with untreated rickets the amount of amino acids in the urine was from 2 to 5 times that in the normal children, and in 4 out of 5 of them the glomerular filtration of amino N was greater than it was after treatment. In normal children or after treatment of rickets tubular re-absorption was from 98 to 99 per cent., but in rickets before treatment it was from 91·4 to 96·4 per cent. The increased excretion is attributed to the decrease in tubular re-absorption. Improvement did not begin immediately after treatment and took some time to complete.

Chromatographic analysis of the amino acids in the urine showed that in rickets the amounts of serine, glutamic acid, glycine, alanine, lysine, threonine, arginine, tyrosine, proline, ornithine and asparagine were increased.—E. M. Hume.

HOTTA, T., MOTOTSUNE, H. and NAKANO, Y. **On the hepatic rickets.** *Yonago Acta med.*, 1955, **1**, 181–186. [Dept. Paediat., Tottori Univ. Sch. Med., Yonago.]

An infant 2½ months old was admitted to hospital with jaundice. Liver function was disturbed and the diagnosis made was congenital partial stenosis of the bile duct. In the course of examination rickets was found and was diagnosed as hepatic rickets. Chocola D, 20,000 "units" daily, was given orally for 10 days, but the low serum P value did not rise; with 100,000 "units" daily by intramuscular injection the value had risen after 10 days and rose further after 20 days. With ultra-violet irradiation for 10 days it rose further, and with ultraviolet irradiation and 100,000 "units" daily it had reached 6·23 mg. per 100 ml. after 10 days. Healing was then apparent radiographically. Liver function improved at the same time.—E. M. Hume.

3626

GALBRAITH, D. **Vitamin D resistant rickets.** *Med. J. Austral.*, 1953, ii, 208–210. [Melbourne.]

The causes of rickets resistant to vitamin D are briefly summarised and the case of a girl aged 10 years is described. The blood showed a raised content of inorganic P, urea and phosphatase, and a low alkali reserve. For 2½ years 50,000 "units" vitamin D_2 were given daily with little improvement, but when alkali treatment with

sodium citrate and citric acid was added, healing began; after 6 months it was almost complete at the wrists, and the teeth, which were absent, began to appear. The diagnosis was made of renal glomerular rickets but, since alkali treatment promoted healing, it is considered that there must have been pathological changes in the renal tubules also.

E. M. Hume.

3627

HAUGE, B. N. **Vitamin D resistant osteomalacia.** *Acta med. scand.*, 1956, **153,** 271–282. [Med. Dept., Drammen Hosp., Norway.]

After a short review of the subject, a case is described of a woman under observation for 17 years until she died at the age of 55 years from a malignant neurinoma in the left axilla. The patient was fully investigated in life and at post-mortem examination.

Calcium balance experiments with and without additions of Ca, P, vitamin D_2, stilboestrol, deoxycorticosterone and testosterone showed that the patient was in negative Ca balance with loss of about 200 mg. Ca daily. Some of the additions, particularly of vitamin D, brought her into positive balance with increased loss of Ca in the urine, but without improvement in clinical condition. In the course of years she must have lost about 1 kg. Ca, which would represent most of the Ca in the skeleton, so that rehabilitation would take correspondingly long. The results of the balance tests suggested that treatment with vitamin D, Ca and P might have brought her into continuous positive balance, but she died before treatment was instituted. The condition is identified as Milkman's syndrome.

No connection was demonstrated between the skeletal condition and the malignant neurinoma, but association of such a skeletal condition with neurofibromatosis has been reported.

HAMPERL, H. and WEISS, P. Über die spongiöse Hyperostosis an Schädeln aus Alt-Peru. **[Spongy hyperostosis in skulls from ancient Peru.]** *Virchows Arch.*, 1955, **327,** 629–642. [Pathol. Inst., Univ. Bonn.]

The porous outgrowths of bone on 3 skulls with only partly fused sutures, found in the coastal region of Peru, and dating back at least 500 years, are described in detail, with X-ray and histological illustrations, and are discussed with reference to the so-called osteoporosis described by others. The evidence suggests that they are not due to rickets, but to increased demands on the red bone marrow arising from haemolytic anaemia, possibly of the Cooley type. The resemblance to a change in the cranial bones found in severe rickets suggested that that too might arise from the anaemia which often accompanies severe rickets.—W. M. Deans.

WINBERG, J. and ZETTERSTRÖM, R. **Cortisone treatment in vitamin D intoxication.** *Acta paediat.*, 1956, **45,** 96–101. [Paediat. Clin., Karolinska Sjukhuset, Stockholm.] French, German and Spanish summaries.

A girl 11 months old was admitted to hospital with the ordinary signs of vitamin D intoxication after having received a total of 8 million "units" in 5 months. Serum Ca was between 15 and 16 mg. per 100 ml. Cortisone was given every 6 hr. for 2 periods of 4 days, with 3 days' interval. The patient immediately showed signs of improvement. Serum Ca fell to normal and serum citrate rose.

Vitamin E

3632

BURLINA, A. and PANIZZA, G. Vitamina E and lattazione. **[Vitamin E and lactation.]** *Lattante*, 1955, **26,** 706–714. [Div. Med., Osp. Civile, Oderzo.] English summary.

Ten women whose milk yield was inadequate 3 or 4 weeks after delivery were given 2 intramuscular injections of α-tocopheryl acetate daily for 20 days. Yield was measured for 3 days before treatment and for 3 days at the end of it. Before treatment the daily yield ranged from 200 to 305 ml. and after it from 495 to 590. The dry matter of the milk was increased, the fat being most affected. Tests to ascertain indirectly any effect of vitamin E on pituitary function gave negative results; the B.M.R., the blood sugar curve in response to administration of glucose, Thorn's test, and the 17-ketosteroids content of the urine were all unchanged.—E. M. Hume.

3633

GORDON, H. H., NITOWSKY, H. M. and CORNBLATH, M. **Studies of tocopherol deficiency in infants and children. 1. Hemolysis of erythrocytes in hydrogen peroxide.** *Amer. J. Dis. Child.*, 1955, **90,** 669–681. [Sinai Hosp., Baltimore.]

Suspensions of 2·5 per cent. erythrocytes in a saline-buffer mixture were incubated for 15 min. at 37° C. The erythrocytes were then re-suspended in 0·9 per cent. saline to make a 5 per cent. suspension and incubated at 37° C. with 2·4 per cent. H_2O_2 for 15 min. The suspension was centrifuged and the colour of the supernatant fluid, estimated in a photo-electric absorptiometer, was used as a measure of haemolysis.

The test was applied to the erythrocytes from 282 full-term and 67 premature newborn infants unfed. More than 50 per cent. haemolysis was found in from 25 to 48 per cent. and from 31 to 56 per cent. of these groups; the difference between them was not significant.

Thriving full-term infants fed on cow's milk showed less haemolysis at an average age of 7 weeks than at birth; the average percentage haemolysis was for 29 white babies 43 at birth and 21 after 7 weeks, and for 25 negro infants 49 at birth and 31 after 7 weeks. Other infants of the same age which had been breast fed showed still less haemolysis, 4 per cent. for 7 white and 11 per cent. for 11 negro infants.

Observations were made also on 17 full-term infants admitted to hospital for acute febrile and non-febrile illnesses. Twelve of them, all of whom had been given diets low in fat, showed over 50 per cent. haemolysis. When *dl*-α-tocopheryl acetate was given by mouth to 23 premature and 8 full-term babies, in every one there was a prompt decrease in the percentage haemolysis, even with daily doses as small as 1 mg. per kg. bodyweight.

Further 38 observations were made on 20 malnourished infants and children with steatorrhoea, and in 30 of the observations there was over 50 per cent. haemolysis, which could be corrected by giving large amounts of tocopheryl acetate, up to 300 mg. daily, but in infants with biliary atresia improvement was particularly difficult. Of 21 observations on malnourished infants and children without steatorrhoea only 2 showed more than 50 per cent. haemolysis. Other subjects investigated included infants and children with a variety of rare diseases, but none of them showed more than 4 per cent. haemolysis. The desirability of supplementing the diets of artificially fed infants with tocopherol is discussed.—I. M. Sharman.

3634

PROSPERI, P. Vitamina E ed emocoagulazione. **[Vitamin E and coagulation of the blood.]** *Riv. Clin. pediat.*, 1955, **56**, 532–539. [Ist. Clin. Pediat., Univ. Florence.]

After a review of the subject [no bibliography] in relation to human beings, brief reference is made to the author's success in treating several haemophiliacs with vitamin E. The effect being especially to shorten the coagulation time, the usefulness of the vitamin in emergencies is stressed. Favourable results are recorded also in other haemorrhagic diseases.—E. M. Hume.

3635

BURLINA, A. Azione dell'alfa-tocoferolo sul tasso ematico di glutatione. **[Effect of α-tocopherol on the values for glutathione in the blood.]** *Acta vitaminol.*, 1955, **9**, 246–248. [Div. Med., Osp. Civile, Oderzo.] French, English, German and Spanish summaries.

Of 12 normal adults, groups of 3 were given by mouth a daily dose of 100, 200 or 2000 mg. α-tocopherol, or none. Oxidised and reduced glutathione were estimated by the method of Binet and Weller in the blood before and after 1, 2, 3, 6 and 9 days of treatment, and again 3 days after treatment had ceased. There was no effect at all of giving tocopherol.—E. M. Hume.

3636

SHUTE, W. E. **Congenital heart disease treated with alpha tocopherol.** *The Summary*, 1955, **7**, 52–58. [Shute Inst., London, Ont.]

The value of treatment with α-tocopherol, usually 300 I.U. daily for prolonged periods, was studied in 35 patients with congenital heart disease. Their ages ranged from 14 months to 53 years. The tocopherol was effective in counteracting anoxia and relieving cyanosis and dyspnoea. Twelve patients were rendered symptom-free by the treatment and 22 were improved. A 3 to 6 months' course of tocopherol is recommended as a preparation for surgical treatment.—T. Moore.

3637

SCHMIDT, L. **Seven years' clinical experience in the treatment of rheumatic and ischaemic heart disease by vitamin E.** *The Summary*, 1955, **7**, 64–69. [Central Coal Board, London.]

Good results are claimed from treatment of 347 patients with rheumatic heart disease, 68 with coronary heart disease and 93 with angina pectoris by massive doses of tocopherol for prolonged periods. One illustrative case, in which the patient had been under observation for several years, is described for each of the conditions.

T. Moore.

3638

O'CONNOR, V. R. and HODGES, J. P. S. **Medical cases of cardiovascular and renal diseases treated with high doses of alpha tocopherol.** *The Summary*, 1956, **8**, 24–27. [Leamington Spa, Warwickshire.]

During 8 months 180 patients were treated with liberal doses of α-tocopherol. Except for deaths from other causes, such as cancer, no failure was recorded in the treatment of 12 cases of generalised

arteriosclerosis, 11 of acute peripheral thrombosis, 12 of acute cerebral thrombosis, 1 of cerebral vascular sclerosis, 3 of acute nephritis, 39 of hypertension, 48 of myocardial failure, 1 of heart block, 2 of acute rheumatic fever, 12 of chronic rheumatic heart disease and 2 of congenital heart disease. There was also no failure in the treatment of angina pectoris, of which the number of cases is not stated. One failure was admitted out of 3 cases of chronic renal failure, and 2 failures out of 35 of coronary thrombosis. Tocopherol appeared to be harmful in the treatment of patients with hyperthyroidism.

T. Moore.

3639

SHUTE, E. **Alpha tocopherol for pruritus ani.** *The Summary*, 1955, **7**, 15–16.

Of 23 patients who suffered from *pruritus ani* 12 were cured by treatment with from 400 to 600 I.U. α-tocopherol daily by mouth. The same treatment helped 9 other patients, but was unsuccessful in the remaining 2.—T. Moore.

HUNTER, R. A., MERIVALE, W. H. H. and SMITH, A. J. **Disturbances of carbohydrate metabolism caused by barbiturates and alcohol.** *Lancet*, 1955, **269**, 1353–1355. [Guy's Hosp., London.]

In 16 patients who had taken barbiturate for from 2 weeks to 108 months and who underwent the double glucose tolerance test, blood sugar values after 60 and 90 min. were higher, probably significantly higher, than in 16 normal subjects given the same test. Results were high also in a group of 5 alcoholic subjects. Blood pyruvate values after 60 and 90 min. also were high in both abnormal groups compared with those of 5 normal subjects and with the usual value reported in the literature. Daily injection of 20 mg. vitamin B_1 for 14 days improved or restored to normal the pyruvate metabolism in 5 patients who still took barbiturate and in 4 alcoholics deprived of alcohol during treatment. The effect of the vitamin on the blood sugar values varied. Abnormal electroencephalograms improved in 4 of the 5 barbiturate addicts treated with vitamin B_1.—L. Wills.

3642

LICHTENBELT, H. v. M. and FLORIJN, E. De behandeling van coma diabeticum met thiamine-pyrofosfaat. [**Treatment of diabetic coma with thiamine pyrophosphate.**] *Nederland. Tijdschr. Geneesk.*, 1956, **100**, 635–642. [Geneesk. Klin., Univ. Utrecht.] English summary.

3643

KOSAKA, K. **A study on the vitamin B_1 metabolism of the patients who received the gynecological laparotomy.** *Acta med. biol.*, 1955, **3**, 151–157. [Dept. Obstet. Gynaecol., Sch. Med., Niigata Univ., Niigata.]

Groups of patients undergoing laparotomy were given 3, 5 or 20 mg. vitamin B_1 daily by injection before and after operation; other subjects had no injection. Values for the amount in the urine and the concentration in the blood until the tenth day after operation are tabulated.

In the untreated patients excretion fell from 258 μg. before to, in general, below 50 μg. after operation; with 3 mg. daily the fall was less and by the fifth day the amount was back to that before operation; with 5 mg. there was little change. The variations in the concentration in the blood were similar, the values being lowest between the third and seventh days in the untreated group, with no change in the group having 5 mg.

ATKINSON, M. **The migraine syndrome.** *Practitioner*, 1956, **176,** 171–178. [Dept. Otolaryngol., Univ. New York.]

Very considerable relief of symptoms, in some patients amounting to complete suppression of headache for up to 6 years, was obtained in 26 cases of true migraine by treatment with enormous doses of nicotinic acid and nicotinamide, riboflavin and vitamin B_1 given at first both parenterally and by mouth and later by mouth alone for months or years. Maximum relief was obtained often only after months of treatment.—L. Wills.

3649

RALLI, E. P., KUHL, W. J. (Jr.), GERSHBERG, H., BECK, E. M., STREET, E. R. and LAKEN, B. **Effects of vitamin supplementation of the diet on reaction to short-term cold stress in normal young male adults.** *Metabolism*, 1956, **5,** 170–196. [Dept. Med., Coll. Med., New York Univ.-Bellevue Med. Centre.]

Four groups each of 12 normal well fed men were used in the trials. Stress was produced by immersion in water at 9·3° C. for 8 min. Each subject served as his own control, being subjected to stress before and after 6 weeks' treatment with daily supplements given by mouth. The different groups received, respectively, a dummy supplement, 10 g. Ca pantothenate, 12 μg. vitamin B_{12}, or the whole vitamin B complex with ascorbic acid. The response to stress and the effect of the supplements were judged by change in body temperature, pulse and blood pressure, in total and differential white cell counts, in serum Na, plasma K, serum total protein and water, in blood sugar, in lactic acid, ascorbic acid and total cholesterol in the blood, and in the urinary excretion of Na, K, Cl, ascorbic acid, uric acid and creatinine for up to 4 hr. after immersion. The findings are reported in detail.

In general the men had recovered completely in 4 hr. and there was no great difference in the responses obtained after the different supplements, but vitamin B_{12} decreased the mean fall of temperature after immersion. The one underweight subject who took part in the trials was on a diet of consistently low energy value with reduction of all the major components ; he had a severe reaction to the stress both beforehand and after treatment with the vitamin B complex and ascorbic acid.

BIANCHI DONNASIBILLA, L. and OLIVI, O. Potere desaminante e vitamine del gruppo B nel bambino. 4. Azione dell'amide nicotinica. **[Deaminating power and vitamins of the B group in children. 4. Action of nicotinamide.]** *Acta vitaminol.*, 1955, **9,** 249–252. [Clin. Pediat., Univ. Pavia.] French, English, German and Spanish summaries.

For previous parts see Absts. 1186, 2843, Vol. 22.

Amino N was estimated in the blood of 10 children, aged from 6 to 12 years, before, and 15, 30 and 60 min. after, intravenous injection of 15 mg. glycine per kg. bodyweight. The test was made before and at the end of intramuscular treatment with 20 mg. nicotinamide daily for 5 days. After 30 min. the mean value for amino N had fallen whether nicotinamide was given or not. After 60 min. it had fallen still further when nicotinamide was given, but had risen above the initial value when it was not given.—E. M. Hume.

3652

CORSINI, F. Osservazioni sull'eliminazione della vitamina B_2 nell'immaturo. **[Excretion of vitamin B_2 in the premature infant.]** *Boll. Soc. ital. Biol. sper.*, 1955, **31,** 576–578. [Ist. Clin. Pediat., Univ. Bologna.]

Riboflavin was estimated in the urine of 4 premature infants from 16 to 39 days old and of 3

full-term infants from 25 days to 5 months old. The amount, in μg. excreted in 24 hr., ranged from 30 to 300 for the premature and from 142 to 330 for the full-term babies, but the amount excreted by the same infant on different days varied widely, 206 and 111, for instance, for a premature infant, and 142 and 290 for a full-term one.

HIRASHIMA, H. **[Studies on angular stomatitis in Tokushima prefecture. 1. Angular stomatitis in children under 5 years of age.]** *Shikoku Acta Med.*, 1955, **7**, No. 5, 9–13. In Japanese: English summary. [Dept. Paediat., Sch. Med., Tokushima Univ.]

Between 1952 and 1954 children under 5 years of age to the number of 7733 were examined, 1519 in 2 towns, and 2604 in 8 agricultural, 2434 in 8 mountain, and 1176 in 4 fishing, villages. The percentage incidence of angular stomatitis was, for the regions in that order, 4·7, 7·7, 9·2 and 6·7 and for the whole population 7·5. The results are tabulated in English to show also the distribution of cases according to age and sex and to ranges for the Kaup Davenport index [no reference in English]. Of the 577 children affected only 15 were among 1758 examined while under 1 year of age; of the 15, 6 were breast fed and 5 had been partly fed on dried milk fortified with vitamins. The condition was much commoner after 3 years of age, among malnourished than among well nourished children, and among boys than among girls. (From summary.)—D. Harvey.

3654

KERPPOLA, W. **The content of riboflavin and riboflavin-containing coenzymes in the blood in health and in various diseases, in particular schizophrenia, neurocirculatory asthenia and tuberculosis.** *Acta med. scand.*, 1955–56, **153**, 33–48. [1. Dept. Med., Univ. Helsinki.]

Total and esterified riboflavin, containing riboflavin-5-phosphate and flavin adenine dinucleotide, were estimated in the blood of 60 normal subjects and 445 patients. Details of the methods are given. In the normal series the mean blood value in μg. per 100 ml. was for total riboflavin 6·68 with range 4·9 to 10·4 and for esterified riboflavin 5·51 with range 4·3 to 7·1. In schizophrenia, neurocirculatory asthenia (neurasthenia) and disseminated sclerosis, total riboflavin was not reduced except in about 20 per cent. of the patients with neurasthenia, but esterified riboflavin was significantly reduced in many; the mean values were 3·17, 3·58 and 3·69, respectively. There was a smaller, but significant, reduction of esterified riboflavin in gastric and duodenal ulcer, bronchial asthma and chronic colitis, all of them psychosomatic diseases, and in rheumatic diseases and tuberculosis. In some patients with obesity associated with hypertension and diabetes esterified riboflavin was reduced. In all other conditions studied there was no significant change except in myeloid leucaemia with high white cell counts when total and particularly esterified riboflavin were high because of the riboflavin content of the leucocytes. Treatment with riboflavin raised low riboflavin values but had no appreciable effect on clinical condition. The findings and the fact that in most of the individuals studied there was no clinical sign of riboflavin deficiency are considered evidence for the absence of any appreciable deficiency of riboflavin in Finland.—L. Wills.

3655

KOKIL, S. Über die Anaemie bei Dermatitis seborrhoides und ihre Beeinflussung durch Biotin. **[Anaemia in seborrhoeic dermatitis and the effect on it of biotin.]** *Ann. paediat.*, 1956, **186**, 79–82. [Kinderabt., Zentralkrankenhaus, Afula, Israel.] English and French summaries.

A moderate degree of normocytic or macrocytic but not of megaloblastic anaemia was found in 10 infants, aged from 2½ weeks to 3½ months, with seborrhoeic dermatitis. After oral treatment for from 14 to 21 days with 5 mg. biotin daily the dermatitis cleared and the anaemia improved in all but 2 patients with complications.—L. Wills.

3656

ZARAFONETIS, C. J. D., CURTIS, A. C. and SHAW, J. M. **Treatment of pemphigus with potassium para-aminobenzoate.** *Amer. J. Med. Sci.*, 1956, **231**, 30–49. [Dept. Int. Med., Sch. Med., Temple Univ., Philadelphia, Pa.] Interlingua summary.

Eighteen patients with pemphigus were treated with potassium *p*-aminobenzoate, 18 to 24 g. daily, usually given by mouth; in some cortisone or ACTH was given also. The cases are described in detail. Anorexia and hypoglycaemia developed in some patients, but treatment could be renewed when appetite returned. Some improvement was obtained in 15 patients treated for long periods, none in 3 treated for a short time; in 8 patients there was complete suppression of the skin lesions. There was some evidence of a synergic relation between potassium *p*-aminobenzoate and cortisone.

3657

MARQUEZ, L. R., CHESLOCK, K. E. and REYNOLDS, M. S. **Interrelationships of methionine and vitamin B_6 in human subjects.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90**, 352–355. [Dept. Food. Nutrit., Sch. Home Econ., Univ. Wisconsin, Madison.]

Four normal adult women took part in 2 metabolic experiments each lasting 21 days, with an

interval of 3 months between them. The basal diet low in vitamin B_6 was the same in both except that nicotinic acid was used in the first and nicotinamide in the second. The subjects took the basal diet alone for 9 days, then with a supplement of 8 g. *dl*-methionine daily for 6 days and finally with 8 g. *dl*-methionine and 10 mg. pyridoxine for 6 days. The methionine supplement did not affect the amount of vitamin B_6 and its metabolites excreted in the urine. Methionine alone did not increase the amount of N^1-methylnicotinamide excreted, but with pyridoxine as well excretion of methyl derivatives increased when nicotinamide but not when nicotinic acid was included in the diet.—A. M. Copping.

3658

BENHAMOU, E. and TIMSIT, M. Les polynévrites de l'isoniazide. [**Polyneuritis produced by isoniazid.**] *Presse méd.*, 1956, **64,** 199–202. [Algiers.]

Of 18 adults with uncomplicated tuberculous meningitis treated for from 6 to 10 weeks with from 15 to 25 mg. isoniazid per kg. bodyweight together with streptomycin and *p*-aminosalicylic acid, 8 developed severe polyneuritis which responded to reduction or withdrawal of the dose of isoniazid and administration of pyridoxine and vitamins B_1 and B_{12}. Treatment with isoniazid could be renewed if large amounts of pyridoxine were given at the same time. The signs of polyneuritis were associated with digestive troubles, erythema and glossitis, psychoses and sometimes convulsions. The syndrome was similar in all respects to that in experimental deficiency of vitamin B_6 due to the antagonist deoxypyridoxine, and the conditions are believed to be identical.

L. Wills.

LAWSON, D. F., DEGARIS, C. N. and BOLTON, J. H. **Folic acid and reproductive efficiency.** *Med. J. Austral.*, 1953, i, 848. [Women's Hosp., Melbourne.]

With a lymphocyte count of less than 1500 per c.mm. as an index of folic acid deficiency, 77 women, 21 primigravidae and 56 multigravidae, were selected for investigation.

Among the 56 multigravidae thus selected, the outcome of 145 pregnancies untreated with folic acid, and of 53 during which treatment with folic acid was given for the whole or greater part of gestation, was compared with the outcome of 138 pregnancies of 56 apparently normal multigravidae.

From the 145 pregnancies without folic acid treatment the number of full-term normal children was 41, and from the 53 pregnancies with folic acid treatment and the 138 normal pregnancies, the respective numbers were 42 and 106. It is, therefore, considered probable that some relationship exists between a low lymphocyte count and presumed folic acid deficiency, and the inability to carry a pregnancy successfully to term.

TITOV, K. G. and RYZHIK, D. L. Primenenie folievoi kisloty pri zabolevaniyakh u detei. [**The use of folic acid in children's disorders.**] *Pediatriya*, 1955, No. 1, 49–54. [Detskoi Klin., Med. Inst., Tashkent.]

Fifty children from 3 months to 9 years old were selected for treatment with folic acid; infants up to a year old received 1 or 2 mg. twice daily, those of 2 to 4 years 2 mg. 2 or 3 times daily and those of 5 years or more 2 mg. 3 or 4 times daily. Most of the children were dystrophic and 16 of them were severely anaemic. The causes were different; 2 children were tuberculous, 1 had sprue, others had pellagra, active rickets or other nutritional disorders.

Most of the children with anaemia showed a good response to treatment, with increase in circulating Hb and red cells and improvement in appetite and weight gain. Children with toxic dyspepsia, rickets and multiple vitamin deficiencies gave little or no response. Some dystrophic children showed very rapid improvement in appetite and weight.

It is concluded that folic acid may have a wide use in children's disorders.—D. Duncan.

LEAR, A. A. and CASTLE, W. B. **Supplemental folic acid therapy in pernicious anemia: the effect on erythropoiesis and serum vitamin B_{12} concentrations in selected cases.** *J. Lab. Clin. Med.*, 1956, **47,** 88–97. [Thorndike Mem. Lab., Boston, Mass.]

The 35 patients selected had pernicious anaemia, diagnosed on the presence of achlorhydria, macrocytes with abnormal bone marrow, and a characteristic haematological response to purified liver extract or vitamin B_{12}. All had been maintained in remission for at least 2 years by that treatment, but had had Hb values below 12·5 g. per cent. for a year or more. All continued to receive their normal maintenance treatment, but the doses were increased; 24 of the patients received 30 μg. crystalline vitamin B_{12} by intramuscular injection every 2 weeks for up to a year, and the other 11 had at similar intervals Liver Injection U.S.P. supposed to contain 20 μg. vitamin B_{12}. After the first 6 months at those levels of dosage each patient took in addition for the second 6 months 5 mg. folic acid daily by mouth.

Of the patients given more vitamin B_{12}, 5 had a significant and sustained rise in Hb at the end of 6 months. None of the others had a significant

change in either direction during the year, except one who responded to Fe and proved to have associated Fe deficiency. Initially 20 patients had serum vitamin B_{12} values below 100 $\mu\mu$g. per ml., but only 2 continued to do so after 6 months and none at the end of the year. There was wide variation. In 18 of 27 patients, for whom serum vitamin B_{12} was estimated throughout the experiment, there was a fall after administration of folic acid, and in 16 of them the fall was of more than 20 per cent.

Folic acid deficiency was considered not to be important in patients receiving adequate treatment with vitamin B_{12}, and a supplement of folic acid might even be inadvisable because of its effect in lowering serum vitamin B_{12}.—D. Duncan.

DAS GUPTA, C. R., CHATTERJEA, J. B. and RAY, R. N. **Role of citrovorum factor in nutritional macrocytic anaemia.** *J. Indian Med. Assoc.*, 1956, **26,** 85–91. [Dept. Haematol., Sch. Trop. Med., Calcutta.]

Seven patients aged from 24 to 54 years, all with nutritional megaloblastic anaemia, were treated with leucovorin. The diets of all were poor in animal protein. Four showed a good initial response to 18 mg. and one to 36 mg. when those amounts were divided into 6 consecutive daily doses. One showed fair improvement and one gave no response. The response was sustained in only 2 patients; the others subsequently required folic acid, a high-protein diet or crude liver extract.

LOWENSTEIN, L., PICK, C. and PHILPOTT, N. (with LALONDE, M.) **Megaloblastic anemia of pregnancy and the puerperium.** *Amer. J. Obstet. Gynecol.*, 1955, **70,** 1309–1337. [Dept. Med., Royal Victoria Hosp., McGill Med. Sch., Montreal.]

Megaloblastic anaemia was discovered by tests of the bone marrow in 18 patients between 1949 and 1952; in 9 it was detected during pregnancy and in 9 after delivery. The diet of 12 patients was said to be deficient, usually in animal protein, fruit and vegetables; for 2 other patients diet was said to be satisfactory, and for the other 4 details were not available. Only 2 patients complained of sore mouth or tongue and 14 of excessive fatigue; otherwise signs and symptoms were not specific. One patient was overweight, most of them "seemed underweight". Smoothness of the tongue was present in 6, ulcers of the tongue in 1, gingivitis in 2 and perlèche in 2. Gastric analysis with histamine showed achlorhydria in 1 and hypochlorhydria in 2, but normal acidity in 7 of the 10 patients examined. All other signs were inconstant. Most of the cases were found early in the period of study, and the use of polyvitamin supplements increased; from 1953, when vitamin B_{12} and folic acid were added to the supplements, no case was seen.

The peripheral blood showed no constant picture and variations of it were seen from macrocytic to microcytic and from hypochromic to hyperchromic, but the bone marrow always contained intermediate megaloblasts and macrogranulocytes. Such changes in the bone marrow were never found in normal women in pregnancy or the puerperium, or in other forms of anaemia.

One patient responded to vitamin B_{12} given by mouth and 2 failed to respond. Two responded to vitamin B_{12} given by intramuscular injection, one gave a partial response and 4 failed to respond. Four responded well and 1 less well to folic acid and 3 failed to respond, but 6 responded to folinic acid and none failed. Six needed Fe before recovery was complete, and 3 showed spontaneous remission after delivery. The view is not supported that megaloblastic anaemia of pregnancy and the puerperium has a different etiology in tropical and temperate regions; it is considered that a deficient diet is responsible in both instances, although the specific deficiency may differ. The deficiency may be of vitamin B_{12}, folic acid, or perhaps an unknown substance. The best therapeutic response was obtained with folic or folinic acid.

There are 114 references.—L. Wills.

WELBOURN, R. B., NELSON, M. G. and ZACHARIAS, F. J. **Megaloblastic anaemia following gastric resection: report of ten cases.** *Brit. J. Surg.*, 1955–56, **43,** 422–428. [Dept. Surg., Queen's Univ., Belfast.]

Histories are given of 10 patients who were found to have megaloblastic anaemia from 1 to 10 years after total or partial removal of the stomach. Of 6 patients studied for 4 years after total gastrectomy and given no prophylactic treatment, 2 of the 4 surviving after 3 years had megaloblastic anaemia and by the fourth year all 3 survivors had it. Besides the 3 there were 2 patients operated on elsewhere, in whom the anaemia was found after 5 and 6 years. In the 5 patients with only part of the stomach removed it was never possible to incriminate the operation as the sole or even the main cause of the anaemia, and 3 of them ate grossly deficient diets. Macrocytes were sometimes found in the peripheral blood before the anaemia developed, and are to be

regarded as an early warning sign. Seven of the patients were treated with vitamin B_{12} parenterally: 4 gave a satisfactory response, 1 died, 1 responded when folic acid was given also and the seventh responded to liver extract, folic acid and Fe. Three of the patients were treated parenterally with liver extract, to which 2 responded well, but one of them had persistent macrocytes, and the third was not followed up.

It is considered that all patients who have all or most of the stomach removed should receive vitamin B_{12} parenterally.—D. Duncan.

TÖTTERMAN, G. and AHRENBERG, P. **The age distribution in pernicious tapeworm anemia and Addisonian pernicious anemia.** *Acta med. scand.*, 1956, **153,** 421–426. [Med. Dept., Maria Hosp., Helsinki.]

The age distribution curves of 930 patients with pernicious anaemia and of 400 with tapeworm pernicious anaemia were compared; the former showed a slow rise to the fourth decade followed by a steep rise to a maximum at the sixth decade followed by a slight fall, and the latter a similar curve with a less steep rise to the sixth decade and a steeper fall after it. The degree of infestation with tapeworm is highest in the fourth decade, though the maximum incidence of anaemia is in the sixth decade. It is argued that the findings show that in subjects with tapeworm a latent period is required before anaemia develops.

MEYER, L. M., JIMINEZ-CASADO, M. and ARKUN, S. N. **Further observations on the oral administration of Co^{60} vitamin B^{12} to normal persons, patients with pernicious anemia, and subjects with various medical disorders.** *Acta med. scand.*, 1955–56, **153,** 153–158. [Third (New York Univ.) Med. Serv., Goldwater Mem. Hosp., Welfare Island, N.Y.]

^{60}Co was estimated in the stools after oral administration of 0·5 μg. ^{60}Co vitamin B_{12} (220 μC. per μg.). In 6 normal subjects excretion was within the usually accepted range of up to 50 per cent. of the intake, and showed the usual variation from person to person and in repeat tests. Similar results were obtained for 36 of 39 patients with disorders other than pernicious anaemia, but for 3 of them with cirrhosis of the liver, idiopathic thrombocytopenic purpura and colectomy the excretion exceeded 50 per cent. of the test dose. There was no apparent relation between age or presence of free HCl in the gastric juice and the amount of ^{60}Co excreted. The findings in 11 cases of pernicious anaemia confirmed those of other workers. Administration of 2 mg. folic acid with the test dose reduced the excretion of ^{60}Co in 1 only of the 11 cases.—L. Wills.

ARIAS, I. M., APT, L. and POLLYCOVE, M. **Absorption of radioactive vitamin B^{12} in nonanemic patients with combined-system disease.** *New Engl. J. Med.*, 1955, **253,** 1005–1010. [Radioisotope Unit., Veterans Admin. Hosp., Boston, Mass.]

Absorption of vitamin B_{12} was measured from the uptake of radio-activity by the liver after an oral test dose of 0·5 μg. radio-active vitamin B_{12} with a specific activity of 0·786 mC. per μg. In 4 non-anaemic patients with combined-system disease and no free acid or intrinsic factor in the gastric juice, the liver count after the oral test dose varied from 0 to 19 per cent. of the count obtained after the same dose given parenterally; the count increased to from 59 to 63 per cent. of that after the parenteral dose when the oral dose was combined with normal human gastric juice. None of the 4 patients had received folic acid, though 3 had previously received vitamin B_{12}. In 11 other subjects, 5 with histamine-resistant achlorhydria, the liver count after the oral dose ranged from 40 to 68 per cent. of the count after the parenteral dose. It is suggested that the uptake by the liver of radio-activity after an oral test dose of radio-active vitamin B_{12} might serve as a useful diagnostic test of combined-system disease.—L. Wills.

HALSTED, J. A., LEWIS, P. M. and GASSTER, M. **Absorption of radioactive vitamin B^{12} in the syndrome of megaloblastic anemia associated with intestinal stricture or anastomosis.** *Amer. J. Med.*, 1956, **20,** 42–52. [Veterans Admin. Centre, Los Angeles, Calif.]

A male patient had had numerous operations resulting in fistulae connecting loops of the small bowel, but their anatomical arrangement was obscure. He had 2 episodes of pronounced anaemia, macrocytic and hyperchromic, which responded well to parenteral treatment with vitamin B_{12}. A second patient had extensive diverticulitis of the stomach and intestines, and a blind pouch of the ascending colon as a result of anastomosis of the ileum to the transverse colon. Parenteral treatment with vitamin B_{12} was successful in his first episode of anaemia; folic acid failed

to maintain the remission, and vitamin B_{12} was again required.

Each of the patients was given by mouth vitamin B_{12} labelled with ^{60}Co, and absorption of the vitamin was estimated from the amount of radio-activity present in the faeces. The test was repeated when the vitamin was given with intrinsic factor or with antibiotics, aureomycin, neomycin, achromysin or gantrisin. Intrinsic factor did not decrease the amount of vitamin B_{12} recovered from the faeces of either patient, but aureomycin improved absorption in both, especially in the first patient. Achromycin caused some improvement, neomysin and gantrisin little or none. In the second patient aureomycin and achromysin reduced the diarrhoea from which the patient suffered, but diarrhoea was not the cause of the impaired absorption, because gantrisin also improved the diarrhoea but not the absorption. The results support the concept that the development of an abnormal bacterial flora in the intestine may be the cause of the failure by such patients to absorb enough vitamin B_{12}.

An addendum states that the favourable effect of achromysin was confirmed in another patient with megaloblastic anaemia after resection of the intestine.—D. Duncan.

MOLLIN, D. L., PITNEY, W. R., BAKER, S. J. and BRADLEY, J. E. **The plasma clearance and urinary excretion of parenterally administered ^{58}Co B_{12}.** *Blood, J. Hematol.*, 1956, **11**, 31–43. [Dept. Pathol. (Haematol.), Postgrad. Med. Sch., London.] Interlingua summary.

Serum concentration of vitamin B_{12} was normal in a group of 3 normal subjects, 3 patients with acute leucaemia and 1 with chronic lymphocytic leucaemia. Of 6 patients with low serum vitamin B_{12}, 5 had pernicious anaemia and 1 had nutritional megaloblastic anaemia. Two other patients with chronic myelocytic leucaemia had very high serum vitamin B_{12} concentrations.

In the 7 subjects with normal serum vitamin B_{12}, given injections of vitamin B_{12} labelled with ^{58}Co, 50 per cent. of the radio-activity had disappeared from the plasma in from 0·3 to 0·9 hr. After 24 hr. from 3 to 25 per cent. of the radio-activity remained in the plasma, and 2 subjects still had measurable activity after 7 days.

Clearance of injected vitamin B_{12} from the plasma was slow in the 3 patients with pernicious anaemia in relapse; 50 per cent. of the radio-activity had not disappeared in from 3 to 5 hr., and from 29 to 41 per cent. remained after 24 hr. In the 2 patients with less severe pernicious anaemia, clearance was normal, and in the patient with nutritional megaloblastic anaemia it was at the lower limit of the normal range. Clearance was much slower in the 2 patients with chronic myelocytic leucaemia than in any other; more than half the original radio-activity was present in the plasma after 24 hr., and in 1 patient 21 per cent. was present after 7 days. The other patient received massive doses of non-radio-active vitamin B_{12} for several days, after which clearance of another dose of labelled vitamin was faster than before, but still slower than in normal subjects.

There was good correlation between the concentrations of plasma vitamin B_{12} as calculated from the radio-activity and as estimated with *Euglena*.

Serum vitamin-B_{12}-binding capacity was tested in 1 subject from each group. The degree of unsaturation was 225 $\mu\mu$g. per ml. in the normal subject, 750 in a patient with pernicious anaemia and 1090 in a patient with myelocytic leucaemia.

There was no significant difference between the groups in the amount of radio-activity excreted in the urine in the 24 hr. after the injection.

D. Duncan.

MEYER, L. M., BERLIN, N. I., JIMINEZ-CASADO, M. and ARKUN, S. N. **Vit. B_{12} distribution, determined by surface body counting following parenteral administration of Co^{60} vit. B_{12}.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91**, 129–131. [New York Univ. Serv., Goldwater Mem. Hosp., New York.]

Radio-activity was measured over different organs of 14 subjects after intramuscular injection of 1 μg. vitamin B_{12} containing ^{60}Co. Activity was at a maximum over the liver, spleen and left kidney in that order, and was negligible in other regions. Activity appeared in the liver, spleen and left kidney within 30 min. of the injection and disappeared from the site of injection within from 3 to 4 hr. It persisted for varying periods up to 315 days in the liver of one subject. That and the great variation in time before maximum activity was reached made no clear pattern in healthy subjects or in patients with different chronic diseases. Injection of $^{60}CoCl_2$ into 6 subjects gave a very different pattern of absorption as indicated by radio-activity in the liver, spleen and kidney. It is suggested that in the present studies the amounts of vitamin B_{12} in the liver, spleen and kidney were related to the degree of radio-activity over those organs.

GALEOTTO, E. and RIZZI, R. La vitamina B_{12} nel trattamento del dolore postoperatorio. [**Vitamin B_{12} in the treatment of post-operative pain.**] *Acta vitaminol.*, 1955, **9,** 253–259. [Osp al Mare, Lido, Venice.] French, English, German and Spanish summaries.

Vitamin B_{12} was given by injection to 91 patients aged from 7 to 73, after different operations, as a total of from 3000 to 4000 μg. in 3 or 4 spaced doses within 24 hr., beginning 12 hr. before operation, or as a single dose of 5000 μg. given at the moment when the last stitches were put in. The investigation was incapable of quantitative treatment or control, but the results were considered satisfactory, the second mode of administration being superior. Besides the reduction of pain, general wellbeing was greater, and post-operative complications less, when vitamin B_{12} was given. Results were best of all when the treatment was combined with infiltration of the wound by delayed-action anaesthetics.—E. M. Hume.

3677

ADEZATI, L. and LOTTI, G. Effetto della vit. B_{12} sull'iperazoturia nella sindrome surrenometabolica. [**Effect of vitamin B_{12} on excess of nitrogen in the urine in the adrenometabolic syndrome.**] *Boll. Soc. ital. Biol. sper.*, 1955, **31,** 671–672. [Clin. Med. Gen., Univ. Genoa.]

In 3 patients with the syndrome of adrenal hyperactivity, the urinary output of N in 24 hr. was from 23 to 27 g. When they were given 1 mg. vitamin B_{12} by subcutaneous injection, the loss in the 3 subjects was reduced to 12, 10 and 12 g.—E. M. Hume.

PLANCHART, A. Evolución de la glutationemia y de la glucemia de obesos y de diabéticos durante la sobre-carga de glucoso después de la administración de B_{12}. [**Behaviour of blood glutathione and blood sugar in obese subjects and diabetics during a glucose tolerance test after administration of vitamin B_{12}.**] *Arch. venezol. Nutricion*, 1955, **6,** 23–33. [Inst. Nac. Nutrición.] English and German summaries.

There were 41 subjects, obese or diabetic [number of each not stated] ; most of the diabetics were controlled by diet or insulin. Blood sugar and glutathione were estimated at intervals after an oral test dose of 100 g. glucose. The test was repeated after 1000 μg. vitamin B_{12} had been given by vein daily for 10 days. The results are presented in tables and graphs.

In the obese subjects the blood sugar curve was considered to be " diabetoid ", but after treatment with vitamin B_{12} it became normal. In diabetic subjects the blood sugar began to rise later after treatment with vitamin B_{12}, but the level at the third hour was equally high before and after treatment.

In obese subjects blood glutathione reached a peak after 2 hr. and then fell ; the peak was lower and the fall steeper after vitamin B_{12}. In diabetics, blood glutathione showed a similar, but much lower, peak before treatment, but after treatment the value was initially higher and rose in the course of the blood sugar tolerance test.

It is suggested that it may be the effect of vitamin B_{12} on glutathione in the blood that is the cause of the difference in the blood sugar curve.

KARLIN, R. Variation du taux de vitamine B_{12} dans le lait de femme. Effet de l'administration de B_{12} sur ce taux. [**Vitamin B_{12} content of human milk, and the effect on it of giving vitamin B_{12}.**] *Pédiatrie*, 1956, **11**, 111–115. [Inst. Pasteur, Lyons.]

The vitamin B_{12} content of the milk of 10 mothers fell from about 330 mμg. per 100 ml. in the colostrum on the day of delivery to under 50 on the 4th day. Estimations on pooled samples of milk showed that the mean value fell from between 25 and 50 to under 25 during 8 months of lactation. Vitamin B_{12} given by mouth, alone or with intrinsic factor, had little or no effect on the vitamin B_{12} content of the milk, but a single intramuscular injection of 100 μg. raised the value to about 270 mμg. per 100 ml.—L. Wills.

Vitamin C

3681

STEELE, B. F., LINER, R. L., PIERCE, Z. H. and WILLIAMS, H. H. **Ascorbic acid nutriture in the human. 2. Content of ascorbic acid in the white cells and sera of subjects receiving controlled low intakes of the vitamin.** *J. Nutrition*, 1955, **57**, 361–368. [Dept. Food Nutrit., Cornell Univ., Ithaca, N.Y.]

For part 1 see Abst. 2265, Vol. 23.

After 38 or 42 days of a diet providing about 10 mg. ascorbic acid daily the partly depleted subjects, 10 men and 3 women, received in the diet successively 20, 30 and 40 mg. ascorbic acid daily for 14, 11 or 14, and 7 or 11 days, respectively; the experiments lasted from 73 to 78 days. Ascorbic acid was estimated frequently in the white cells and blood serum.

The average ascorbic acid content of the white cells increased and then decreased during the time when 20 and 30 mg. ascorbic acid were given; that of the serum decreased. There was a significant increase of ascorbic acid in both white cells and serum on changing from 30 to 40 mg.
A. Hepburn.

NAMYSŁOWSKI, L. and DESPERAK-SECOMSKA, B. Stan wysycenia witaminą C wybranej grupy młodzieży akademickiej w latach 1952–1953. [**The vitamin C content of the blood in a selected group of students during 1952 and 1953.**] *Rocz. Państwowego Zakł. Hig.*, 1955, **6**, 289–301. Russian and English summaries.

Vitamin C was estimated in the blood of 100 students attending the Higher School of Physical Culture. Two-thirds showed values ranging from 0·03 to 0·30 mg. per cent. Loading tests showed that 21 of them required 10 days and 19 required 8 days to reach saturation. Changes in the gums were noted in 79 per cent. of the students. It is concluded that the diet was deficient in vitamin C and that the strenuous exercise had produced a state of vitamin C deficiency. (From summary.)

BONOMOLO, A., CRESTA, M. and FIORENTINI, M. Consumi di acido ascorbico, ascorbinemia e fragilità vasale in un gruppo di 88 famiglie. [**Intake of ascorbic acid, blood ascorbic acid and vascular fragility in a group of 88 families.**] *Arch. Fisiol.*, 1955, **55**, 182–186. [Ist. Nazionale Nutriz. C.N.R., Rome.]

As part of a dietary survey in the province of Salerno, the ascorbic acid intake of 88 families with 480 persons was investigated. The economic condition of the families was classified as bad for 44, moderate for 23, and good for 21. The ascorbic acid content of the diets recorded in the survey was calculated from tables of food composition, 50 per cent. loss being allowed for cooking. The percentage of families receiving less than the Recommended Dietary Allowances (1953) [presumably U.S.] was for those classed on an economic basis as bad 22·8, moderate 21·8, and good 4·7. Ascorbic acid was estimated in the blood of 151 persons from 36 of the families. The values bore no relation to the intakes. The mean value, in mg. per 100 ml. serum, was for those with a deficit of from 50 to 90 per cent. of the recommended allowance $0·78 \pm 0·10$; with a deficit of from 49 per cent. to an excess of 10 per cent. $0·75 \pm 0·08$; and with an excess of from 11 to 80 per cent. $0·67 \pm 0·15$. The corresponding values for 267 persons, amongst whom all the 88 families were represented, were $0·67 \pm 0·09$, $0·75 \pm 0·02$, and $0·69 \pm 0·09$. No sign of deficiency was seen, and measurement of capillary resistance was considered to have no value.—E. M. Hume.

3684

CLEIN, N. W. **Acerola juice—the richest known source of vitamin C. A clinical study in infants.** *J. Pediat.*, 1956, **48**, 140–145. [Dept. Paediat., Sch. Med., Univ. Washington, Seattle.]

Juice from the acerola or Puerto Rican "cherry" (*Malpighia punicifolia*, L.) is one of the richest sources of ascorbic acid, containing on the average 1700 mg. per 100 ml., with a range from 1200 to 4000 mg. A clinical test over 12 months is reported with 30 newborn infants given from 25 to 50 mg. ascorbic acid from acerola juice mixed

with apple juice. All showed better than average growth and after 4 months values for blood ascorbic acid ranged, with 1 exception, from 1·5 to 2·7 mg. per 100 ml. Sensitivity tests on 100 children showed that while some were allergic to orange juice, none was allergic to acerola juice.

CZINA, G., KÖZÉPESY, L. and BIRÓ, L. Der Vitamin-C-Haushalt bei der Lungentuberkulose. [**Vitamin C metabolism in pulmonary tuberculosis.**] *Internat. Ztschr. Vitaminforsch.* 1955, **26,** 262 – 271. [Lungenkrankenabt., Komitätsspital, Gyula.] French and English summaries.

Deficiency of vitamin C was assessed by a modified saturation test in which the vitamin was given intravenously. In normal subjects and in 96 patients with tuberculosis the degree of unsaturation was greater in winter, when all the subjects showed some degree of deficiency, than in summer. The deficit was greater in active than in inactive cases ; treatment with streptomycin or by pneumothorax reduced the degree of deficiency except where there was cavity formation. Patients with tuberculous pleurisy showed a moderate deficit or none.—L. Wills.

SELIGER, H. Der Einfluss der Askorbinsäure auf die Biosynthese der Kortikosteroide und dessen klinische Bedeutung. [**Influence of ascorbic acid on the biosynthesis of corticosteroids and its clinical significance.**] *Ztschr. ges. inn. Med.*, 1955, **10,** 1060–1063. [Schmiedefeld am Rennsteig.]

Studies have been reported showing the stimulating effect of ascorbic acid on biosynthesis of corticosteroids, so tests were made on 4 patients with proved adrenal insufficiency. By giving from 200 to 300 mg. ascorbic acid daily it was possible to increase the production of corticosteroids so that doses of adrenocorticotropic hormone lower by from 30 to 40 per cent. were sufficient. The reduction helped to prevent undesirable side-effects of treatment.—A. M. Copping.

3688

LIMBOS, P. and COURTOIS, G. Un nouveau cas d'onyalai observé à Stanleyville. [**A new case of onyalai observed at Stanleyville.**] *Ann. Soc. belg. Méd. trop.*, 1955, **35,** 187–191. [Hôp. Congolais, Stanleyville.] Flemish summary.

An account was previously given of a case of onyalai in Stanleyville, treated with ascorbic acid (Abst. 3461, Vol. 23).

A second case is now described. The patient, a well nourished native of 30, showed the typical blood bullae in the mouth but no other clinical signs. Deficiency of blood platelets and prolonged bleeding time confirmed the diagnosis. The blood ascorbic acid value was 0·7 mg. per cent. The only treatment was with 2 g. ascorbic acid daily in 4 intravenous injections, and the patient was discharged within a week. He was seen at intervals subsequently. He never relapsed and his blood ascorbic acid value fluctuated from 0·8 to 1·35 mg. per cent. The attack had always been recognised as benign, and it is not considered possible to conclude whether the treatment with ascorbic acid played any significant part in the quick recovery.

HARKINS, H. P. **Prevention of postoperative adenotonsillectomy bleeding with vitamin K and vitamin C.** *Ann. Otol. Rhinol. Laryngol.*, 1955, **64,** 1137–1145. [Dept. Otolaryngol., Hahnemann Med. Coll., Philadelphia, Pa.]

When 100 children were given 10 mg. vitamin K and 400 mg. vitamin C daily in divided doses for 5 days before and 5 days after removal of adenoids and tonsils there was a highly significant reduction in the incidence of post-operative bleeding compared with the incidence among 100 similar untreated children. Administration of acetylsalicylic acid did not affect the incidence of bleeding. There was no significant difference between the average bleeding and coagulation times for the groups and no sign of toxicity from the vitamins.

DENTAL DISEASES

3694

PHILLIPS, P. H. **Recent progress in dietary research and dental caries.** *J. Amer. Dietetic Assoc.*, 1956, **32,** 110–114. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

3695

DAVIES, G. N. **Dental conditions among the Polynesians of Pukapuka (Danger Island). 1. General background and the prevalence of malocclusion.** *J. Dent. Res.*, 1956, **35,** 115–131. [Dept. Prevent. Dent., Univ. Otago Dent. Sch., Dunedin.]

3696

SAVARA, B. S. and SUHER, T. **Dental caries in children one to six years of age as related to socioeconomic level, food habits, and toothbrushing.** *J. Dent. Res.*, 1955, **34,** 870–875. [Dent. Sch., Univ. Oregon, Portland.]

After more careful evaluation of the socioeconomic status of the parents of 279 of the 650 children previously studied (Title 2289, Vol. 23), it was found that caries incidence was not correlated with parents' income or frequency of toothbrushing, eating between meals, or consumption of cake, pie, ice-cream, jelly, cookies, candy or fresh fruit. There was a small correlation ($r = + 0{\cdot}2$) between caries incidence and frequency of eating canned fruit. Children of more highly educated parents tended to have less caries.—W. M. Deans.

3697

HADJIMARKOS, D. M. **Geographic variations of dental caries in Oregon. 7. Caries prevalence among children in the Blue Mountains region.** *J. Pediat.*, 1956, **48,** 195–201. [Dept. Pub. Health, Dent. Sch., Univ. Oregon, Portland.]

The numbers of decayed, missing and filled (DMF) teeth were recorded for 139 and 172 children aged from 14 to 16 years in Baker and Union counties, respectively. For the combined age groups the rates were 10·5 and 11·2. When the data were assembled with those for other districts (see Abst. 4043, Vol. 19 and earlier parts 5, *Amer. J. Pub. Health*, 1951, **41,** 1052 and 6, *New York Dent. J.*, 1955, **21,** 11) it was seen that in Oregon DMF rates were lower to the east than to the west of Cascade Range. For possible explanation the Weather Bureau's records of sunshine and the F content of water supplies were investigated. The prevalence of caries was related inversely to the amount of sunshine ; the amount of F in drinking water was without effect. Further studies of the first of these and of the effects of selenium (see Abst. 2892, Vol. 22) are suggested.

3698

CARTER, W. J., HOERMAN, K. C., ENGLANDER, H. R. and SHKLAIR, I. L. **Oral phosphatase levels and caries activity.** *Science*, 1956, **123,** 325–326. [Sch. Dent., Univ. Kansas City, Mo.]

Phosphatases were estimated in saliva from 100 naval recruits and from 2 other groups each of 26 subjects in whom caries was absent or active. The mean values for acid phosphatase were 4·72, 5·65 and 7·61 units and for alkaline phosphatase 0·57, 0·58 and 0·68 unit, respectively. The differences between the means for the caries-free and caries-active groups were not statistically significant. It is suggested that the enzymes may be present in so many of the organisms normally occurring in the mouth that a connection between them and the occurrence of caries may be masked.

D. Harvey.

3699

JACOBSON, F. L., ESSELBAUGH, N. C. and HARD, M. M. **Dental caries experience among Washington-born and -reared freshman students at the State College of Washington in 1950.** *J. Dent. Res.*, 1956, **35,** 132–136. [Washington Agric. Exp. Stat., Pullman.]

The main purpose of the study was to find an area of high and one of low dental caries for further study of the nutritional and dental state of adolescents.

The method of examination was by bite-wing X-ray survey and in 699 students 20 teeth were examined per student. The average count of decayed, missing and filled (DMF) teeth was 14·64 with the average for women slightly higher than for men. The results were classified on a geographical basis and areas with DMF counts of 16·2 and 13·4 were selected for further study.

3700

ODLAND, L. M., PAGE, L. and DOHRMAN, S. T. **Dental caries experience of Montana students.** *J. Amer. Dietetic Assoc.*, 1955, **31,** 1218–1222. [Dept. Home Econ. Res., Montana Agric. Exp. Stat., Bozeman.]

Two sets of data are dealt with, the first referring to students of both sexes aged from 16 to 28 years who were natives of and had been brought up in Montana, the second to 2 groups of 15-year-old schoolchildren who had lived their lives at Bozeman and whose drinking water had negligible amounts of F, or at Great Falls with 0·9 p.p.m. F in their water supply.

Scores for decayed, missing and filled (DMF) teeth are tabulated for the students according to sex and age by single year from 16 to 20 +. The average total DMF rate for all 294 subjects was 13·4, for the 170 men 12·0 and for the 124 women 15·2. When the subjects were grouped according to the F content of their water supplies the mean rate was 15·6 for 137 subjects with from 0·0 to 0·2 p.p.m. F and 5·7 for 7 with from 1·2 to 1·7 p.p.m.

Among the children the difference was striking with mean rates 12·2 and 6·3 for DMF teeth at Bozeman and Great Falls, respectively. They were higher for girls than for boys in each place, 13·2 and 11·1 at Bozeman and 6·9 and 5·6 at Great Falls; 7-day diet studies showed that, in general, nutrient intakes were better for boys than for girls. The intake of total carbohydrate was not related in either place to the scores, and from analyses of blood serum there was no evidence that intake of F interfered with utilisation of ascorbic acid.—D. Harvey.

3701

GOLDSWORTHY, N. E. **Observations on the use of fluorine for the partial control of dental caries.** *Med. J. Austral.*, 1953, i, 281–285. [Inst. Dent. Res., United Dental Hosp., Sydney.]

The incidence of chronic endemic dental fluorosis and the addition of fluorine to domestic water supplies are reviewed in relation to the occurrence of dental caries. The advantages and disadvantages of adding fluorine to drinking water are discussed and compared with those of applying fluoride directly to erupted teeth. The mode of action of fluoride in controlling caries is discussed and considered to be different in the two procedures.

Reference is made to the absence of precise information on the incidence of caries in Australia and to the apparent lack of interest among medical men and dentists in the disease and in measures for its prevention.—M. H. Pierce.

3702

AMIES, A. B. P. and PINCUS, P. **Fluorine and dental caries.** *Med. J. Austral.*, 1953, ii, 41–44. [Dent. Sch., Univ. Melbourne.]

A general article discusses the arguments for and against addition of fluorine to drinking water, in its biochemical and socio-economic aspects. Tea drinking on the scale usual in Australia and New Zealand may with some waters make a very important contribution to F intake. The effect of F may be only to postpone and not permanently to prevent the onset of caries. The incidence of caries in Australia is not accurately known and should be ascertained before any large-scale addition of F to water is undertaken.

E. M. Hume.

3703

SULLIVAN, H. R. and GOLDSWORTHY, N. E. **A discussion of dietetic and nutritional factors in relation to dental caries and of difficulties in effecting changes in food habits.** *Med. J. Austral.*, 1954, ii, 136–139. [Inst. Dent. Res., United Dent. Hosp., Sydney.]

The freedom from dental caries of children living in a large home on a diet low in refined carbohydrates (see Abst. 3730, Vol. 24) is used as the text for a general article. The prejudices connected with tradition and social position and the genuine preference for certain foods, especially sweet things, that would have to be overcome before any abandonment of refined carbohydrates could be achieved, are stressed. In addition, in world conditions as they are to-day, there seems to be little place for the raw, unprocessed foodstuff. Concentrated and processed foods that can be stored are necessary.

In attempting to assess the extent to which intake of refined carbohydrate must be reduced in order to decrease dental caries, it is considered that exclusion of snacks and confinement to 3 good meals daily would go a long way in the right direction. It is recognised that preservation of health as such and not for any special purpose is not a strong enough motive to make people change pleasant habits for less pleasant ones.

E. M. Hume.

3704

CLEMENTS, F. W. **The teeth and food.** *Med. J. Austral.*, 1955, i, 297 – 302. [Inst. Child Health, Sydney.]

In a lecture the history of dental caries, modern developments supporting the chemico-parasitic theory of its cause, and the effects of systemic nutrition on tooth structure are discussed. Special reference is made to the importance of sugar in the etiology of caries, and to the influence of social and intellectual environment. Doubt is expressed as to the readiness of the community as a whole to accept any limitation of its sugar intake for the purpose of combating caries.—M. H. Pierce.

3705

MINISTRY OF HEALTH, CANBERRA. **Measures for the partial prevention of dental caries.** *Med. J. Austral.*, 1955, i, 329–330. [Canberra.]

A report on the influence of climate, age and body size on water consumption in reference to fluoridation was accepted by the National Health and Medical Research Council. It was concluded that temperature is the only important climatic factor to be considered. For climatic zones of Australia with normal maximum temperatures from 45° to 100° F. fluorine is recommended to be added to water in p.p.m. from 1·4 to 0·4, decreasing by 0·1 p.p.m. for each 5° rise of temperature.

3707

ZIEGLER, E. Kritische Betrachtungen über die Fluordosierung bei den verschiendenen Methoden der Cariesbekämpfung mit Fluor. [**Critique of fluorine dosage in the several methods of combating caries with fluorine.**] *Schweiz. med. Wochenschr.*, 1956, **86,** 252–254. [Konradstrasse 7, Winterthur.]

In a general article recent work is discussed and it is concluded that for children the addition of fluoride to milk assures the correct intake of F, but if water is the vehicle, the intake of F varies with seasonal variations in the intake of water.

L. Wills.

3708

KNAPPWOST, A. Zur Fluor-Prophylaxe der Karies. Magnesiumfluorid und Calciumfluorid als physiologische und hochwirksame Kariesprophylaktika. [**Prevention of caries with fluorine. Magnesium fluoride and calcium fluoride as physiological and effective preventives of caries.**] *Deutsch. med. Wochenschr.*, 1956, **81,** 92–94. [Abt. Phys. Chem., Zahnärztl. Inst., Univ. Tübingen.]

This article includes brief references to work by the author on the mechanism of the prevention by fluorine of caries in the Syrian hamster (*Deutsch. zahnärztl. Ztg.*, 1952, **7,** 670, 681). It is deduced that F has 3 different effects: (1) it favours mineralisation of the teeth, (2) it favours, through its effect on the saliva, re-mineralisation of areas which have begun to be affected by caries, (3) by ion exchange hydroxylapatite is changed into the more resistant fluorohydroxylapatites. Fluoridation of the supply to a single household is advocated, with fluoride tablets, as in Switzerland, where, as, *e.g.*, for people in the country, it is not feasible on a larger scale. Since sodium fluoride tablets do not provide as regular a supply of F throughout the day as does fluoridated water, tablets of the relatively insoluble calcium or magnesium fluoride are recommended. Successful experiments on the prevention, by means of tablets of magnesium fluoride, of caries in hamsters given a cariogenic diet of sugars and white bread will be reported elsewhere.—W. M. Deans.

3709

PETERSON, J. K. and JORDAN, W. A. **Relative caries-inhibiting value of sodium silicofluoride and sodium fluoride.** *J. Dent. Res.*, 1956, **35,** 54–58. [Sect. Dent. Health, Minnesota Dept. Health, Minneapolis.]

In 1953 children in school grades 3 to 7, 610 in all, had topical applications, 4 of sodium silicofluoride on one side of the mouth and 4 of sodium fluoride on the other, or 2 of silicofluoride on one side and nothing on the other, or 1 of silicofluoride on one side and 4 of fluoride on the other. On examination in 1954, silicofluoride seemed to have had some effect in reducing incidence of caries, but less than fluoride; the differences were not significant, and less than half of the children had developed fresh lesions during the year.—W. M. Deans.

IMMUNITY

3712

De Toni, E. (Jr.) and Mitolo, G. R. La sensibilizzazione alle proteine del latte nel lattante. [**Sensitisation to milk proteins in the infant.**] *Lattante*, 1955, **26,** 562–572. [Ist. Clin. Pediat. G. Gaslini, Univ. Genoa.] English summary.

Intradermal tests with injection of 0·10 ml. milk, human and cow's, were made on 130 babies, not perceptibly allergic; 46 were on the breast and 84 were fed on cow's milk. They were in hospital recovering from different diseases, chiefly digestive disturbances. A reaction was classed as positive when within a few minutes a bleb at least 1 cm. in diameter was produced lasting for more than 15 min. All the breast-fed babies gave a negative response to both milks. Of the 84 babies fed on cow's milk, only 24 could be tested with human milk, and all gave a negative response. With cow's milk 10 out of 84 gave a positive result; some of those giving a positive reaction had digestive disturbances, but others had not. The observation is accepted as strong evidence for the superiority of human milk for the human infant.

3721

WAGNER, A. **The fallibility of the glucose tolerance test in the aged.** *Geriatrics*, 1955, **10,** 588–594. [Northwestern Univ. Med. Sch., Evanston, Ill.]

Tolerance curves were available for 108 women between 65 and 85 years of age with repeat examinations after 1 year for 82 and after 2 years for 27. They were examined clinically and were free from diabetes, liver disease and thyroid disorder. There was a wide variety of high and prolonged curves. The incidence of certain conditions which might be associated with diabetes was considered in relation to the occurrence of glycosuria, which appeared in 22 subjects during the tests; these conditions were myocardial infarction, albumin and casts in urine, over- or underweight, gain in weight and positive family history of diabetes. No correlation was found between their occurrence and the type of curve. It is concluded that aberration of the tolerance curve should not be taken alone in the diagnosis of diabetes; a complete clinical examination is essential and a persistently high fasting level is better than a high peak as a prognostic.—D. Harvey.

WOODHILL, J. M. and LOGAN, J. L. **Diabetic diets simplified: the core diet.** *Med. J. Austral.*, 1955, i, 960–962. [Royal Newcastle Hosp., N.S.W.]

The system of diets presented, called the core diet, is an extension of the line-ration scheme of R. D. Lawrence (The Diabetic Life, J. and A. Churchill, Ltd., London) and a simplification of that sponsored by the American Dietetic Association and the U.S. Public Health Service (Caso, Abst. 4285, Vol. 20). The two core diets provide 1800 and 2400 Cal. daily, and sample meals are given; there is a substitution sheet of equivalent portions and a list of free foods. The protein content is made as high as practicable, being determined by income as much as anything, and the fat content is as low as practicable. The core diet of 1800 Cal. provides daily about 175 g. carbohydrate, 75 g. protein and 90 g. fat, and that of 2400 Cal. proportionately larger amounts.

E. M. Hume.

SHUMAN, C. R., KEMP, R. L., COYNE, R. and WOHL, M. G. **Clinical use of sorbitol as a sweetening agent in diabetes mellitus.** *Amer. J. Clin. Nutrit.*, 1956, **4,** 61–67. [Temple Univ. Hosp., Philadelphia, Pa.]

Studies were made on 38 diabetic patients from 2 hospitals in Philadelphia who were given daily either three 100-g. helpings or one 200-g. helping of a sorbitol ice-cream containing, in g. per 100 g., fat 4·0, lactose 7·3, protein 4·4 and sorbitol 18. Estimations of glucose in blood during fasting and in urine were made at intervals during sorbitol administration and again when a fat-free sherbet was given with, per 100 g., 2·8 g. lactose, 1·7 g. protein and 17·1 g. sorbitol.

Sorbitol ice-cream did not significantly alter the diurnal blood glucose values in either mild or moderately severe diabetes. It is suggested that sorbitol ice-cream may, without reference to its energy equivalent, be allowed to patients with mild diabetes or moderate diabetes which is under control but that more information is required about its laxative action and its metabolic effects over long periods.—G. F. Garton.

BERTRAM, F., BENDFELDT, E. and OTTO, H. Indikationen und Erfolge der peroralen Behandlung des Diabetes mellitus mit einem Sulfonylharnstoffderivat. Bericht über 335 Fälle. [**Indications for and results of oral treatment of diabetes mellitus with a derivative of sulphonyl urea. Report on 335 cases.**] *Deutsch. med. Wochenschr.*, 1956, **81,** 274–278. [2. Med. Klin., Allg. Krankenhaus, Hamburg Barmbek.]

For a preliminary report see Abst. 2402, Vol. 26.

Now 335 diabetics, most of whom required insulin, have been treated with N_1-sulphanilyl-N_2-*n*-butylcarbamide, BZ 55, Nadisan (C. F. Boehringer und Söhne G.m.b.H., Mannheim-Waldhof), Invenol (Farbwerke Hoechst A.G., Frankfurt-Hoechst), and some have been under observation for up to 10 months. Studies of clinical chemistry will be reported elsewhere.

With Nadisan, generally 5, dropping to 2, 0·5-g. tablets daily for 10 or 14 days or longer, and diet, good control was achieved in 218 patients. Treatment failed in 85 and the result was doubtful in 32. Since Nadisan seems to have less effect than insulin on the rise of blood sugar after a meal, strict diet is essential. Side effects were few. In a discussion of the indications for treatment, great stress is now laid on constitutional type. The diabetes of the stocky, pyknic, possibly obese person (" Gegenregulationsdiabetes, diabète gras ") generally responded to Nadisan; among 110 patients of this type, the more recent the diabetes and the shorter the treatment with insulin, the better were the results. The amount of insulin previously required did not matter. Successes were much rarer in the more labile diabetes (" Insulinmangeldiabetes, diabète maigre ") found in thin, leptosome persons; and although some of the 41 young diabetics treated hitherto were able to do with less insulin than before, it is considered doubtful how far Nadisan will help them. In coma and pre-coma, Nadisan is useless, though it may be worth trying in mild, symptom-free acidosis.—W. M. Deans.

3729

FERNER, H. and RUNGE, W. Die Langerhansschen Inseln von Diabetikern nach Behandlung mit dem oralen Antidiabetikum BZ 55. [**The islets of Langerhans in diabetics after treatment with the oral remedy BZ 55.**] *Deutsch. med. Wochenschr.*, 1956, **81,** 331–333. [Anat. Inst., Univ. Hamburg.]

Histological post-mortem examination by the silver method of Gros-Schultze or a modification of Gomori's aldehyde fuchsin method of the pancreas of 3 patients with diabetes who had had in all 16, 13·5 and 50 g. of the antidiabetic substance BZ 55, also known as Nadisan (see Abst. 2402, Vol. 26) not long before death from causes other than diabetes, showed no sign of damage to the alpha cells; the islets of Langerhans differed in no way from those of diabetics not treated with BZ 55. It is suggested that BZ 55 acts by inhibiting the function of the alpha cells.—W. M. Deans.

GASTRO-INTESTINAL CONDITIONS

3731

HALLMAN, N., HJELT, L. and TÄHKÄ, H. Über zerebrale Schädigungen nach Gastroenteritis im Säuglingsalter: klinische und histopathologische Untersuchungen. [**Cerebral damage after gastro-enteritis in infants: clinical and histopathological studies.**] *Ann. Paediat. Fenn.*, 1956, **2,** 31–43. [Kinderklin., Univ. Helsinki.]

The cases are discussed of 2 infants who had severe gastro-enteritis at 6 and 7 weeks of age, respectively. Both infants got over the acute illness but neither made a good recovery. Both became spastic. One died at 7½ months with a terminal respiratory infection, the other at 1 year 7 months, mentally retarded. Post-mortem examination revealed in both diffuse destruction of cortical nerve cells, considerable demyelinisation and fibrotic glial formation. It is suggested that the gastro-enteritis and its accompanying K depletion and cerebral anoxia were at least partly responsible for the damage.—D. Duncan.

3732

FREUDENBERG, E. Ist die diätetische Behandlung der Säuglings-Enteritis entbehrlich geworden? [**Is the dietetic treatment of infantile diarrhoea no longer necessary?**] *Acta paediat.*, 1955, **44,** 579–583. [Kinderklin., Basle.] English, French and Spanish summaries.

The rapid feeding programme of Jadrníček and Mores (Abst. 934, Vol. 26) and others is criticised on the grounds that intestinal lesions may be present and that early feeding may result in bulky stools containing much water and minerals.

BOTHMA, F. Glutenvrij en eiwitarm brood. [**Gluten-free and low-protein bread.**] *Voeding*, 1956, **17,** 108–112. [Centraal Inst. Voedingsonderzoek T.N.O., Wageningen.]

Instructions were given earlier (Abst. 1727, Vol. 25) for baking buckwheat bread for patients with coeliac disease. Recipes and instructions are given here for bread from cornflour and carob bean meal and for a low-protein bread from wheat starch and carob bean meal. Both are yeast breads.—I. Leitch.

3738

ANDERSON, C. M. **Recent trends in the diagnosis and treatment of coeliac disease.** *Med. J. Austral.*, 1953, ii, 211–213. [Melbourne.]

The story of the incrimination of wheat gluten in coeliac disease is briefly sketched with an account of personal observations on the effect of withdrawing it from and restoring it to the diet of 15 patients. Instructions for a gluten-free diet and recipes for a gluten-free biscuit and loaf are given.—E. M. Hume.

3739

LINDSAY, M. K. M., NORDIN, B. E. C. and NORMAN, A. P. **Late prognosis in coeliac disease.** *Brit. Med. J.*, 1956, i, 14–18. [Brit. Postgrad. Med. Sch., Hammersmith Hosp., London, W.12.]

The condition of 25 adults who suffered from coeliac disease in childhood (Hardwick, Abst. 4885, Vol. 9) was re-assessed. None had received treatment with gluten-free diet. Four were still relapsing or had active disease and 4 showed minor degrees of malabsorption.

The findings support the view that coeliac disease is a chronic relapsing illness.

3740

MAFFIA, A. J. **Treatment of functional constipation with Prune-Malt.** *Arch. Pediat.*, 1955, **72,** 341–346. [Dept. Paediat., New York Med. Coll.]

The causes of constipation in infants and children are discussed.

Prune-Malt, a mixture containing prune and fig concentrate and non-diastatic malt syrup neutralised with potassium carbonate, was given to 100 constipated children aged 3 weeks to 8 years. Another group of 100 constipated children were untreated controls. As judged from the observations of the mothers during 3 weeks the proportions of children returning to normal and of children improving were greater in the treated than in the untreated group. Acceptability of the Prune-Malt was good in 32 per cent. [tabulated as 132], fair in 47 and poor in 21 per cent.—F. C. Aitken.

3741

DAWSON, A. M. **Continuous intragastric milk drip in the treatment of upper gastro-intestinal haemorrhage.** *Lancet*, 1956, **270,** 73–74. [Gastro-Enterol. Unit, Central Middlesex Hosp., London.]

From a study of 100 patients given routine treatment with, in alternate cases, 6 pints of milk in 24 hr. by intragastric drip, there was no evidence that healing of the ulcer could be hastened or that recurrence of haemorrhage could be prevented.

D. Harvey.

3742

DOLL, R., FRIEDLANDER, P. and PYGOTT, F. **Dietetic treatment of peptic ulcer.** *Lancet*, 1956, **270,** 5–9. [Gastro-Enterol. Dept., Central Middlesex Hosp.]

Thirty-two hospital patients with gastric ulcer were given the standard ulcer diet in 2-hourly feeds and a comparable group had normal hospital diet without fried food but with snacks at 10 a.m. and 9 p.m. Half the patients in each group received a full course of milk by intragastric drip. After 1 month the number of healed and nearly healed ulcers was not significantly different in the 2 groups. Gain of weight was not significantly different between the groups given milk drip, but for patients without milk drip, weight gain was

significantly greater in those on normal than in those on the ulcer diet. Patients on normal diet complained more frequently of pain but this may have been due to anxiety about the possible effect of unrestricted diet.

Two groups of outpatients with gastric and duodenal ulcers were advised in the one case to continue on ulcer diet and in the other to change to normal diet. Both were given supplies of alkaline powder for relief of pain. The percentage of patients re-admitted to hospital because of failure of treatment was higher in the first than in the second. The percentages of patients in whom ulcers were found to be healed at the end of 1 year and of patients who were free of pain during this time were about the same in the 2 groups.

It is concluded that dieting with bland foods does not increase the rate of healing of peptic ulcers.

F. C. Aitken.

3743

DOLL, R., PRICE, A. V., PYGOTT, F. and SANDERSON, P. H. **Continuous intragastric milk drip in treatment of uncomplicated gastric ulcer.** *Lancet*, 1956, **270**, 70–73. [Statistical Res. Unit, Med. Res. Counc.]

There were 164 patients, all of whom were given standard basic medical treatment and half of whom received the milk, some with and others without added alkali as sodium bicarbonate. In 2 patients the amounts of alkali were 80 and 140 g. daily. Effects were measured objectively by the rate of healing of the ulcer, which was studied radiographically (see Abst. 2771, Vol. 25), and subjectively by the patients' descriptions of symptoms. The number of ulcers which healed completely and the extents to which others improved were the same in patients with and without milk. There was evidence that relief of pain was quicker in those with than in those without milk and that the giving of alkali was advantageous. Average gain in bodyweight in the milk group, 7 lb. 0 oz., was greater than in the group without milk, 3 lb. 8 oz., and the advantage was found to persist nearly 3 months after the date of discharge from hospital.—D. Harvey.

3744

CROWE, P. J. and GOULSTON, S. **Post-gastrectomy dietary management.** *Med. J. Austral.*, 1954, ii, 430–433. [Clin. Res. Unit, Royal Prince Alfred Hosp., Sydney.]

The importance of diet in the prevention or reduction of post-gastrectomy syndromes, malnutrition and debility is discussed. The types of food recommended, and detailed menus for the 3 months after operation, are given, with the proximate composition and energy value of the diet. Six small meals are given daily; the aims are an early introduction of sufficient protein and energy to combat the loss of N and K which follows operation and a gradual increase in food intake each week.—M. H. Pierce.

This complex nutritional deficiency, a late sequel to gastrectomy, was first described by Lambling and Conte (*Bull. et Mém. Soc. méd. Hôp. Paris*, 18 February 1949, 151); it is quite distinct from the "dumping syndrome". Detailed case histories are given for 4 patients, all men, of whom 3 were edentulous and addicted to alcohol and 2 had tuberculosis; post-mortem findings are given for 2 of them. The main signs, which developed from 3 months to 6 years after operation, were diarrhoea, emaciation combined with oedema of the legs, anaemia with normal colour index, low blood protein and, in some, skin and mouth lesions suggestive of vitamin deficiencies. Two recovered on a regime of frequent small feedings of a diet mainly of skimmed milk fortified with synthetic amino acids and other nutrients, coupled with other measures. The etiology is discussed and it is considered that, in essence, the causes are mechanical disturbance due to overloading of the small intestine with unprepared food, and diminished production of pancreatic enzymes; a vicious circle is produced, leading to changes which unless promptly treated are irreversible.

THYROID DISEASE

3747

CLEMENTS, F. W. **The problem of endemic goitre.** *Med. J. Austral.*, 1953, ii, 251–254. [Inst. Child Health, Sydney.]

See Abst. 5292, Vol. 24.

3748

CLEMENTS, F. W. **A thyroid blocking agent as a cause of endemic goitre in Tasmania: preliminary communication.** *Med. J. Austral.*,

1955, ii, 369–371. [Inst. Child Health, Univ. Sydney.]

Two surveys of schoolchildren with an interval of 5 years between them supported the view that something other than deficiency of I in the diet was responsible for the occurrence of a significant amount of goitre in Tasmania. Tablets of KI were distributed to the children after the first survey, and the second survey showed a lower incidence among older age groups and in some districts, but in the younger children and in other districts it was higher. Between the two surveys there had been an increase in milk consumption and in the production of a forage crop, Chou Moellier or thousand-headed kale, one of the Brassicae.

The influence on the rate of accumulation of ^{131}I in the thyroid gland, of milk from cows fed on Chou Moellier compared with that of milk from cows not given kale, was studied for 10½ hr. after administration in single doses of 10 μC. to each of 5 girls aged 10 years and of 20 μC. to one adult subject, during which time they drank from 1½ to 3 pints milk. This and other tests showed that the milk from cows fed on Chou Moellier interfered significantly with the uptake of ^{131}I, suggesting that it contained an antithyroid substance, the nature of which is being investigated.

Muñoz, J. A., Perez, C. and Scrimshaw, N. S. El bocio endemico en Guatemala. [**Endemic goitre in Guatemala.**] *Bol. Ofic. sanit. panamer.*, 1955, **39**, 458–463. [Inst. Nutric. Centro Amér. y Panama, Guatemala.]

Clinical examination of 39,484 subjects in 3 areas of Guatemala showed an average of 38·5 per cent. with simple goitre. Seventy per cent. of the subjects examined were schoolchildren, 2 per cent. were under school age and 28 per cent. were adults. The sample included 1·4 per cent. of the population. The highest incidence of goitre was 65 per cent. in one island mountainous region, and incidence was high in other inland areas. Endemic goitre appears to be a serious public health problem in Guatemala and addition of iodine to salt is recommended. Since much of the salt used is unrefined, and the climate is damp, the use of potassium iodate is suggested.—A. M. Copping.

3750

Stuart, A. E. **The pathology of goitre in Tasmania.** *Med. J. Austral.*, 1955, i, 920–922. [Dept. Pathol., Launceston Gen. Hosp., Tasmania.]

Thyroid glands taken at 204 consecutive autopsies of 132 males and 72 females were weighed and examined histologically. Colloid and parenchymatous types of nodule were found. Of the females 18 and of the males 15 had multinodular glands, of which only about half were large enough to constitute a goitre when 70 g. was taken as the upper limit of weight of a normal gland. The histological appearance of what were considered to be early stages in goitre formation is described. Goitre material from Tasmania appeared not to differ from that from America or Switzerland. Experience with iodine prophylaxis led to the conclusion that simple dietary deficiency will not account for the prevalance of goitre in Tasmania. The occurrence of a natural goitrogenic agent is suspected.

3751

Greenwald, I. **Observations on the history of goiter in Ohio and in West Virginia.** *J. Hist. Med.*, 1955, **10**, 277–289. [Coll. Med., Univ. New York.]

This study, one of a series on the history of goitre, deals with aspects of the disease in Ohio, particularly along the shores of Lake Eire, and in West Virginia. The view that goitre was caused by a change from coarse unpurified salt to a more refined product has been re-examined and found to be untenable. It is claimed that goitre has almost disappeared and that there is no evidence that iodised salt had anything to do with this.

Turner, H. H. and Howard, R. B. **Goiter from prolonged ingestion of iodide.** *J. Clin. Endocrinol.*, 1956, **16**, 141–145. [Univ. Oklahoma Sch. Med., Oklahoma City.]

Seven boys and 6 girls between 5 and 17 years of age were treated for asthma with iodine as HI, KI or Lugol's solution for from 2 to 5 years. At the end of that time all had enlarged thyroid glands. When these drugs were replaced by desiccated thyroid the size of the thyroid decreased and signs and symptoms of hypothyroidism were less.

During treatment with I there was a slow uptake of ^{131}I. The uptake approached normal when iodides were omitted, although protein-bound I (PBI) in serum sometimes remained high. After 60 mg. desiccated thyroid had been given daily for 90 days there was a slight fall in ^{131}I uptake, but when desiccated thyroid had been discontinued for 5 weeks both the uptake of ^{131}I and the level of PBI were normal. It is suggested that this effect of iodides on thyroid size is a response peculiar to the thyroids of asthmatics. Three case histories are given.—B. W. Simpson.

3753

Bongiovanni, A. M., Eberlein, W. R., Thomas, P. Z. and Anderson, W. B. **Sporadic goiter of the newborn.** *J. Clin. Endocrinol.*, 1956, **16**, 146–152. [Dept. Endocrinol., Child. Hosp., Philadelphia 46, Pa.]

Case reports of 3 newborn infants are given. The possibility is discussed of the neonatal goitre being caused by iodides, sulpha drugs or thiouracil derivatives taken by the mother and transmitted across the placenta. In the absence of respiratory difficulties, the goitres of the infants diminished within a few days or weeks. If there was risk of death from asphyxia, subtotal thyroidectomy was preferable to tracheotomy.—B. W. Simpson.

3754

HOSTOMSKÁ, L., HORÁČKOVÁ, M., HRUBCOVÁ, M. and MALÝ, V. **Studies of the treatment of goiter in children without functional disturbances.** *Ann. paediat.*, 1955, **185,** 333–347. [2. Paediat. Clin., Charles Univ., Prague.] German and French summaries.

Children numbering 1931, between the ages of 3 and 15 years and without functional disturbance, were given thyroglobulin in amounts supplying from 250 to 1000 μg. organic I daily. Treatment lasted for from 1 to 5½ years, average 3 years. The results of treatment did not depend on sex or on the age at which it was begun; its duration was of much more importance. More goitres were cured or improved and fewer deteriorated the longer the period of treatment.

To assess its effects, children who had taken thyroglobulin for 4 years were compared with others who did not take it; all had iodised salt providing between 120 and 180 μg. I daily. For small goitres cure or improvement occurred in 70·6 and no change or worsening in 29·4 per cent. of the treated group with 194 children; corresponding values for the untreated group of 131 were 32·8 and 67·2 per cent., respectively. The findings for medium goitres were similar; the numbers with large goitres were too small to allow comparison.

There was evidence that the proportion of small goitres which remained unchanged was smaller in Prague than in the mountainous district of Sušice. The more numerous changes in Prague were both for better and for worse.—B. W. Simpson.

LEVY, R. P., KELLY, L. W. and JEFFERIES, W. M. **The effects of thyrotropin and desiccated thyroid upon hypothyroidism with goiter.** *Amer. J. Med. Sci.*, 1956, **231,** 61–68. [Dept. Med., Sch. Med., Western Reserve Univ., Cleveland, Ohio.] Interlingua summary.

3756

FRAWLEY, T. F., MCCLINTOCK, J. C., BEEBE, R. T. and MARTHY, G. L. **Metabolic and therapeutic effects of triiodothyronine.** *J. Amer. Med. Assoc.*, 1956, **160,** 646–652. [Subdept. Endocrinol., Albany Med. Coll., N.Y.]

Fourteen patients with myxoedema were studied to compare the therapeutic effects of DL-triiodothyronine hydrochloride, L-triiodothyronine, sodium L-thyroxine and desiccated thyroid. Each was effective in raising body temperature, accelerating pulse, increasing rate of oxygen consumption, decreasing bodyweight and reducing levels of cholesterol and carotenoids in blood. L-Triiodothyronine was about twice as active as DL-triiodothyronine and from 1½ to 2½ times as active as sodium L-thyroxine. The advantages and disadvantages of triiodothyronine are discussed.—F. C. Aitken.

WOLFF, J. A. and GOODFELLOW, A. M. **Haematopoeisis in premature infants with special consideration of the effect of iron and of animal-protein factor.** *Pediatrics*, 1955, **16,** 753–762. [Dept. Paediat., Coll. Phys. Surg., Columbia Univ., New York.]

Two groups of premature infants of birthweight less than 1200 g. and between 1200 and 1500 g. were subdivided into control and treated groups. In all, 81 infants were studied. Treatment consisted daily of 1 or 16 mg. Fe or 3 capsules of animal-protein factor, containing aureomycin 5, vitamin B_{12} 1·5 and Fe 0·3 mg. Treatment with Fe was begun within the first 10 days of life and with animal-protein factor before the 21st day.

Estimations of Hb, total counts of red cells, reticulocytes and platelets and differential counts of leucocytes were made and are tabulated for the first 12 weeks of life. In both groups, irrespective of birthweight, the lowest Hb value occurred about the eighth or ninth week; there was no evidence that degree of anaemia was related to birthweight. No treatment prevented or reduced the degree of anaemia during the first 3 months, but limited data for later months suggested that treatment with Fe prevented the occurrence of anaemia at 1 year of age.—F. C. Aitken.

3759

WINTER, S. T., MUNDEL, G. and SALOMON, H. **Intravenous iron therapy in anaemia in children.** *Ann. paediat.*, 1955, **185,** 362–368. [Rambam Govt. Hosp., Haifa, Israel.] German and French summaries.

Ten children with Fe-deficiency anaemia were successfully treated with a single massive dose of

saccharated iron oxide given by slow intravenous drip in a large volume of isotonic glucose solution. Side effects were slight.—F. C. Aitken.

3760

JHATAKIA, K. U. **Cobalt with iron in the treatment of iron deficiency anaemias.** *J. Indian Med. Assoc.*, 1956, **26,** 126–129. [Sir J. J. Hosp., Bombay.]

Twenty-five patients with anaemia, judged to require Fe, were treated with Fe and Co by vein. The types of anaemia, etiology, red cell count and Hb before and after treatment, the amounts of Fe and Co given during treatment and side reactions are tabulated. In most cases anaemia was microcytic hypochromic; in some it was normocytic hypochromic or macrocytic normochromic. The response to Fe with Co was better than in a previous series given Fe alone.

Thirty patients were treated. No difficulty was met in administration or from side effects, and treatment, as judged by haematological studies, was successful. Five case reports are presented.

F. C. Aitken.

3762

SCHLAGETTER, K. Die Bedeutung der Knockenmarksuntersuchung für die Diagnose der Anämien in der Geburtshilfe. [**The importance of study of the bone marrow for the diagnosis of anaemia in obstetrics.**] *Arch. Gynäkol.*, 1954–55, **185,** 641–674. [Frauenklin., Akad. Med. Forsch., Justus-Liebig-Hochsch., Giessen.]

A plea is made that, whenever the peripheral blood picture does not allow a clear differential diagnosis in anaemia of pregnancy and the puerperium, sternal puncture should be made. This should be a routine procedure in severe anaemia when Hb is 8 g. per 100 ml. or less.

The normal picture of the bone marrow in the last month of pregnancy is described. Descriptions and some illustrative case histories are given of the findings in Fe deficiency, infections, haemolytic icterus and megaloblastic anaemia of the puerperium. There are many references.

RAINER, O. and ZOLLNER, S. Die Anämien nach totaler Gastrektomie. (Versuche zur Prophylaxe und Behandlung.) [**Anaemia after total gastrectomy. (Attempts at prevention and treatment.)**] *Langenbecks Arch. klin. Chirurg.*, 1955–56, **281,** 371–381. [2. Med. Abt., Landeskrankenhaus, Klagenfurt.]

Anaemia occurred in 59 patients up to 4 years after total removal of the stomach. All had vitamin B_{12}, 30 μg. intramuscularly every fortnight, and the only patient who developed pernicious anaemia had omitted this treatment for 2 years. The others had hypochromic or normochromic anaemia of different degrees of severity, and a clinical picture of Fe deficiency. Absorption of Fe from Ferrogluconate in 5 patients, as estimated from the increase in serum Fe, was adequate. In patients with enteritis Fe was not absorbed in sufficient quantity and parenteral Fe was necessary. The signs of Fe deficiency appeared in the first year after operation in 35 of the patients; it is suggested that early treatment with Fe would have prevented most of this anaemia. Prophylactic doses of vitamins C and B complex are advised.—D. Duncan.

Some 75 to 85 per cent. of the patients in night sanatoria are active workers and the daily requirements are estimated to be 3500 to 4000 Cal., 120 to 140 g. protein, 115 to 135 g. fat and 500 to 550 g. carbohydrate. The special needs of the tuberculous worker are plenty of milk protein, methionine, calcium salts, some vegetable oil for lipotropic substances, Cu and vitamins. General principles for constructing diets suitable for these sanatoria are discussed.—D. Duncan.

Central, Madrid.] English, German and French summaries.

"Endogenous" causes of obesity are discussed. Case histories are given of 25 women and 4 men aged from 14 to 73 years. Nearly all had disturbed sexual function and nervous symptoms, and X-rays revealed a high incidence of hyperostosis in the cranium. Treatment was by diet, drugs which modified appetite, such as 2-phenyl-3-methyl-tetrahydro-1 : 4-oxazine, exercise, diuretics and psychiatric methods.—D. Duncan.

WEIL, M. H. **Polycythemia associated with obesity.** *J. Amer. Med. Assoc.*, 1955, **159,** 1592–1595. [Dept. Med., Med. Sch., Univ. Minnesota, Minneapolis.]

A form of polycythemia (defined by Hb value persistently above 19 g. per 100 ml.) occasionally found in obese persons is described, with 3 case histories. It differed from *polycythemia vera* in that there was no increase of immature cells, white cells or platelets in the peripheral blood, and the bone marrow was normal. Arterial oxygen saturation was only slightly depressed and cyanosis was absent. As weight was reduced by diet treatment, the Hb and haematocrit values returned to normal. The condition is considered to be secondary polycythemia produced by inadequate pulmonary ventilation resulting from deposits of fat in or about the thorax.—W. M. Deans.

TEREPKA, A. R. and WATERHOUSE, C. **Metabolic observations during the forced feeding of patients with cancer.** *Amer. J. Med.*, 1956, **20,** 225–238. [Dept. Med., Sch. Med., Univ. Rochester, N.Y.]

Nine patients with growing cancers underwent studies of energy, N, P, Ca, K, Na and Cl balance before, during and after periods of forced feeding with concentrated preparations by mouth, sufficient to raise energy intakes to the previously determined levels of energy expenditure.

Large gains of weight occurred during forced feeding, due in the main to accumulation of large quantities of intracellular fluid; afterwards loss of weight was rapid. There was transient benefit in a few, but in about half of the patients forced feeding did harm, as judged by significantly higher energy expenditure and basal metabolic rate and by clinical data.

The significance of the metabolic changes found is discussed.—F. C. Aitken.

SCHÖNENBERG, H., SCHMIDT, D. and WÖNCKHAUS, I. Der Phenylbrenztraubensäure - Schwachsinn. 12 eigene Beobachtungen. [**Mental deficiency and phenylpyruvic acid. Twelve new studies.**] *Ztschr. Kinderheilk.*, 1955, **77,** 363–383. [Kinderklin., Univ. Münster, Westf.]

Case histories are given of 12 patients with phenylpyruvic oligophrenia, aged from 1 to 52 years; 11 were found among over 3000 inmates of mental hospitals and 1 among over 2000 children in special schools. Only 8 of them were blond, and other physical pecularities were such as are common in other types of mental defect; the only distinctive sign was the high phenylalanine content of blood and urine. Excretion of other amino acids was not remarkable and varied greatly between individuals. There was no mental improvement in 2 treated with large amounts of vitamin C, daily for 4 weeks 2 ml. Cebion forte intramuscularly or 5 ml. Vitamin C forte intravenously; in 1 of these *l*-tyrosine, 30 mg. per kg., was likewise of no effect, nor did it reduce the phenylalanine content of blood or urine.—W. M. Deans.

COLBOURNE, M. J. (with SOWAH, E. M. A.) **Does milk protect infants against malaria?** *Trans. Roy. Soc. Trop. Med. Hyg.*, 1956, **50,** 82–90. [Gold Coast Med. Serv., Accra.]

African infants born in Accra were studied closely for the first 6 months of their lives during the malaria season. There were 2 groups, one of 27 given a yeast tablet with 3 mg. *p*-aminobenzoate daily to test its efficacy in preventing infection and the other of 28, intended as a control group and given 0·5 ml. cod liver oil daily as a placebo. Treatment began at age between 2 and 4 weeks. Records were kept of the times at which the change from breast to mixed feeding was made; over the 6-month period records were complete for 39 infants, 17 in the yeast and 22 in the control group. Of these, 23 acquired malaria, 12 in the yeast and 11 in the control group.

In the control group positive slides were found in 7 before mixed feeding began. An early beginning to it did not, from the small numbers available, appear to increase susceptibility.

In the yeast group slides were positive in 9 before the start of mixed feeding and, from the fourth to the sixth months, it seemed that this group was the more susceptible. Estimations of *p*-aminobenzoate in samples of milk from 10 mothers showed, on the average, only minute amounts, free 44·6 μg. and total 92·6 μg. per litre. In these infants the yeast with its *p*-aminobenzoate seemed to have facilitated rather than prevented infection.—D. Harvey.

KLEIBER, M. Rückwärts oder vorwärts vom Stärkewert? [**Backwards or forwards from starch equivalent?**] *Schweiz. Landwirtsch. Monatsh.*, 1956, No. 1, Sonderheft 60. Geburtstag Prof. Crasemann, 6–9. [Div. Animal Husb., Univ. California, Davis.]

It is contended that the "Kellner unit" based on net energy, suggested by Fuchs and modified by Nehring (Abst. 2816, Vol. 25), is not an improvement on starch equivalent and the name is misleading. Net energy is useful for comparing the efficiency of different processes, *e.g.*, of fattening cattle with that of fattening pigs; starch equivalent for comparing the nutritive value of one feed with that of another. For the second purpose, going back to net energy represents a failure to recognise Kellner's advance on Armsby's method, and a misguided striving after "absolute" standards. On the other hand, as has been shown by the present author and colleagues (Title 4978, Vol. 16; *Hilgardia*, 1945, **16,** 511) for chickens and dairy cows, the principle of equivalents can be extended by using as reference, instead of starch or barley, a mixture of glucose and casein adjusted so as to have the same protein ratio as the feed under test. For example, for milk production 1 kg. barley is equivalent to 1 kg. glucose plus 90 g. casein.—W. M. Deans.

3790

GEERING, J. and BACHMANN, F. Beitrag zur Rauhfutterbewertung. [**Estimating the value of roughage.**] *Schweiz. Landwirtsch. Monatsh.*, 1956, No. 1, Sonderheft 60. Geburtstag Prof. Crasemann, 32–36. [Eidg. Landwirtsch. Versuchsanst., Zürich-Oerlikon.]

This is a preliminary report on work it is hoped to publish in fuller detail later. In the hope of finding useful correlations between the starch equivalent of a roughage and some chemical constituent, 22 samples of hay, aftermath and dried grass of very varied quality, which had been used in digestibility experiments with sheep at the *Institut für Haustierernährung*, and the corresponding faeces, were analysed.

The best inverse correlations ($r^2 = 0{\cdot}88$, 0·87) were with material insoluble in hot dilute (1·75 per cent.) HCl and with the lignin content of the dry matter; the next best was with crude fibre by

the Weende method. The corresponding regression equations are given. Close inverse correlations ($r^2 = 0{\cdot}92$, $0{\cdot}87$) were also found between lignin content and percentage digestibility of organic matter or of crude protein, and the regression equations are given. A test with pea pods and millet chaff indicated that the regression equation for starch equivalent on lignin, but not that on crude fibre, might be applicable to other types of roughage, but further investigation is required.—W. M. Deans.

3791

HÜNI, K. Die näherungsweise Berechnung des Futterwertes von Mischfutter. [**Estimation of the approximate feeding value of a mixed ration.**] *Schweiz. Landwirtsch. Monatsh.*, 1955, No. 6, pp. 4. [Eidg. Agrikulturchem. Versuchsanst., Liebefeld-Berne.]

Calculation of the approximate composition was possible when mixed rations were made up according to certain principles: a mixture must contain no component feedingstuff not digestible by the species for which it was intended; components with good digestibility but a high crude fibre content should not make up more than 10 per cent. of the ration; oilseed residues should be used as extraction products, except that 10 per cent. linseed cake could be used; supplements such as cod liver oil and minerals were not included in the calculation; and a good range of crude fibre contents allowed most accurate calculations.

For 165 mixed rations the protein content, digestible crude protein, crude fibre and value in starch units (or for birds the total nutrients) were calculated from the latest Swiss tables of composition, and by the method of multiple regressions was obtained the formula

$$VK_E = 78{\cdot}8 + 0{\cdot}39\ E - 0{\cdot}44\ Rfs,$$

where VK_E is the coefficient of digestibility of crude protein, E the crude protein and Rfs the crude fibre as percentages of the mixture. This formula applied to mixtures within the ranges of 10 to 34 per cent. crude protein and 3 to 15 per cent. fibre.

Regressions are tabulated for the relations between starch units or total nutrients and crude fibre for rations intended for different classes of stock.—D. Duncan.

3792

HÜNI, K. Die Verdaulichkeit und der Futterwert von Weizen und Roggen und der davon anfallenden Müllereinebenprodukte. [**Digestibility and feeding value of wheat and rye and their milling offals.**] *Landwirtsch. Jahrbuch Schweiz*, 1955, **69**, 961–964. [Eidg. Agrikulturchem. Versuchsanst., Liebefeld-Berne.] French summary.

The results of 138 digestibility trials, namely, 60 with wheat products on ruminants and 39 on pigs and 30 with rye products on ruminants and 9 on pigs, were examined statistically.

The regressions of digestibility of crude protein (VK_E) on crude fibre content on a 12 per cent. moisture basis (Rfs) did not differ significantly for ruminants and pigs or for wheat products and rye products, and the "mean" regression equation

$$VK_E = 89{\cdot}4 - 1{\cdot}52\ Rfs,\ r = -0{\cdot}670,$$

is considered satisfactory for general use.

No connection between crude fibre content and digestibility of fat or of crude fibre was found; respective mean values of 70 and 34 per cent. may be used. Digestibility of N-free extract fell as crude fibre content rose; the "mean" regression equation was

$$VK_E = 97 - 2{\cdot}66\ Rfs,\ r = -0{\cdot}860.$$

No connection was found between crude fibre content and Kellner's "value" (*Wertigkeit*); until the position is cleared up, the use of Axelsson's formula (Abst. 2915, Vol. 8)

$$\text{"value"} = 99{\cdot}0 - 0{\cdot}515\ Rfs - 0{\cdot}026\ (Rfs)^2$$

is suggested.

From these results the regression equation for starch units (StE) is derived, namely,

$StE = 82{\cdot}8 - 3{\cdot}29\ Rfs + 0{\cdot}034\ (Rfs)^2$, $r = 0{\cdot}997$.

For crude fibre contents between 3 and 12 per cent. the linear equation

$$StE = 81{\cdot}5 - 2{\cdot}78\ Rfs$$

suffices.—W. M. Deans.

3793

HÜNI, K. Beziehungen zwischen dem Rohnährstoffgehalt und der Verdaulichkeit von Mais und Nebenprodukten der Maisvererbeitung. [**Relation between content of nutrients and digestibility of maize and maize milling offal.**] *Schweiz. Landwirtsch. Monatsh.*, 1956, No. 1, Sonderheft 60. Geburtstag Prof. Crasemann, 29–31. [Eidg. Agrikulturchem. Versuchsanst., Liebefeld-Berne.]

On the basis of 34 digestibility trials with maize and maize products on ruminants reported in Schneider, "Feeds of the World, their Composition and Digestibility" (Abst. 4061, Vol. 17), equations like those in the preceding Abst. were derived.

Digestibility of crude protein (VK_E) rose with crude protein content on 10 per cent. moisture basis (E); the regression equation was

$$VK_E = 45{\cdot}6 + 2{\cdot}27E - 0{\cdot}03E^2,\ r = 0{\cdot}795,$$

or, for crude protein contents between 5 and 35 per cent.,

$$VK_E = 57{\cdot}0 + 0{\cdot}94\ E,\ r = 0{\cdot}764.$$

In maize no connection was found between digestibility of crude protein and crude fibre content.

Digestibility of fat depended on the fat content (F) and the regression equation was cubic:

$$VK_F = 12{\cdot}4 + 25{\cdot}20\ F - 2{\cdot}64\ F^2 + 0{\cdot}09\ F^3;$$

but for maize itself and maize products with 5 per cent. crude fat or less, a mean digestibility coefficient of 74 per cent. can be used.

No connection was found between digestibility of crude fibre and content of any nutrient; the mean value was 49 per cent.

Digestibility of N-free extract satisfied the regression equation

$$VK_{Nfr} = 91{\cdot}8 - 0{\cdot}79 \text{ Rfs}, r = 0{\cdot}626.$$

Finally, starch units were given by the formula

$$StE = 75{\cdot}0 + 1{\cdot}40 F - 1{\cdot}49 \text{ Rfs}.$$

W. M. Deans.

3794

JONES, A. R., BEZEAU, L. M., OWEN, B. D. and WHITING, F. **The effects of mould growth on the digestibility and feeding value of grains for swine and sheep.** *Canad. J. Agric. Sci.*, 1955, **35,** 525–532. [Div. Animal Husb., Exp. Farms Serv., Canada Dept. Agric., Ottawa, Ont.]

In digestibility studies with pigs each weighing 60 to 70 lb., the organic matter, protein, N-free extract and gross energy of No. 1 feed oats were digested to a greater extent than those of 2 samples of mouldy oats. There were 65 per cent. total digestible nutrients (T.D.N.) in No. 1 feed oats, but only 54 and 59 per cent. in the mouldy oats. The mouldy oats weighed less per bushel, had slightly less protein and 4 to 5 per cent. more crude fibre than the feed oats. The organic matter, protein and gross energy of mouldy wheat were more highly digestible than in No. 5 wheat, and the T.D.N. rose from 76 to 79 per cent. The mouldy wheat contained 1 per cent. more protein and 0·5 per cent. less crude fibre than the non-mouldy sample and doubt is expressed whether the 2 lots would have been of the same quality before mould growth took place.

In a feeding trial with pigs, growth rate and efficiency of feed conversion were not affected when mouldy oats replaced feed oats included as 25 and 36 per cent. of rations given before and after 110 lb. bodyweight, respectively. It was considered that the differences in feeding value of mouldy and non-mouldy oats may have been masked by other ingredients in the ration. The replacement of No. 5 wheat with mouldy wheat did not affect rate of growth or efficiency of feed conversion in the feeding trial.

The organic matter, protein and energy content of No. 1 feed oats were digested better than those of mouldy oats by 9-month-old lambs. The feed oats and mouldy oats yielded 71 and 64 per cent. T.D.N., respectively.

No. 1 feed oats or mouldy oats were given along with hay in a feeding trial with 45 lambs. Average daily gains and efficiencies of conversion were less when mouldy oats constituted 50, 75 or 100 per cent. of the grain ration.

In the experiments reported mouldy oats and mouldy wheat were both palatable.—I. A. M. Lucas.

3795

SOLUN, A. S. Kukuruza-vazhneishaya kormovovya kul'tura. [**Maize as fodder.**] *Veterinariya*, 1955, **32,** No. 10, 69–73. [Moscow Vet. Akad.]

3796

AMBO, S., MASUBUCHI, T., HASHIZUME, T., ABE, M. and KURATA, Y. [**Digestion trials of feeds with Japanese native cattle.**] *Bull. Nat. Inst. Agric. Sci., Chiba, Japan* [*G*], 1955, No. 11, 233–245. In Japanese: English summary, 246–247.

Digestion trials with mature Japanese native cows are reported. Cocksfoot and red clover hay, 2 samples of wild grass hay, rice bran oil feed, rice straw and a mixture of wild grass hay 3 parts, rice straw 2 parts and wheat bran 1 part were investigated. Tables are presented of the composition, percentage digestibilities of the constituents, and total digestible nutrients of the feeds. The rice bran oil feed had 19 per cent. crude protein of digestibility 62 per cent. Rice straw had a low feeding value. The mixture of feeds had 4·01 per cent. digestible crude protein and 42·28 per cent. total digestible nutrients. In digestible crude protein and total digestible nutrients it was inferior to the hays.—T. D. Bell.

3797

LENNERTS, L. Steigende Gaben von Stroh als Ersatz für Heu in ihrem Einfluss auf die Verdaulichkeit des Gesamtfutters nach Versuchen an Schafen. [**Increasing amounts of straw as substitute for hay and their effect on the digestibility of the whole ration in experiments with sheep.**] *Arch. Tierernährung*, 1955, **5,** 348–367. [Inst. Tierernährungslehre, Humboldt. Univ., Berlin.]

With a view to elucidating the effect of straw, given as a substitute for hay, on the digestibility of the ration, 6 preliminary 10-day trials were made with 2 Merino wethers of mutton type weighing between 85 and 90 kg. In successive trials they were fed on hay alone, straw alone or 3 : 1, 1 : 1, 2 : 3 or 1 : 3 mixtures. The hay was of medium quality; the dry matter contained organic substance 93·6, crude protein 10·8, crude fat 2·1, crude fibre 31·3, N-free extract 49·4 per cent. The straw was mainly oat with a little rye: organic substance 91·3, crude protein 5·4, crude fat 1·5, crude fibre 43·9, N-free extract 40·3 per cent. Both were chopped. The sheep were fed twice daily; the total amount given in all the trials was 1000 g., an amount previously found

suitable (Abst. 5744, Vol. 25), but sheep 1 failed to eat it all, especially straw. Water was always available.

The results are tabulated, analysed and discussed in detail, but were not all concordant for the 2 animals. In sheep 1, digestibility of crude protein was reduced by admixture of straw, but not significantly until 750 g. straw was given; sheep 2 showed a non-significant reduction at this level. The effect on digestibility of crude fibre was small. Results for crude fat were inconclusive. Digestibility of N-free extract was reduced in sheep 1, but not in sheep 2, by admixture of straw.—W. M. Deans.

3798

HORN, V. and ESAT-KADASTER, I. (with KANSU, S.) Futterwert der Vicia ervilia in grünem Zustand und als Heu, Stroh und Samen. [**Feeding value of *Vicia ervilia* in the green state, as hay, straw and seeds.**] *Turk. Gen. Kim. Kurumu Dergisi* [*B*], 1952, **6**, 31–46. [Inst. Agric. Chem., Landwirtsch. Fak., Ankara.]

This paper consists largely of tables of the composition and feeding value for sheep of *Vicia ervilia* (bitter vetch, in Turkish, burçak), as green plant, hay, silage, seeds and straw, based on experiments of which some date back before the war. The plant is probably a native of Anatolia. It is less sensitive to drought and frost than the common vetch (*Vicia sativa*) and occupies nearly 30 per cent. of the land devoted to leguminous plants in Turkey, 3 times as much as the common vetch. Annual statistics of production are given for the years 1928 to 1954. The seeds are an important concentrate, especially for working oxen and buffaloes. When not irrigated the plant is so low that it is harvested by pulling out by the roots, and average yield is low, 700 to 800 kg. seeds per hectare.

In experiments [scale not stated] the green plant or hay gave about 380 kg. crude protein per hectare, and almost twice as much when grown as a catch crop on irrigated land; seeds gave 235 and straw 53 kg. crude protein per hectare. The hay was almost as digestible as the green plant; it contained as much protein as alfalfa hay and had a considerably higher starch equivalent. The straw, on the other hand, was a poor feed. Silage, made under makeshift conditions in petrol containers, was not entirely satisfactory and the sheep took some time to get used to it, but was sufficiently promising to justify further investigation. No ill effect occurred, but the literature suggests that for non-ruminants caution is required. As with bitter lupins, the risk can be avoided by steaming and washing the seeds with hot water.

W. M. Deans.

DAS, B. K., MUKHERJEE, N. C. and SEN, B. **Studies on black gram as a concentrate cattle feed.** *Indian J. Vet. Sci.*, 1955, **25**, 329–334. [Animal Nutrit. Res. Scheme, Gauhati, Assam.]

The seeds of black gram (*Phaseolus radiatus*) had the following percentage composition on a dry matter basis: crude protein 23·6, ether extract 1·3, ash 4·2, crude fibre 5·8, N-free extract 65·0, Ca 0·2, P 0·55. In trials with Assam bullocks, digestibility coefficients were: dry matter 65, crude protein 57, ether extract 52, crude fibre 82, N-free extract 67, total carbohydrate 68. Digestible protein was 12·5 lb. and starch equivalent 55·77 lb. per 100 lb. During the experiment the bullocks were in positive P and N balance but showed a negative Ca balance.—J. S. Thomson.

OLSSON, N. and OLOFSSON, N. E. Försök rörande fiskprodukternas tillvaratagande och användbarhet som foder. [**Investigations concerning preservation of fish products and their use for feeding.**] *Kgl. Lantbrukshögsk. Statens Husdjursförsök Medd.* No. 59, 1955, pp. 38. English summary.

Wet conservation of fish with acid or molasses is described. Fish should be fresh and should be crushed or milled before the preserving fluid is added; the mixture should be stirred daily till fermentation stops (about 14 days); the temperature should not rise above 15° C. Per 100 kg. fish the quantity of acid to be added increases with the ash content of the fish from 4·5 litres A.I.V. fluid or 1·35 litre formic acid, 23·5 *N* [for corrected quantities refer from p. 7 to inside front cover]; the amount of molasses required is independent of the ash content of the fish and is 20 kg. per 100 kg. fish.

Experiments were made in which fish silage was compared on a dry matter basis with fishmeal made from the same raw fish, and with skimmed milk (pigs only) as a supplement to the usual cereal rations for chicks and pigs. Chicks with 7 per cent. fishmeal grew faster and made more economic weight gains than those with fish silage; formic acid silage came next with male birds and A.I.V. silage with hens. Results were similar with pigs. Fish in either form gave softer back fat than skimmed milk; a tasting panel was not agreed on fishy taste in the bacon.

Silage making is recommended only where the catch of fish is small and the distance from a drying plant too great to justify the cost of transport. Maximum daily quantities [inside front page] are given as 0·5 kg. white fish or 0·3 kg. fat fish, fresh or ensiled, or 0·15 kg. fishmeal for pigs and 25 or 5 g. for laying hens. Fattening pigs should have no fish after 40 kg. weight and

table poultry none during the last 2 weeks before killing, or 4 weeks for ducks and turkeys.

In trials with rats, poultry, lambs and steers no ill effect resulted from the feeding of biuret. Lambs given biuret appeared to drink more water than lambs given urea. Lambs and steers given biuret had poorer appetites and steers made poorer gains than those fed on urea and feed protein, but this could be overcome by adding adequate protein from cottonseed meals or higher levels of urea to the biuret ration. It is concluded that biuret is not a dependable source of nitrogen for ruminants.

WATKINS, W. E. and KEARNS. J. V. (JR.) **The nutritive value of various grasses and grass-legume mixtures.** *J. Animal Sci.*, 1956, **15,** 153–162. [New Mexico Agric. Exp. Stat., State College.]

Data are given for the chemical composition, digestibility and total digestible nutrients, determined with wethers, of western wheat grass, crested wheat grass, coastal Bermuda, and mixtures of coastal Bermuda and alfalfa, and Alta fescue with ladino clover. Some of the grasses were at different stages of growth. All the grasses and mixtures when harvested immature provided palatable and nutritious fodder, high in digestible nutrients. Coastal Bermuda, alone or with alfalfa, when harvested mature, was not so palatable and had a lower content of digestible nutrients. There was a correlation of + 0·84 between the lignin and crude fibre contents of the grasses. Negative calcium balances were obtained with a mixture of old and new crested wheat grass and with Bermuda grass, and negative nitrogen balances with coastal Bermuda mixed with alfalfa. Data are given also for vitamin A, Ca and inorganic P in blood plasma.

DIJKSTRA, N. D. and VAN DER SCHAAF, D. Onderzoek naar de voederwaarde van gebroeid hooi. [**The feeding value of heated hay.**] *Versl. Landbouwk. Onderzoek.*, 1955, No. 61·15, pp. 33. English summary.

Sixteen samples of hay, normal or heated, from 6 stacks were analysed, digestibility was estimated *in vitro* with pepsin and HCl or with wethers, and the degree of heating was estimated in terms of "heating colour" (broeikleur) as follows: 1 g. of finely ground or cut hay was boiled under reflux for 5 min. in a 5 per cent. solution of sodium carbonate. After cooling the extract was filtered,

diluted with 4 parts of water and compared in a Beckman spectrophotometer with a blank solution of 1 per cent. soda. The optical density × 1000 is the index of colour. The results are presented in tables and shown in diagrams. Digestibility of organic matter was not much affected but that of protein decreased greatly and in close relation to the heating colour. Loss of starch equivalent, too, was closely related to colour. The difference between digestibility *in vitro* and *in vivo* also changed with colour.—I. Leitch.

ORGANISATION FOR EUROPEAN ECONOMIC CO-OPERATION. **Pasture and fodder production in North-West Europe.** *Technical Assistance Mission*, No. 123. 2, Rue André-Pascal, Paris 16, 1954, pp. 177.

The countries covered in this report are Austria, Belgium, Denmark, France, Western Germany, Ireland, Northern Italy, the Netherlands, Norway and the United Kingdom. In part 1 the geographical and climatic features of the area are surveyed. Grassland is of great importance for the large livestock population and to maintain soil fertility. The total net productivity of the grasslands has been estimated from the difference between the calculated total feed requirements of all farm livestock and the total feed supplied by all other categories of feedingstuffs. Estimated outputs expressed as thousand fodder units per hectare (1 fodder unit = 0·7 kg. starch equivalent) vary from 2·0 for France through 3·0 (16·7 cwt. starch equivalent per acre) for the United Kingdom to 4·7 for the Netherlands. Target figures are given to provide " a realistic picture of the magnitude of the increased productivity which can be expected through the improvement of the existing area under grass, clover and lucerne in Western Europe ". The increases suggested vary from 17 to 18 per cent. for the Netherlands and Norway, through 33 per cent. for the United Kingdom to 50 to 60 per cent. for France and Ireland with a mean increase of 42 per cent., equivalent to 44 million tons fodder units. General recommendations are made for obtaining these increases. They include studies of fertiliser practice and irrigation, herbage species and seeds mixtures, methods of grazing management, conservation methods, estimation of nutritive values, conditions influencing animal health, advisory work and international cooperation for the exchange of technical information and workers. The report stresses that there is " a general need for the awakening in each country of a proper appreciation of the value of grasslands and for a realisation of the importance of grassland improvement work in promoting the general economic wellbeing and in raising general living standards ". In part 2 the countries are considered individually, their particular features are discussed and specific recommendations are made.—J. L. Corbett.

FURRER, O. J. Silagebereitung und Silagefütterung in der Schweiz. [**The making and use of silage in Switzerland.**] *Schweiz. Landwirtsch. Monatsh.*, 1956, No. 1, Sonderheft 60. Geburtstag Prof. Crasemann, 89–92. [Inst. Haustierernährung, Eidg. Tech. Hochsch., Zürich.]

Statistics are quoted from an inquiry in the winter of 1954–55 covering 1400 farms all over Switzerland, made by the *Institut für landwirtschaftliche Betriebe* of the Eidgenössische Technische Hochschule, Zürich (Furrer, *Agrarpolitische Revue*, 1955, **11,** 330).

On about 44 per cent. of the farms the use of silage was not permitted because cheese was made all the year round. Among the others, silage was more often made on large farms than on small and for the Pied Mountain than for the Swiss Brown breed. The commonest crops ensiled were grass and clover and mixtures, followed by maize and beet leaves and slices, and the commonest preservatives were formic acid and A.I.V. fluid ; fruit and fruit residues were sometimes added. The amounts given varied greatly, average 11·8 kg. daily for Brown cows and 15·1 for Pied cows. It is estimated that 320,000 tons a year are made in Switzerland, enough for the production of 150 million kg. milk, and that, compared with ordinary haymaking, about 15 million starch units, worth 10 million francs, are saved.—W. M. Deans.

NELSON, A. B., BRATCHER, G., HUMPHREY, R. D. and MACVICAR, R. W. **Creep-feeding spring calves.** *Oklahoma Agric. Exp. Stat. Bull.* No. B-462, November 1955, pp. 20.

Trials made over 3 years with 197 Hereford calves showed that calves which were creep-fed gained on the average 30 lb. more in liveweight up to weaning than those which were not creep-fed. When creep feeding was followed by dry-lot fattening it proved to be less profitable than feeding in the normal way. The addition of molasses to a creep feed consisting of yellow maize, oats and cottonseed meal improved consumption but reduced profit.—J. N. Aitken.

FLUX, D. S. and PATCHELL, M. R. **The use of dried buttermilk as a feed for dairy calves.** *N.Z. J. Sci. Technol.* [*A*], 1956, **37,** 451–457. [Dairy Res. Inst. (N.Z.), Palmerston North.]

Reconstituted buttermilk, prepared from 2 types of dried buttermilk containing 16 and 8 per cent. fat, was given to 32 calves at the rate of 10 and 12½ per cent. of bodyweight. Whole milk was given until the calves were 4 weeks old and then gradually replaced with reconstituted buttermilk so that only the latter was given from 6 to 10 weeks of age. The calves grazed high-quality pasture throughout the experiment. The weight gains from 4 to 10 weeks were significantly higher ($< 0{\cdot}05$) for calves on the high level than in those on the low level of milk consumption; differences between weight gains of calves given the 2 types of dried buttermilk were in favour of the high-fat diet but were not significant.

A regular supply of drinking water is of particular importance for calves during the weaning period, also succulent fodder of silage, beet and potatoes. A mineral supplement is necessary when silage is given.—H. Scherbatoff.

3822

DAVIS, H. P. **Growth comparisons for Holstein, Ayrshire, Guernsey and Jersey males for the first six months of life.** *Zootec. Vet.*, 1956, **11,** 65–69. [Univ. Nebraska.]

Records of monthly measurements of all male calves born into the University of Nebraska herd during 20 years are presented. The measurements include weight, heights at withers, hooks and pin bones, length of body and rump; widths at hooks, chest and pin bones; depths of chest and barrel and skin thickness at the fore and last rib. The numbers of animals were: at birth, Holsteins 220, Ayrshires 58, Guernseys 25 and Jerseys 95: at 6 months, Holsteins 104, Ayrshires 12, Guernseys 8 and Jerseys 31. Holsteins were heavier at birth and the difference was still apparent after 6 months. The overall growth rate of Ayrshires was slower and that of Jerseys faster than that of the other breeds.—J. N. Aitken.

DELAGE, J., POLY, J. and VISSAC, B. Étude de l'efficacité relative des diverses formules de barymétrie applicables aûx bovins. [**The relative efficiency of different barymetric formulae applicable to cattle.**] *Ann. Zootech.*, 1955, **4,** 219–231. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

The value of coefficients which enable the bodyweights of cattle to be estimated from measurements is discussed. Measurements were made on 201 cattle of 3 breeds, Norman, French Friesian and Eastern Red Pied. For bulls of all 3 breeds the highest correlations with bodyweight were obtained with chest girth and spiral girth. The spiral girth is measured from the tip of the sternum, the tape passing to the back in the lumbar region and over the opposite side of the rump to below the perineum. The regression coefficients of bodyweight on these measurements and their arithmetic mean were higher in males than in females in all 3 breeds. Standard deviations in estimation of liveweight from these regression lines were from 3·9 to 8·6 per cent. The chest girth gave the greatest precision. Regression values for liveweight and chest girth are given for all 3 breeds and both sexes, on the basis that all the cattle weighed at least 450 kg. and were in show condition. A linear equation was more accurate for cows and a curvilinear equation for bulls. The accuracy in each case was about 5 or 6 per cent. With larger numbers of animals the error may be reduced.—D. Duncan.

3825

EKTOV, V. A. Vliyanie urovnya pitaniya na izmenenie kreposti kostei u molodnyaka krupnogo rogatogo skota. [**Influence of nutritional standards on changes in bone strength in young cattle.**] *Zh. Obshchei Biol.*, 1954, **15,** 188–191. [Dept. Breeding Agric. Animals, Timiryazev Agric. Acad.]

One of the principal indices of a strong constitution in animals is a strong, well developed bony skeleton. An investigation was initiated into the changes in the bone structure of cattle in relation to age and nutritional standards. There were 3 groups in the experiment: "ample", "poor" and "transitional" feeding. This last group after being fed on the ration of the second group for 6 months was transferred to the first group. During the experiment, from birth to 18 months, the first group received in all 2653 feed units and 297 kg. digestible protein, the second 1720 feed units and 147 kg. digestible protein and the third 2403 feed units and 260 kg. digestible protein. During the same period the first group received 26·87 kg. Ca and 15·53 kg. P, the second 19·06 kg. Ca and 7·45 kg. P and the third 24·38 kg. Ca and 14·53 kg. P.

With improved feeding it was found that strength of bone increased greatly, particularly of the shoulder-blade, metatarsus and metacarpus, but the strength of bone in the lower jaw was less than in animals on poor feeding, particularly on coarse fodder. In animals in the third group bone strength was somewhat restored by transfer to a more ample ration, but did not attain the level of bone of animals on ample rations from birth.

NORDFELDT, S. Försök med uppfödning av gödkalvar. [**Experiments in the feeding of veal calves.**] *Kgl. Lantbrukshögsk. Statens Husdjursförsök Särtryck* No. 112, 1955, pp. 16.

Tests were made between 1952 and 1955 with Holstein, SRB and SKB calves, given ordinary milk for the first 4 days and then increasing quantities to age 31 (Holstein) or 37 days of milk of reduced fat content, with a concentrate mixture of grain, linseed cake meal and dicalcium phosphate and some hay. Those given skimmed milk got 10 g. cod liver oil daily from 31 days to slaughter at 85 kg. liveweight. At one centre 3 SRB and 3 SKB calves were given ground linseed in skimmed milk.

The Holstein, bull, calves were heavier at birth, about 46 kg., the SRB were about 37 kg. and the SKB 32 to 34 kg. Rate of weight gain and grading for fat decreased with the fat in milk and loss at slaughter increased. Feed units per kg. gain in weight also fell with percentage fat in milk. *e.g.*, from 2·59 for Holsteins getting milk with 3·8 per cent. fat to 2·16 for those getting milk with 1·8 per cent. fat.

The economics of such production are discussed in detail in relation to type of calf, prices for veal in south, middle and north Sweden and type and cost of milk. At prices ruling when the tests were made the Holsteins on skimmed milk (with some whole milk to 30 days of age) were most profitable and those on 1·8 per cent. milk next. Production was least profitable in north Sweden where milk prices were highest, and SKB calves were less profitable than SRB.—I. Leitch.

3828

KIDWELL, J. F. and MCCORMICK, J. A. **The influence of size and type on growth and development of cattle.** *J. Animal Sci.*, 1956, **15,** 109–118. [Dept. Animal Husb., Univ. Nevada, Reno.]

Growth, feed efficiency and carcase characteristics of Holstein and Hereford steers were compared, the two breeds being reared under different dietary regimes. The Holstein steers made weight gains faster and more efficiently, and at slaughter produced carcases having more bone, more muscle and less fat, than did Hereford steers. On the basis of these data, the validity of using rate and economy of gain as selection criteria for beef cattle is discussed in relation to type and size of such animals at maturity.—T. R. Preston.

3829

NELSON, A. B., GALLUP, W. D., ROSS, O. B. and DARLOW, A. E. **Supplemental phosphorus requirement of range beef cattle in north central and southeastern Oklahoma.** *Oklahoma Agric. Exp. Stat. Tech. Bull.* No. T-54, July 1955, pp. 29.

Trials were made over 4 years on 2 areas in Oklahoma; one in the north central area (Stillwater) where there was borderline deficiency of P in soil and the other in the south-east (Wilburton) where the soils were definitely deficient. Both areas were stocked with 30 in-calf Hereford heifers and 30 weaned calves. On each location both age groups of cattle were divided into 3 groups of 10 animals each. The only source of P for cattle of both ages in group 1 was native grass hay and a protein supplement in winter and pasture grass in summer. The cattle in group 2 were given dicalcium phosphate in amount to provide 1·5 g. P per 100 lb. liveweight. In summer those at Wilburton were allowed access to a mineral mixture. Those at Stillwater received no additional P in summer. The animals in group 3 received P at the rate of 2·5 g. per 100 lb. liveweight in winter and were allowed access to a salt lick in summer. Winter feed for all consisted of grass hay grown on land adjoining the experimental areas.

Results from the Stillwater area (marginal P deficiency) showed that there was some benefit from the P supplements as measured by growth of the calves, weight changes of the cows, reproductive performance and plasma P values. It was estimated that the minimum requirement of P for cows managed in the way described was 7 g. daily in winter, 9 g. in early summer and 6 g. in late summer. It is recommended that in this area in years in which there is poor growth of grass additional P should be provided. In the Wilburton area (P deficiency) P supplements greatly improved growth of calves and heifers. Benefit to the cows could not be clearly demonstrated because of other unknown complications. It was estimated that the minimum P requirement of cows in this area is 7 g. daily. It is recommended that P supplements should be given at all times to cattle in this area.—J. N. Aitken.

BENTLEY, O. G., KLOSTERMAN, E. W. and ENGLE, P. **The use of urea to increase the crude protein content of corn silage for fattening steers.** *Ohio Agric. Exp. Stat. Res. Bull.* No. 766, November 1955, pp. 20.

Urea mixed with maize as the silo was filled increased the N and digestible crude protein content of the silage, as estimated by chemical analyses and digestibility studies with sheep. Most of the added N was retained, generally as ammonium salts of the organic acids normally present in maize silage. Feeding trials with young fattening cattle showed that silage made with urea was a safe and palatable feed and produced more economical liveweight gains than conventional rations of maize silage and soya bean oilmeal.

T. R. Preston.

MEYER, J. H., LOFGREEN, G. P. and ITTNER, N. R. **Further studies on the utilization of alfalfa by beef steers.** *J. Animal Sci.*, 1956, **15,** 64–75. [Dept. Animal Husb., Univ. California, Davis.]

In 2 experiments to compare beef production from alfalfa in 5- to 7-day rotational grazing, strip grazing, haymaking or soiling (cut and given green), similar liveweight gains were made on forage grazed or given as soilage; significantly lower gains were made on forage given as hay. More dry matter was consumed per 100 lb. gain when alfalfa was given as hay then as soilage; consumption was least for alfalfa grazed *in situ*. Amounts of beef produced per acre, expressed as percentages of the soilage group, were 77, 79 and 85 in experiment 1 and 64, 68 and 79 in experiment 2, for rotational grazing, strip grazing, and haymaking, respectively. There was a greater incidence of bloat among strip-grazed steers than in any of the other groups.—T. R. Preston.

KIRK, W. G. and DAVIS, G. K. **Citrus products for beef cattle.** *Florida Agric. Exp. Stat. Bull.* No. 538, January 1954, pp. 16.

The citrus products are described, and trials in which they have been successfully used in combination with hay or pasture and cottonseed meal for fattening beef cattle are briefly reported.

Fresh grapefruit unsuitable for market are readily eaten by cattle, but oranges are not so palatable, a difficulty partly overcome by grating the fruit. Most of the waste from the canning industry is now processed into feeds, the most important of which are dried citrus pulp, citrus molasses and citrus meal. These are energy feeds, which must be balanced with roughage and protein feeds. They are high in Ca, and minerals must be supplied to adjust the Ca : P ratio. A mixture of 3 per cent. urea with citrus molasses gives a product with 11 to 12 per cent. crude protein. Rations embodying citrus products for beef cattle are suggested.—T. D. Bell.

3834

CHAPMAN, H. L. (Jr.), KIDDER, R. W. and PLANK, S. W. **Comparative feeding value of citrus molasses, cane molasses, ground snapped corn and dried citrus pulp for fattening steers on pasture.** *Florida Agric. Exp. Stat. Bull.* No. 531, December 1953, pp. 16.

The following rations were compared in a feeding trial with 5 lots of 10 Brahman steers : grazing plus cane molasses free choice ; grazing plus citrus molasses free choice ; grazing plus both types of molasses free choice ; grazing plus 5 lb. ground snapped maize [cereal with attached husk] daily ; grazing plus 5 lb. citrus pulp daily. Average daily gains ranged from 0·55 to 0·82 lb. When this trial, which was made between Oct. and Jan., was repeated between Feb. and June with a second batch of steers on the same grazing the average daily gains were about doubled and this was attributed to the low protein content of the pasture during the first trial. This was proved in a third similar trial from Oct. to Feb. when a supplement of cottonseed meal was given. The results of this trial were comparable with those obtained in trial 2. When the results of the 3 trials were combined there was no significant difference between groups in average daily gain. In the last 2 trials the ground snapped maize was most efficiently utilised. It is concluded that a protein supplement would be beneficial during the autumn and winter months with rations of the types used in these trials.—J. N. Aitken.

3835

O'MARY, C. C. and CULLISON, A. E. **Effects of low level implantation of stilbestrol in steers on pasture.** *J. Animal Sci.*, 1956, **15,** 48–51. [Dept. Animal Husb., Univ. Georgia, Athens.]

Stilboestrol, 24 mg. by subcutaneous implantation, significantly increased the weight gains of yearling and 2-year-old Hereford and Angus steers grazed on mixed grass and legume pasture without supplement. There was no difference in sale price per cwt. No ill effect of treatment was seen.

T. R. Preston.

3836

CLEGG, M. T. and CARROLL, F. D. **Further studies on the anabolic effect of stilbestrol in cattle as indicated by carcass composition.** *J. Animal Sci.*, 1956, **15,** 37–47. [Dept. Animal Husb., Univ. California, Davis.]

In 2 out of 3 feeding trials made in 1955–56, eight 2-year-old Hereford steers had implanted 60 mg. stilboestrol and were fed with 8 control steers for 97 days in trial 1, and 185 days in trial 2. In the third, 2 groups of 14 Hereford yearling heifers, spayed and intact, respectively, were further subdivided into stilboestrol-implanted and untreated animals and fattened for 217 days. The stilboestrol-implanted animals all made greater weight gains, more efficiently, and produced carcases of slightly poorer quality, which contained less separable fat and more lean meat, than untreated animals.

Changes in carcase composition as a result of treatment with stilboestrol were greater in the young heifers than the older steers. There was no effect on blood levels of glucose, N.P.N., Na, K or serum protein-bound iodine, but, in the steers, the weights of the kidneys and of the seminal vesicles increased. Spaying did not affect growth or carcase composition.—T. R. Preston.

3837

O'MARY, C. C., WARREN, E. P., DAVIS, T. J. and PIERCE, H. H. (Jr.) **Effects of low level implantations of stilbestrol in steers fattened on dry lot rations.** *J. Animal Sci.*, 1956, **15,** 52–58. [Dept. Animal Husb., Univ. Georgia, Athens.]

Two experiments are reported. In the first, 24 steers were used as controls, without treatment, and 25 had 36 mg. stilboestrol implanted subcutaneously in the ear for the first period of 42 days. During the next period of 63 days the controls and 15 of the experimental group had no further treatment but 10 of the latter group had a second implant of 36 mg. Over the whole period of 105 days growth rate was significantly increased

by the 36 mg. implant but the second implant at 42 days had no extra effect. The weight of the seminal vesicle was increased in the treated groups, but carcase grade and dressing percentage were unaffected as compared with controls.

In the second experiment, lasting for 140 days, 25 controls had no treatment, 15 had a 36 mg. implant, and 10 had a 12 mg. implant for the first 8 weeks followed by a 24 mg. implant. Over the whole period rate of gain was significantly higher in the group receiving the 36 mg. implant but not in the group having the double implant, although in this group the rate of growth was significantly increased after the second implant.

In both experiments there was a depression of the loin in the treated groups at 85 and 65 days, respectively.—J. S. Thomson.

RAIMONDI, R. Studio dell'influenza esercitata dalla castrazione sullo sviluppo somatico e sui caratteri delle carni di vitelli " Piemontesi " all'ingrasso. 1. 2. [**Effect of castration on somatic growth and carcase character of fattening Piedmontese calves. 1. 2.**] *Ann. Sper. agrar.*, 1955, **9**, 1247–1268 ; 1453–1483. [Ist. Zootec. Piemonte, Turin.] English summary.

1. The Piedmontese breed gives a triple-purpose animal with a distinct bias to beef, and of recent years there has been a tendency to specialise ; the usual products are milk-fed calves about 3 months old, fat calves at 10 to 12 months, young bullocks sold at 18 to 20 months at weights of 400 to 500 kg., and fat animals 5 to 6 years old. Nearly all are castrated by the Burdizzo method at 2 to 3 months of age.

In April 1952, 20 Piedmontese calves of similar type about 20 days old were bought in the market. They were given 20 days to settle down and were inoculated against scours and foot-and-mouth disease. They were then divided into 2 similar groups with mean weights of 72·36 and 72·33 kg. and fed identically, at first on whole milk, concentrates and good meadow hay. At about 3 months of age the calves of one group were castrated. Feeding was based on Scandinavian estimates of requirement and rose from 2·2 feed units daily to 7·02 by the middle of December, *i.e.*, in 250 days. Milk was withdrawn at the end of July. The amount of hay was reduced towards the end of fattening. The concentrate mixtures contained bran, beans, maize, oats and minerals ; the proportion of maize increased in stages, according to the normal practice in the district.

2. After 250 days the entire calves had a mean liveweight of 340 kg., representing an increment of 1·072 kg. daily ; the castrated calves had a mean weight of 316 kg. and a mean daily increment of 0·975 kg. The difference is significant. The mean utilisation of feed, by entire and castrated calves, was 4·087 and 4·490 feed units per kg. liveweight gain and the cost was 10·48 per cent. less for the entire calves.

The bull calves were somewhat more compact and shorter than the castrated calves. Evaluation on the hoof slightly favoured the latter, and their price per kg. liveweight was 380 lire against 365 for entire calves, but the greater weight of the entire calves more than compensated for this.

The carcase weight was 61·62 per cent. of liveweight in entire and 61·53 per cent. in castrated calves. The entire calves gave 8·5 per cent. more carcase. Inspection and chemical composition showed little difference in quality of meat, but the castrated calves gave meat judged to be slightly superior in flavour and tenderness. This would not appreciably affect their commercial value.

It is estimated that if calves to be killed at not more than a year old were left entire, the output from this source in Piedmont alone would be increased by at least 20,000 tons of meat a year.

D. Duncan.

ANTHONY, W. B., STARLING, J. G., MARTIN, C. M., BROGDEN, C. A. and SALMON, W. D. **Fattening rations for finishing steers after summer grazing.** *Alabama Agric. Exp. Stat. Progr. Rep. Ser.* No. 59, November 1955, pp. 8.

In Alabama many beef cattle are sold lacking weight and finish. A series of trials is reported designed to test whether it would be economic to carry such cattle for an extended period on good quality pasture and finish them on homegrown feeds such as snapped maize [cereal with attached husk], groundnut hay, ground cottonseed or cottonseed meal. The results showed that it was more profitable to adopt this procedure and to sell the steers as good to choice than as commercial or utility grades.—J. N. Aitken.

PAWSON, H. C. and INNES, P. **Wintering store cattle : Cockle Park trial, 1954-55.** *Agriculture, J. Minist. Agric. Engl.*, 1956, **62**, 534–539. [King's Coll., Newcastle-upon-Tyne.]

In the eighth successive and concluding trial comparing different systems of winter management

for yearling beef stores, housed bullocks fed on hay, concentrates and roots gained more weight than bullocks wintered outdoors and fed on hay and concentrates. The greater weight gains of bullocks fed on lucerne hay and heifers fed on lucerne silage than of similar animals on seeds hay and grass silage, respectively, were attributed to the higher nutritive value of the lucerne roughages. T. R. Preston.

3842

HUGHES, G. P., ALDER, F. E. and REDFORD, R. A. **The overwintering of beef stores.** *Empire J. Exp. Agric.*, 1955, **23,** 145–157. [Grassland Res. Inst., Hurley.]

Hereford type beef stores, 18 to 24 months old, were fed indoors, outdoors with hand feeding or outdoors on grass during the winters of 1950–51, 1951–52, 1952–53 and 1953–54. In each year indoor cattle made greatest gains in winter, but summer gains were always in favour of those fed outdoors. Combined winter and summer gains varied from year to year, and although generally in favour of the indoor cattle, differences between groups were small and all animals gave satisfactory results at slaughter, irrespective of winter treatment.—T. R. Preston.

3843

GERI, G. La selezione funzionale dei bovini da carne. [**Functional selection of beef cattle.**] *Riv. Zootec.*, 1956, **29,** 11–13.

Selection of lines of cattle suitable for beef production can be based on data relatively easy to obtain, such as birthweight, weaning weight, rapidity of growth and carcase quality ; a crude index of utilisation of feed is helpful.—D. Duncan.

3844

BUTLER, O. D., WARWICK, B. L. and CARTWRIGHT, T. C. **Slaughter and carcass characteristics of shortfed yearling, Hereford, and Brahman × Hereford steers.** *J. Animal Sci.*, 1956, **15,** 93–96. [Texas Agric. Exp. Stat., College Station.]

Slaughter data from 59 Hereford and 90 Brahman × Hereford yearling steers reared uniformly and self-fed in dry lot showed that the crossbreds were 40 lb. heavier at slaughter and had higher dressing percentages and longer legs and carcases. There was little difference between the groups in carcase grade or percentage yield of wholesale cuts.—T. R. Preston.

MILK PRODUCTION

3845

MEHNER, A. and GRABISCH, W. Verzehr, Leistung und Futterverwertung bei der Nutzung von Dauergrünland durch Abweiden und Abmähen. [**Feed intake, production and feed efficiency in the use of permanent pasture by grazing and cutting.**] *Züchtungskunde*, 1956, **28,** 80–88. [Inst. Tierzuchtlehre, Landw. Hochsch., Hohenheim.]

From mid-May to mid-September 1954 about 1 hectare of good permanent grass, divided into 8 plots, was used in rotation by 7 to 9 Jersey cows ; 2 plots were grazed, on the average for 4 hr. daily, for 2 days, then 2 other plots were mown and the grass was given to the cows in stall, and so on, for 4 periods of 2 or 3 weeks ; owing to insufficient growth of grass a fifth rotation could not be completed. In addition to grass the cows had 2 kg. dried beet slices and 120 g. mineral mixture (Ramikal 1) daily throughout. Samples from a plot to be grazed were got by mowing strips at grazing height and used to find the amount of grass available and its composition ; after grazing, the whole plot was mown at the same height and the residue was weighed and analysed. Grass supplied liberally in stall was weighed and sampled and uneaten grass was weighed. Individual milk yields and fat contents were ascertained daily and considered in relation to the grass eaten the day before. The cows were weighed regularly. The results are given in tables.

Over the whole period the average amount of grass eaten per cow daily was the same, 40·1 kg., with both methods of feeding, but the percentage of available grass not eaten was 18·7 for grazing and 6·9 for stall feeding. Average daily milk yield, fat content and milk fat production were 9·1 and 8·9 kg., 5·65 and 5·68 per cent. and 0·514 and 0·505 kg., respectively. On the other hand, because there was less waste with stall feeding, more milk and more fat were got from a given area of pasture by cutting than by grazing, 17·2 and 0·975 kg. per are compared with 16·2 and 0·918 [misprint in paragraph 5 of summary]. The amounts of grass required to produce 1 kg. milk and 1 kg. milk fat were 4·41 and 78 kg. for grazing and 4·51 and 79·5 kg. for stall feeding. The corresponding nutrients were, for grazing, 116 g. digestible protein and 533 starch units, and 2054 g. digestible protein and 9413 starch units ; for stall feeding 129, 605, 2263, 10,641. That is, the grazed pasture was better utilised by the cows, probably owing to selective grazing habits. The results emphasise the importance of careful control of grazing.—W. M. Deans.

3846

WITT, M. Weitere Untersuchungen über die Beeinflussung des Fettgehaltes der Milch durch Beifütterung während des Weideganges. [**Further studies of the effect on fat content of milk of supplements during the grazing season.**] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10,**

375–378. [Max Planck Inst. Tierzucht, Mariensee, Trenthorst.] English summary.

The effects of all-day grazing without supplement on the average yield and fat content of milk of a herd of 66 cows are shown by table and graph. The fat percentage rose rapidly from 3·9 to 4·27 in the first week, then fell equally rapidly and continued to decline to 3·42 in the eighth week, after which there was a slow rise to near the initial value. Milk yield declined gradually. In a short trial with 2 groups of 70 cows, of which one was given a daily supplement of 2 to 3 kg. dried beet slices for 2 weeks in stall and 3 weeks on pasture, the supplement raised the milk yield but had no effect on the fat content. In another trial with 6 pairs of cows, even 12·8 kg. GK-beet was without effect, as were also high-protein supplements. Further investigation of the causes of the fall in the fat content is required.

It is concluded that if pasture is good and plentiful, the giving of supplements is unprofitable. Supplements are appropriate where pasture area is small, or where grass can be preserved for the winter, or where grass tetany is prevalent.

HUTH, F. W. Ergebnisse täglicher Milch- und Futterkontrolle bei Leistungskühen des schwarzbunten Niederungsrindes in Mariensee. [**Daily records of milk production and feed consumption for high-yielding cows of the Holstein Friesian breed in Mariensee.**] *Ztschr. Tiererzücht. Zuchtungsbiol.*, 1955, **66,** 173–202 ; 235–300. [Max Planck Inst. Tierzucht, Mariensee, Trenthorst.]

(a) The cows studied in 1949–50 were in 3 groups ; 11 were in the East Friesian Herdbook, 8 in the Oldenburg Herdbook, and 10 were selected from the herd of the Max Planck Institute on the basis of date of calving. In the following year 3 of the East Friesian group and 7 of the institute herd were studied for a second lactation. Each cow was studied for 365 days after calving. The study began in winter or early spring, and none of the cows calved later than the middle of February ; they were at pasture from the beginning of May until the end of October and indoors the rest of the time.

This first part of the study deals with the milk and fat yields of each cow and the course of lactation.

(b) The cows were fed twice daily, except that the East Friesian and Oldenburg cows had extra concentrates and hay in the evening when in full lactation. Feeds and uneaten feed were weighed to the nearest 100 g. Concentrates were given first, then roots or silage and finally hay. Changes in the ration were made always on Thursdays. The ration was based on maintenance allowances of 300 g. digestible crude protein and 3000 Kellner starch units (S.U.) for a cow of less than 601 kg. liveweight, 330 g. and 3300 S.U. for cows from 601 to 700 kg., and 360 g. and 3600 S.U. for cows of 701 to 800 kg. Production rations were based on 60 g. protein and 275 S.U. per kg. 4 per cent. fat-corrected milk. The rations are shown in tables. While indoors all the cows had 150 g. daily of a mixture of calcium phosphate, calcium carbonate and salts (Viehsalz), and minerals were available to them at pasture.

The intake and yield of each cow during indoor feeding are tabulated, and in another section the intakes of ballast and dry matter. Intakes of ballast and dry matter in individual cows were lowest a few days before calving and rose up to about 8 weeks after calving. Both declined with milk yield, but variations in ballast intake were greater both in the individual cow and between cows than variations in dry matter intake. The mean daily intake of ballast was less than the previously accepted value of 4·3 kg. There was a close relation between milk yield and dry matter intake, $r = + 0{\cdot}828$. A cow which ate 1 kg. more dry matter gave on the average 2·3 kg. more milk, but cause and effect cannot be distinguished. When more concentrates were given less succulent and fibrous feeds were eaten, but the greater the feed capacity of the cow the more concentrates could be taken with a given amount of roughage. Feed capacities of 20 kg. and more dry matter were found in adult cows with high yields of 28 kg. and more. In 26 of 39 lactations studied the feed intake of the cows lay between 18 and 22 kg. dry matter.

Feed utilisation was studied. At the height of lactation, between calving and going out to grass, the 19 East Friesian and Oldenburg cows used 74·2 g. digestible crude protein and 285 S.U. per kg. fat-corrected milk or 1·89 kg. protein and 7250 S.U. per kg. butterfat. The corresponding values for the institute cows were 71·2 g. and 295 S.U., 1·77 kg. and 7310 S.U. As much was needed to produce the last as for the first kg. of milk. Succulent feeds and hay provided about 32·9 per cent. of the total production requirements. The costs were studied and it was found that the most profitable level for each cow was that at which most bulky feeds could be used. Even with the cows which had the greatest capacity the daily yield could not profitably be pushed up above 35 kg. In this way the expenditure on concentrates was not excessive and the health of the cow did not suffer. [This is a selection of only the main points of this long and detailed paper.]

D. Duncan.

CURTO, G. M. Notizie, considerazioni ed esperienze sull'influenza dell'alimentazione sui grassi

del latte nei ruminanti. [**Comments, views and experiments on the effect of diet on milk fat in ruminants.**] *Zootec. Vet.*, 1955, **10,** 437–450; 1956, **11,** 4–16. [Staz. Sper. Zootec., Fac. Agrar., Univ. Milan.] English summary.

The first 7 parts of this paper review and discuss published work on the effects of diet on the percentage of fat in milk (1 and 2), the mechanism of breakdown of carbohydrates in the rumen (3 and 4), the absorption of volatile fatty acids (5), their use (6) and in particular (7) the influence on milk of feeds which produce much acetic acid. The last part describes original work. Six Friesian cows aged from 6 to 8 years were studied about a month after calving. In a preliminary period of 15 days all the cows were fed on hay to cover their maintenance requirements and concentrates according to yield. After this 4 of the cows had pulverised straw added to the concentrates in increasing amounts until after 6 days each cow was receiving 4 kg. straw in addition to the basal ration; the experimental period then lasted 20 days. Two cows served as controls, receiving the basal diet all the time. There was no effect of the increase of crude fibre on the percentage of fat in milk.

The straw was then withdrawn from the ration and for 13 days the intake of hay of the same 4 cows was progressively reduced and that of concentrates increased until the crude fibre intake was for individual cows from 55 to 70 per cent. less than in the basal ration. The hay intake, initially 10 to 13 kg., was reduced to 1 to 3 kg. Milk yield fell, especially in the cow with the highest yield; this cow showed an increase in percentage of fat, the other 3 gave milk of lower fat content than before.

With the same low hay intake, pulverised straw was then again introduced for 6 days; for the next 20 days the fat content of the milk was restored to normal. Lastly, the straw was withdrawn, but the cows received for 20 days 500 g. sodium acetate in water daily. This prevented any fall of milk fat.

It is concluded that coarse forages to supply a modicum of crude fibre are important in maintaining the fat content of milk.—D. Duncan.

3849

HOLMES, W., WAITE, R., MACLUSKY, D. S. and WATSON, J. N. **Winter feeding of dairy cows. 1. The influence of level and source of protein and of the level of energy in the feed on milk yield and composition.**

HOLMES, W. **2. Dried grass produced in spring and in autumn compared with other concentrates and with spring grazing.** *J. Dairy Res.*, 1956, **23,** 1–12; 13–20. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

1. Two experiments were made each with 12 cows forming four 3 × 3 Latin squares. Each cow spent 4 weeks on each ration, but milk yields during the last 3 weeks only were used to assess the results. The basal rations were of dried grass, hay and roots in amounts sufficient for maintenance and the first 5 lb. milk in the first experiment and for maintenance and the first 7·5 lb. milk in the second. The level of rationing was about 10 to 15 per cent. above the Woodman standards.

In the first experiment 3 concentrate rations were compared. The digestible crude protein (D.C.P.) contents were 10, 15 and 17 per cent.; the starch equivalent (S.E.) content was held constant at 63·5 per cent. Statistical analysis of the results showed no difference in milk yield, milk composition or liveweight gain except that the concentrate containing 17 per cent. D.C.P. gave milk with a slightly lower fat content.

The second experiment was similar except that D.C.P. content of the 3 concentrate mixtures was held constant at 16 per cent. and the S.E. was adjusted to 59, 67 and 75 per cent. The mixtures containing the higher levels of S.E. gave significantly more milk and tended to increase liveweight. The solids-not-fat content of the milk increased when the S.E. level was raised from 59 to 67 per cent. but there was no further increase at the 75 per cent. level. The fat content of the milk was reduced at the 75 per cent. S.E. level. The ration containing only 10 per cent. D.C.P. was the most economical. It was concluded that a level of feeding from 110 to 117 per cent. of the Woodman standards would be the most economical for winter milk production.

2. Experiments similar in design to those reported above were made to compare dried autumn and spring grass as concentrates with one another and with a mixture of oats, beans and dried grass. In a second experiment dried autumn grass plus oats and dried spring grass plus oats were compared with one another and with a concentrate mixture made up mainly of imported feeds. The basal rations consisted of hay, swedes and oat straw. In the first experiment equal amounts of oats and dried grass were given as part of the maintenance ration.

In both experiments animals fed on dried spring grass gave slightly more milk than those on dried autumn grass. The yield of milk from cows given the mixture of oats, beans and dried grass was about equal to that of cows given the dried spring grass. The highest milk yields were obtained when the mixture of imported feeds was given. Cows on dried spring grass during the last period of indoor feeding showed the least increase in milk on going to grazing, and those on the mixture of oats, beans and dried grass showed the highest increase. The high yields obtained with the

imported feed mixture were thought to be due to the greater amount of nutrients supplied by this ration. It was concluded that the spring grazing stimulated yields for the same reason.

J. N. Aitken.

3850

LARSEN, L. H. and LARSEN, H. Fodringsintensitetens og fodersammensætningens indflydelse på malkekøernes rentabilitet, holdbarhed og drægtighedsforhold, 1935–1954, Favrholm. [**Effect of plane of nutrition and composition of the diet on the economic return from dairy cows, productive life and reproduction: 1935 to 1954, Favrholm.**] *Forsøgslab. København Beretn.*, 1956, No. 285, pp. 168. English, French, German and Italian summaries.

In this 19-year-long experiment, plane of nutrition was adjusted as follows: normal, 0·4 production feed unit (F.U.) and 60 g. digestible true protein per kg. 4 per cent. milk; low-plane, 0·33 F.U. and 50 g. protein; high-plane, 0·476 F.U. and 71 g. protein. Within the normal and high groups the proportion of succulent fodder was varied so that part had 4 F.U. roots and the remainder 5 F.U. roots and 2 F.U. silage. The low-plane groups had 4 F.U. roots and all had 1 F.U. each of hay and straw. A sixth high-plane group had 5 F.U. roots without silage. This plan was maintained for 10 years; thereafter all groups had in summer a supplement of silage if required and if silage was to be had. The concentrate mixtures used changed in detail over the 19 years but were always of the same type and the same for all groups in any one year. An example from 1942–43, when it was difficult to maintain the standards, is given as follows: winter mixture C: 50 parts sunflower cake, 43 mustard seed meal, 5 sesame cake, 2 cottonseed cake; winter mixture A: 20 parts C mixture, 10 coconut cake, 10 urea cake [not described], 30 oats and 30 barley. Summer mixture: 40 parts rye bran, 20 oats, 20 barley, 10 urea cake, 5 coconut cake and 5 mustard seed meal. In the above order these mixtures provided, per 100 kg., 105·1 F.U. and 311 g. digestible true protein, 90·2 F.U. and 119 g. protein and 81 F.U. and 90 g. protein. They were given according to yield of 4 per cent. milk, and, in summer, yield and quality of pasture.

The experiment began with 6 herds, each of 6 Red Danish cows, comparable in age, breeding, size, condition and time of calving. These were to be brought up to 12 either with their own calves or calves from the parent Favrholm herd. There was no interchange between experimental herds and when they reached the planned number, each was maintained by replacements within itself. At any one time, the same bull was used in all herds.

Average annual yield in kg. and fat per cent. for the 19 years were: normal plane, 4239 and 4·13; normal plane with high roots and silage, 4199 and 4·24; low-plane 3796 and 4·12; high-plane 4279 and 4·07, with high roots and silage 4198 and 4·16, with high roots without silage 4505 and 4·12. The high-plane increase of roughly 20 per cent. in both F.U. and g. protein gave only an insignificant increase in yield; the reduction of 20 per cent. reduced yield by 10 per cent.

The economics of production are analysed in detail with special reference to the use of succulents. Normal plane, high succulents gave the best returns and high plane, high succulents the second best.

There were in all 1802 services for 798 pregnancies. In the order normal plane with 2 groups, low plane, high plane with 3 groups, services per conception were 1·91, 1·72, 1·74, 1·98, 1·81, 1·92, and per cent. pregnant to first service 54·7, 61·9, 59·9, 49·2, 58·5 and 49·6. A more stringent analysis with exclusion of all disturbing abnormalities showed that in the high-plane herd, milk yield had no effect on breeding performance; in the normal and low-plane herds performance deteriorated as yield rose.

Taking the herds in the same order, the average herd life in years and number of cows, in brackets, were: 5·75 (31), 5·73 (32), 5·98 (30), 5·05 (35), 4·52 (37) and 5·72 (31). Causes of removal from the herd are tabulated for each herd in 2 lists, those that could not be associated with the plan of feeding and those that might be affected by composition of the diet or plane of nutrition. When the experiment terminated, no addition had been made for 4 years on account of a programme to eradicate abortion (see p. 8 of the report), and only 11 cows remained. Including these, there were 92 in the list of causes independent of diet and 104 in the list of causes possibly dependent on diet. Of these the chief with 69 disposals was sterility, the next with 11 old age.

There was no effect of plane of nutrition on weight of calves.

Details of these and other findings and of feed consumption are set out in 12 "main" tables. There are 24 summary tables and 37 graphs in the text.—I. Leitch.

3851

NORDFELDT, S., HELLEDAY, T. and MÅNSSON, N. C. (with HJELM, L. and SWARTLING, P.) Undersökningar över avkastningsresultaten för kor av låglandsras jämförda med resultaten för kor av jerseyras. [**Returns from Holstein-Friesian compared with Jersey cows.**] *Kgl. Lantbrukshögsk. Statens Husdjursförsök Särtryck* No. 113, 1955, pp. 15. English summary.

The tests continued over 2 years, in the first with 7 Holstein and 10 Jersey, and in the second with 9 Holstein and 11 Jersey cows. Details are

given of feed consumption, yield and composition of milk, liveweight and cost and value of produce and some data for the feeding of the calves to 180 days of age. A special study was made to compare profits assuming a productive life of 5 years and 4·5 calves, and costing at 1953–54 prices. The Holstein cows earned more in milk, ratio roughly 5 : 4 ; calves, ratio 2 : 1 ; cows disposed of, ratio 10 : 6·5 (total ratio 11·6 : 8·6), and cost more in feed and labour, ratio 4·6 : 3·5, so that the surplus per cow in Kr. was 7005 for Holsteins and 5374 for Jerseys or less if the overprice for fat was less. The last section of the report gives average composition of Holstein and Jersey milk during stall feeding and grazing in 1953 and 1954.—I. Leitch.

HANSEN, K. Afkomsprøver med tyre. [**Progeny-testing of bulls.**] *Forsøgslab. København Beretn.*, 1956, No. 286, pp. 235. English and German summaries.

The test year began on 1 September. Before calving the heifers were given, in addition to grazing, 4 feed units (F.U.) roots with 172 g. digestible true protein, 1 F.U. beet tops with 120 g. protein and 2 kg. concentrates (30 cake and 70 barley) with 272 g. protein. After calving, winter feed for yields of 10·5 kg. or more was, in kg., 1·5 swedes, 3·25 beets, 1 beet-top silage, 2·5 hay, 2·0 concentrate mixture 1 and amounts of concentrate mixture 2 increasing by 0·4 kg. per kg. 4 per cent. milk above 11·5 kg. Mixture 1 was of soya bean meal 15, cottonseed cake 27, sunflower expeller meal 25, expeller rape seed meal 8, coconut cake 18, molasses 5 and dicalcium phosphate 2 per cent. Mixture 2 was of mixture 1, 35, wheat bran 15, barley 48 and dicalcium phosphate 2 per cent. On the average 0·41 production F.U. and 65 g. digestible true protein were taken per kg. 4 per cent. milk. In the grazing season a concentrate mixture of mixed grains 60, oilcake 30 and molassed bran 10 per cent. was given according to milk yield and assessed quality of pasture.

For 5167 Red Danish heifers tested between 1945 and 1955 the average milk yield was 4344 kg. with 4·42 per cent. fat ; for 675 Holsteins 4228 and 4·29 ; for 394 Jerseys 3158 and 6·18 ; and for 65 Shorthorns 3460 and 4·09. The average total feed cost in stall of 4 per cent. milk was 1·42 Kr. per F.U.—I. Leitch.

BECKER, R. B., ARNOLD, P. T. D. and SPURLOCK, A. H. **Productive life-span of dairy cattle.** *Florida Agric. Exp. Stat. Bull.* No. 540, March 1954, pp. 18.

A survey of 101 Florida dairy herds showed that the productive life of dairy cows in herds maintained by purchased replacements was 3·9 years compared with 4·7 years in 14 herds in which replacements were reared at home. The main reasons for disposal were udder troubles, low milk production and infertility. An analysis of the reasons for early disposal of 2254 bulls in natural service showed that 34·5 per cent. were discarded to avoid inbreeding, 14·1 per cent. for bad disposition and 10·4 per cent. for low production of daughters.

Study of the reasons for discontinuing the use of 5177 bulls in natural service showed that 28·9 per cent. were disposed of owing to sterility. Bulls used in artificial insemination stations had an average useful period of 2·72 years.—J. N. Aitken.

AURIOL, P. Influence du mois de vêlage sur la production laitière des vaches Pie rouge de l'Est, dans le Jura. 1. Premières observations. [**Effect of month of calving on milk production of Eastern Red Pied cows in the Jura. 1. Preliminary observations.**] *Ann. Zootech.*, 1955, **4**, 189–200. [Stat. Recherches Élevage, C.N.R.Z., Jouy-en-Josas.]

The region studied was selected for homogeneity of climate, insolation and mode of husbandry, and was limited to the plateau of Nozeroy. The herds were in about 20 communes situated between 750 and 850 metres above sea level and in an area with a heavy rainfall and much snow. The cattle were housed from 15 October to about the first half of May. Natural pasture, about 40 per cent. of the total area, provided most of the cattle feed as grass in summer and hay in winter ; silage was forbidden because the milk went for Gruyère cheese. All the cattle were of the Eastern Red Pied breed and most of them of the Montbéliard strain. Milk records were taken from monthly weighings, and production was expressed on the basis of the lactation and not of the year. Abnormal lactations, after abortion or with mastitis, and those in which the interval between calving and next pregnancy was more than 5 months,

were eliminated. The cows were all milked twice daily.

The 240 selected records were for cows in 20 herds in 1953 and 1954. The mean yield was a little above the average for the whole district. Feeding practice varied considerably. Few cows calved in July and August, but mean yields for the cows calving in the months from October to June are tabulated. The highest yields were from cows calving in October, November and December, and cows calving in December gave 24·8 per cent. more milk than those calving in June. The coefficient of persistence of lactation (Delage *et al.*, *Ann. Zootech.*, 1953, **2**, 225) was highest in autumn calvers and lowest in those which calved between March and May. The duration of lactation was greatest after October calving and least after May calving. There was little effect of month of calving on the maximum daily yield, and the variation with month was only about 10 per cent. It is proposed to examine next the influence of the age of the cow.—D. Duncan.

SIRRY, I. and HASSAN, H. A. **The effect of potassium-iodide feeding on milk production and composition, and on general condition, in the Egyptian buffalo.** *Empire J. Exp. Agric.*, 1955, **23**, 214–219. [Fac. Agric., Univ. Cairo.]

Potassium iodide, 120 mg. daily, in mid-lactation significantly increased milk and butterfat yield of buffaloes over that of similar untreated animals. Percentage solids-not-fat, sp. gr. and acidity of the milk increased, but butterfat percentage decreased. There was some indication of a greater persistency of lactation in treated animals. Body temperature and pulse rate were not affected.—T. R. Preston.

3858

NELSON, A. B., MACVICAR, R. W., CAMPBELL, W. D. and ROSS, O. B. **Supplements of different protein and vitamin-mineral content for wintering bred yearling heifers.** *Oklahoma Agric. Exp. Stat. Bull.* No. B-460, September 1955, pp. 11.

In-calf Hereford heifers outwintered on grass and given 2·5 lb. daily of a 40 per cent. protein supplement gained on the average 56 lb. per head more than similar heifers given 2 lb. of a 20 per cent. protein supplement. The difference between the groups disappeared by the end of the summer grazing season. The addition of vitamins and minerals to the supplements had little effect. The birthweights and weaning weights of the calves were not significantly different.—J. N. Aitken.

3859

BRANDSMA, S. De mineralen in de voeding van het rundvee. [**Minerals in the feeding of cattle.**] *Verslag* 1954 *Vereniging Exploitatie Proefzuivelboerderij Hoorn*, 1–12. [Rijkslandbouwproefstat., Hoorn.]

The K requirement of a milk cow of 500 kg. liveweight giving 20 kg. milk has been estimated as 55 g. daily; her intake from pasture may be as much as 10 times that. Caution is therefore required in respect of the persistent use of K fertilisers and farm manure, especially in areas where Na or Mg or both are below normal. The daily Na requirement of the same cow is assessed at 22 to 24 g. Pasture may, or may not, supply that amount. Hence the need to provide salt licks and to replace pure K fertilisers by compounds that contain Na. Requirement for Cl is at least 42 g. Most pastures and indoor rations provide plenty. Modern estimates of Ca requirement, still for the same cow, are from 56 to 84 g. Some grass pastures may provide less than this; some rich in clover or lucerne may provide too much and require supplements of P, of which the basic requirement is about 46 g. The Mg requirement of about 30 mg. is often not supplied by pasture alone. The replacement of pure K fertilisers by compounds that contain Mg should help.—I. Leitch.

3860

MCDANIEL, A. H. and ROARK, C. B. **Performance and grazing habits of Hereford and Aberdeen-Angus cows and calves on improved pastures as related to types of shade.** *J. Animal Sci.*, 1956, **15**, 59–63. [Louisiana Agric. Exp. Stat., Baton Rouge.]

In experiments made over 4 years with Hereford and Aberdeen-Angus cows and calves rate of liveweight gain, time spent grazing and time spent lying down were directly, and time spent standing indirectly, related to the amount of shade available to the animals. Calves were less affected by the different amounts of shade than were the cows.

ROLLINSON, D. H. L., HARKER, K. W., TAYLOR, J. I. and LEECH, F. B. **Studies on the habits of Zebu cattle. 4. Errors associated with recording technique.** *J. Agric. Sci.*, 1956, **47**, 1–5. [Animal Health Res. Centre, Entebbe, Uganda.]

For previous parts see Absts. 5400, Vol. 24; 4335, 5822, Vol. 25.

Five observers recorded simultaneously the grazing habits of 10 cattle during 1½- or 2-hr. periods. The standard errors of observations made at 1-min. or 4-min. intervals were 3·20 and 7·36 per cent. of the general mean, respectively. It is concluded that recording at 4-min. intervals was sufficiently accurate for the "major" activities and that differences between observers were unlikely to be important in practice.

J. L. Corbett.

WALSER, K. Laktation und Abortus. Ein Beitrag zur Kenntnis der Laktationsverhältnisse nach Fehl- und Frühgeburten der Rinder. [**Lactation and abortion. Effect on lactation of abortion and premature birth in cows.**] *Ztschr. Tierzücht. Züchtungsbiol.*, 1955, **66**, 38–64. [Inst. Geburtshilfe, Tierärztl. Fak., Univ. Munich.]

The cows were all in herds whose yields were recorded by South Bavarian recording associations. The cause of abortion was usually brucellosis or trichomoniasis. The milk yields were studied in 310 cows which aborted before the completion of a previous lactation, 97 cows which were dry before they aborted and 84 heifers which aborted a first calf.

The cows of the first group gave on the average only 2280 kg. milk after aborting, against 3360 kg. in their recorded normal lactations. The variability was large. The loss was due mainly to a smaller output in the early part of the lactation; the decline was slower than normal. The difference in loss between cows which aborted before and after the end of the fifth month of pregnancy was not significant. The age of the cow had no significant effect. The normal milk yield had a significant effect; the percentage loss increased with normal yield and the means were 28·5 and 35·1 for cows giving normally less and more, respectively, than 3300 kg. Yields after autumn abortions were 15 to 20 per cent. less than those after spring abortions.

Cows which were dry before they aborted gave 20 ± 17 per cent. less than their normal milk yields; losses were slightly, but not significantly, less when the dry period was long.

Heifers which aborted their first calf gave on the average 20 per cent. less milk than the average for normal heifers in the same books. There was no effect on the subsequent lactation.

D. Duncan.

MAYMONE, B. and REGENSBURGER, G. Contributo allo studio dell'azione esercitata dalla capraggine (*Galega officinalis*, L.) sulla produzione del latte nei bovini. [**Effect of goat's rue (*Galega officinalis*, L.) on milk yield of cows.**] *Ann. Sper. agrar.*, 1956, **10**, 7–24. [Ist. Sper. Zootec., Rome.] English summary.

Hay made from goat's rue is not accepted by cows, so the ground seeds were used, on the assumption that the effects ascribed to the plant are due to the alkaloid galegin, which is in highest concentration in the seeds. In a preliminary test it was found that 300 g. daily could be eaten by cattle without sign of poisoning.

Ten Friesian cows were divided into 2 groups of 5 as nearly as possible paired for age, stage of lactation, bodyweight and milk yield. After 10 days of preparation the cows of group 1 received 300 g. daily of goat's rue seeds mixed with their concentrates. This continued for 20 days, then for 10 days neither group received goat's rue, and finally group 2 received 300 g. per head daily for 20 days. The cows had a mixed basal diet of lucerne hay, dried beet pulp and a concentrate mixture.

While they were being given goat's rue the cows ate an extra 0·3 feed unit daily from the goat's rue and 0·25 feed unit of other feeds, providing together 95 g. digestible protein. There was no significant effect on bodyweight or on yield or composition of milk. It was estimated that the dose of galegin was 6·6 mg. per kg. liveweight daily.—D. Duncan.

DAHM, P. A. and JACOBSON, N. L. **Effects of feeding Systox-treated alfalfa hay to dairy cows.** *J. Agric. Food Chem.*, 1956, **4**, 150–155. [Iowa State Coll., Ames.]

Systox is a proprietary insecticide containing an emulsifing agent and an organic thiophosphate, demeton. A 2·58 acre field of alfalfa was sprayed at the rate of 6·2 oz. per acre. The crop was mown 27 hr. and baled 75 hr. after treatment. The hay was used in 2 feeding trials with milking cows. The toxic effects of demeton were demonstrated in a preliminary trial with one cow, which received it in capsule in increasing amounts for 3 consecutive days as follows: first day 0·1, second day 0·51 and third 2·5 mg. per kg. bodyweight. By the end of the third day the cow showed signs of intoxication, had diarrhoea and went off feed. Milk samples taken 1 and 6 hr. after the third feeding contained substances which inhibited the cholinesterase present in plasma used for analysis. When the same cow was given increasing quantities of treated hay for 49 days no significant inhibition of cholinesterase by milk occurred. A similar result was obtained when the treated hay was given to 3 cows for 56 days. The cholinesterase activity in the red blood cells declined as the feeding of the hay was prolonged. That of 2 cows which received a normal ration remained constant

throughout the experiment. It was concluded that the detoxication did not involve the process of milk secretion.—J. N. Aitken.

ROGNONI, G. Alcuni aspetti dei rapporti tra alimentazione e fertilità delle bovine da latte. Indagine sull'influenza del residuo acido basico e del rapporto Ca/P dei foraggi. [**Diet and fertility in milk cows. Effect of acid base balance and Ca : P ratio of fodder.**] *Zootec. Vet.*, 1956, **11,** 55–64. [Ist. Genetica Animale, Fac. Agrar., Univ. Cattol. Sacro Cuore.] English summary.

The study was made on a dairy herd of about 2000 cattle of several breeds, including about 1000 cows and pregnant heifers distributed in about 30 farms. Some of the cattle were imported.

The fertility of the cows between 1951 and 1954 varied from 89·63 to 78·70 per cent. For all cows the mean number of services per pregnancy ranged from 2·32 to 2·69, but for all cows got in calf within 4 months of parturition and with not more than 4 services it was 1·94. The percentages of pregnancies following only 1 service were from 37·1 to 40·9 for all cows and from 43·9 to 47·7 for the selected group. Results were worst in summer, when the cows were receiving concentrates only for milk beyond the first 14 litres. The feedingstuffs were analysed. [The results are said to be in Table 5, but this table appears to be missing.] It was concluded that the acid base balance of the fodder was too alkali-forming, that the Ca : P ratio was too high and the Mg : Ca and Na : K ratios too low and that there was a deficiency of Cl. It was therefore decided to try the effect of a mineral supplement in some groups of cows with particularly poor fertility, 243 cows in all. These cows received a mineral mixture designed to reduce the Ca : P ratio, correct the deficiency of Cl and improve the K : Na ratio. This was begun in 1953, and by 1954 there was a striking improvement in breeding results. Compared with 1951–52, the number of services per pregnancy in this group had fallen from 3·22 to 1·88 and the percentage of successful first services had risen from 24·1 to 49·7. The winter results were no longer better than those in summer.—D. Duncan.

MUNRO, J. **Observations on the suckling behaviour of young lambs.** *Brit. J. Animal Behaviour*, 1956, **4,** 34–36. [Dept. Agric., Univ. Aberdeen.]

The suckling behaviour, under natural conditions, of 2 sets of Blackface twin lambs was recorded for continuous 16-hr. periods during daylight once a week for the first 6 weeks of life. Similar observations were made of 2 single Blackface lambs for 6-hr. periods in daylight each week. Twin lambs over this period were suckled 22 times in 16 hr. and single lambs 14 times in 6 hr. Lambs were suckled less frequently and for shorter periods as they grew older.—J. C. Gill.

3868

JÓNSSON, G. Tilraunir með síldarmjölsgjöf handa beitarám um meðgögutímann 1950–1954. [**Feeding trials with herringmeal for pregnant ewes, 1950-1954.**] *Rit Landbúnaðardeildar, A-Flokkur*, 1955, No. 10, pp. 30. [Reykjavik.] English summary.

Ewes on pasture receiving 100 g. herringmeal daily did not thrive better than ewes receiving 50 g. herringmeal daily during the first 3 months of pregnancy when over 30 per cent. of maintenance requirements was met by good quality hay ; 50 g. herringmeal daily also proved sufficient during the last 2 months of pregnancy provided 50 to 60 per cent. of maintenance requirements was met by hay. When less hay was given the ewes receiving 50 g. herringmeal were in poorer condition than those receiving 100 g., which pointed to deficiency of protein or minerals or both in the pasture. In 3 of the 5 trials significantly heavier twins were produced by the ewes receiving 100 g. herringmeal. From the results the appropriate levels of herringmeal feeding for different conditions are given. (From summary.)—J. C. Gill.

BURKITT, W. H., LEWIS, J. K., VAN HORN, J. L. and WILLSON, F. S. **Wood molasses compared with cane molasses for lambs and steers.** *Montana Agric. Exp. Stat. Bull.* No. 498, June 1954, pp. 18.

Over 4 years of tests, wood molasses was found to be a satisfactory part replacement, up to 20 per cent., for barley and oats in lamb rations,

causing no harmful effect and proving very palatable. Its feeding value was equal to that of cane molasses when given on an equal dry matter basis. Apparent digestibilities of individual nutrients and of total digestible nutrients of the total ration were similar whether the concentrate portion contained no molasses, cane molasses or wood molasses. The taste of the mutton was unaffected. Wood molasses was comparable with cane molasses for feeding steers, and a satisfactory pellet could be produced when it was included in the ration at a 10 per cent. level.—J. C. Gill.

3870

TILLMAN, A. D. and MACVICAR, R. **The effect of chlortetracycline upon digestion of ration components, retention of nitrogen and volume of urine excreted by sheep with observations on rectal temperatures.** *J. Animal Sci.*, 1956, **15,** 211–217. [Oklahoma Agric. Exp. Stat., Stillwater.]

In trials with over 50 sheep digestibility of the ration and N retention were not affected when chlortetracycline was given at the rate of 11·8 mg. per 100 lb. bodyweight. Digestibility of dry matter, crude protein, crude fibre, N-free extract and energy were reduced but N retention was unaffected when chlortetracycline was given at a level of 15·4 mg. per 100 lb. bodyweight. The antibiotic significantly depressed rectal temperature and slightly increased excretion of urine.

J. C. Gill.

3871

JORDAN, P. S., JORDAN, R. M. and CROOM, H. G. **Effect of chlortetracycline, stilbestrol and chlortetracycline-stilbestrol supplements on fattening lambs.** *J. Animal Sci.*, 1956, **15,** 188–192. [Minnesota Agric. Exp. Stat., St. Paul.]

Rate of gain, feed consumption and efficiency of use of feed of lambs on concentrate and roughage (35 : 65 and 45 : 55) were not affected by the addition of 21·6 mg. chlortetracycline or 2 mg. stilboestrol or both. Carcase yield was not affected by treatment or by the concentrate to roughage ratio, but carcase grade was improved by higher concentrate feeding and by the addition of chlortetracycline.—J. C. Gill.

3872

JOHNSTON, E. F., HUDSON, F., BOGART, R., OLIVER, A. W. and MCKENZIE, F. F. **The effects of injected testosterone on adult ewes.** *J. Animal Sci.*, 1956, **15,** 177–184. [Dept. Animal Husb., Oregon Agric. Exp. Stat., Corvallis.]

In a trial with 8 adult ewes 100 mg. testosterone injected weekly produced male behaviour, enlarged clitorides, smaller hearts and smaller thyroid glands but did not affect weight gain or carcase grade. Weights of liver, kidney, adrenal, pituitary and ovary were not affected. Four days after treatment ceased no active residual testosterone was found in the meat. Seventeen days after treatment the clitorides of treated ewes had partly regressed from the enlarged state.

J. C. Gill.

3873

JOHNSTON, E. F., HUDSON, F., BOGART, R. and KAUFMES, J. **Retention of injected testosterone in the meat of adult ewes.** *J. Animal Sci.*, 1956, **15,** 185–187. [Dept. Animal Husb., Oregon Agric. Exp. Stat., Corvallis.]

The bodyweight and comb length of cockerels fed on meat from 4 ewes treated with testosterone did not differ from those of cockerels fed on meat from 4 untreated ewes, but comb height of cockerels fed on meat from the untreated ewes was significantly greater. The results indicated that there was no residual testosterone in the meat of ewes 4 days after treatment ceased.—J. C. Gill.

3874

WHITING, F. and CLARK, R. D. **The concentrate to roughage ratio in the ration as it affects the performance testing of rams.** *Canad. J. Agric. Sci.*, 1955, **35,** 518–524. [Div. Animal Husb., Exp. Farms Serv., Canada Dept. Agric., Lethbridge, Alta.]

Nineteen sire groups of 4 ram lambs each representing Rambouillet, Canadian Corriedale and Romnelet breeds were used in a 2-year trial to evaluate rations for testing performance of rams. The concentrate : roughage ratios studied were 2 : 1, 1 : 1, 1 : 2 and free choice (about 5 : 1). Data were analysed for different bodyweight ranges and time intervals. Groups differed significantly in average daily gain and efficiency of use of feed, but there was no difference in variability within those groups with concentrate to roughage ratios of 2 : 1, 1 : 1 and 1 : 2. On free choice, daily gains were more variable, but not feed efficiency. Sire group differences in daily gains were significant only from 90 to 130 lb. bodyweight and in feed efficiency during the first 112 days on feed. Correlations between daily gains and feed efficiency were lower on free choice. Average correlation between initial weight and gain was not significant, but that between initial weight and feed efficiency was significant.

J. C. Gill.

3875

BOGART, R. and HEDRICK, D. W. **Managing sheep on hill pastures.** *Oregon Agric. Exp. Stat. Bull.* No. 554, November 1955, pp. 15.

Studies, over 8 years, on the better use of hill pasture for producing fat lambs off grass indicated that sheep should be grazed on both improved and unimproved pastures at the pastures' maximum productivity and that the green feeding period

should be extended by making silage from excess grass in the spring, by the use of fertilisers and by good management. Grasses and legumes should not be too heavily grazed and should be of highest quality for ewes and lambs. After weaning the ewes should be put on less luxuriant pasture. Breeding pasture should be plentiful and nutritious. Highly productive pasture should be grazed by the heavier breeds, *e.g.*, Hampshires and Suffolks, and poorer pastures by Cheviots. Long-wooled breeds can stand up to wet weather and their lambs are improved when Southdown tups are used instead of Suffolks. Pasture with $\frac{1}{2}$ lb. grain per head daily is sufficient for winter feeding in open weather, and $\frac{3}{4}$ lb. grain plus hay and silage during snow. To combat parasites and infective disease in general, rotation of grazing is recommended and a one-year plan is shown for running 200 ewes on 4 pastures.—J. C. Gill.

3876

ANGEL, H., CHARLET, P. and POLY, J. Quelques résultats sur les aptitudes zootechniques des brebis de race Lacaune. [**Productive capacity of Lacaune sheep.**] *Ann. Zootech.*, 1955, **4,** 233–239. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

In 1947 and 1948 a study was made of 73 Lacaune ewes in 6 small flocks at Montlaur in the Camarès. The flocks contained from 7 to 18 ewes; mean duration of lactation was from 158 to 180 days, milk yield from 110·34 $\pm$ 4·39 to 150·01 $\pm$ 5·59 kg., fleece weight from 1·18 $\pm$ 0·14 to 1·92 $\pm$ 0·19 kg. and chest girth 0·934 to 0·972 m. The last 3 characteristics were subjected to analysis of variance.

Chest girth did not differ more between flocks than between individuals in flocks, but the differences between flocks in milk yield and fleece weight were significant. The correlation between milk yield and fleece weight was not significant. The proportion of the body surface covered with wool bore no relation to the milk yield, but its positive correlation with fleece weight was highly significant. It was found that 51·4 per cent. of the variation in fleece weight could be explained by this variation in " covering index ".

Work is to continue with the same sheep.

TANEJA, G. C. **Mutton qualities in Australian Merino sheep.** *Austral. J. Agric. Res.*, 1955, **6,** 882–890. [Sch. Wool. Technol., New South Wales Univ. Technol., Sydney.]

A study of bodyweight and body dimensions of 557 Peppin Merino ewe lambs and the relationship of these measurements to mutton quality is reported, with measurements of body length, depth and width, fore cannon length, mutton score, fold score and bodyweight at 5, 11 and 17 months. Repeatability ranged from 0·46 for body length to 0·77 for body depth. Fold score was negatively correlated with mutton score, and no significant correlation was found between mutton score and cannon length; apart from these, all pairs of characters studied showed a significant positive correlation. The best measure of mutton quality was bodyweight at 11 months.—J. C. Gill.

3879

DRAGICEVIC, M. C. Contribucion al estudio de metodos de determinacion de rendimiento en lanas de ovinos. [**Methods of estimating yield of wool by sheep.**] *Bol. Inst. Nac. Invest. agron. Madrid*, 1955, **15,** 455–529. [Fac. Agronom., Univ. Chile.] English summary.

The " core test " for estimating the yield of clean wool from the unwashed fleece is described. It consists in taking a sample of wool from the centre of a number of bales of the lot of wool, weighing, washing and removing impurities. The number of samples taken depends on the size of the lot. Samples for testing are sent from the shearing sheds or warehouses and a report can be supplied within 48 hr. of arrival of the sample at the laboratory.

The method was used on 69 samples of wool from 8 farms. Yields of clean wool were from 50 to 63 per cent. of the unwashed fleece, values in which allowance is made for atmospheric humidity. Significant inverse correlations were found between fineness of wool and yield. There was no significant correlation between the estimated yields of whole fleeces, pieces or shearings from the belly, or between 3 groups of farms on which rearing and conditions were different. The difference between the yield estimated visually and that found by the

core test was statistically significant in most cases, and when this was not so it was probably because of the small number of samples available for analysis.
T. D. Bell.

3880

SCHINCKEL, P. G. **Body-weight—fleece-weight relationships in a strain of Merino sheep.** *Austral. J. Agric. Res.*, 1956, **7**, 57–75. [Agric. Coll., Roseworthy, South Australia.]

No correlation was found, except in one out of 10 groups, between bodyweight and wool production per unit area of body surface in a flock of Merino sheep examined at intervals over 7 years. A highly significant correlation was found between clean fleece weight and clean wool per unit area of body surface in the midside region. It is concluded that wool production is proportional to fleece-bearing surface, since the regression of log fleece weight on log bodyweight never differed significantly from 0·60 and 0·60 is the regression of log surface area on log bodyweight in sheep. No significant difference was found between sires in the regression of log fleece weight on log bodyweight, but highly significant differences were found between sire groups in mean log fleece weight after allowing for differences in log bodyweight. Left midside areas of lambs measured every 4 months from 4 to 28 months produced wool in amounts proportional to the area in each of the 6 periods. Differences in the amounts produced were highly significant both between periods and between sheep.—J. C. Gill.

SIDWELL, G. M., JESSUP, G. L. (Jr.) and MCFADDEN, W. D. **Estimation of clean fleece weight from small side samples and from wool density, body weight, staple length and grease fleece weight.** *J. Animal Sci.*, 1956, **15**, 218–224. [Southwestern Range and Sheep Breeding Lab., Fort Wingate, N. Mex.]

The method of Neale and McFadden (*New Mexico Agric. Exp. Stat. Press Bull.* No. 1131, 1954) of estimating clean fleece weight from density, staple length, bodyweight and grease fleece weight was found to be more accurate and cheaper than that of scouring small samples. Calculations on the results from the 344 sheep studied showed that little information was lost when density and bodyweight were omitted. Multiple regression coefficients of clean fleece weight in lb. on staple length in inches and grease fleece weight in lb. were 0·61 ± 0·04 and 0·36 ± 0·01, respectively.

SHORT, B. F. **Developmental modification of fleece structure by adverse maternal nutrition.** *Austral. J. Agric. Res.*, 1955, **6**, 863–872. [Div. Animal Health Prod., C.S.I.R.O., Sheep Biol. Lab., Prospect, N.S.W.]

Bodyweight and the ratio of secondary to primary (S/P) fibres of lambs at birth were reduced but S/P follicle ratio was unaffected by severe restriction of feed intake of ewes throughout pregnancy. Lambs from these ewes made poor growth despite good feeding of the ewes during lactation, and restricted final S/P ratios and number of fibres per unit area of skin resulted. At 7 months of age there was no difference in bodyweight or clean wool production per head or per unit area of the lambs from ewes well fed and from those poorly fed during pregnancy. Longer and coarser wool fibres were grown by lambs with fewer mature follicles per unit area than by those with higher fibre densities.—J. C. Gill.

3883

DALY, R. A. and CARTER, H. B. **Fleece growth of young Lincoln, Corriedale, Polwarth and fine Merino maiden ewes grazed on an unimproved paspalum pasture.** *Austral. J. Agric. Res.*, 1956, **7**, 76–83. [Wool Biol. Lab., Div. Animal Health and Prod., C.S.I.R.O., Sydney, N.S.W.]

Liveweight and wool production of 2 Lincoln, 2 Corriedale, 2 Polwarth and 2 fine Merino maiden ewes run together on unimproved paspalum pasture for 10 months were found to depend on weather and were less than for similar ewes housed indoors and given a diet of high quality. On pasture, Lincoln, Corriedale and Polwarth fleeces lost considerable amounts of wax and suint owing to the 44½ in. of rain which fell during the trial. In Corriedale and Polwarth fleeces "canary" stain and bacterial discolouration showed during warm, wet weather. Severe weather affected the fine Merino least of the breeds studied.—J. C. Gill.

ASHTON, G. C., CATRON, D. V., HOMEYER, P. G., CURRY, N. H. and CULBERTSON, C. C. **Portable units for individual experimental pig feeding on pasture.** *J. Animal Sci.*, 1956, **15**, 307–314. [Dept. Statistics, Iowa Agric. Exp. Stat., Ames.]

An easily moveable unit with separate accommodation for 3 pigs is described. For each pig a pen 16 × 5 ft. with shelter and self-feeder is

provided. Statistical designs suitable for use with a number of the units are suggested.—T. D. Bell.

3885

HAELTERMAN, E. O. **Practical isolation equipment for baby pigs.** *Amer. J. Vet. Res.*, 1956, **17,** 129–131. [Purdue Univ. Agric. Exp. Stat., Lafayette, Ind.]

The equipment consisted of a galvanised can 26 in. high and 20 in. in diameter, with a wire bottom 5 in. from the base of the can. The unit was sealed with heavy cellophane and a rubber band. A feeding pan which could be filled by a tube and was covered with a hinged lid was let into the side of the can 2 in. above the wire floor and could be removed easily for cleaning. Air was changed by a fan which maintained a slight positive pressure within the unit. There was sufficient space between the wire floor and the bottom of the unit to collect excreta without changing for 2 or 3 weeks. The equipment was used for baby pigs 5 to 6 days old in studies of transmissible gastro-enteritis, and for pigs deprived of colostrum. It could hold pigs up to 3 weeks old. It was easy to clean and sterilise at the end of each experiment. Photographs show the construction and operation.

WHITEHAIR, C. K. and THOMPSON, C. M. **Observations on raising " disease-free " swine.** *J. Amer. Vet. Med. Assoc.*, 1956, **128,** 94–98. [Dept. Animal Husb., Oklahoma Agric. and Mech. Coll., Stillwater.]

In an attempt to rear disease-free pigs the litters were removed by caesarean section from 4 Chester White gilts, a few hours after the let-down of milk.

Twenty-three of the baby pigs were isolated and given a liquid milk diet until 5 weeks of age, after which a meal mixture was used. At about this time 9 pigs were fed for 28 days on the basal meal mixture supplemented with aureomycin, but their growth performances during this period were no better than those of 8 pigs given the basal meal mixture without antibiotic.

Seventeen pigs were reared successfully and grew at a rate equal to, or surpassing, the average rate of pigs reared by sows in the herd. At no time was there evidence of the diarrhoea or other disturbances which occurred at times in the foundation herd. Four ascarids were found in the intestines of 2 boars which were slaughtered, and it was believed that these had been acquired *in utero.*

Nine females were reared as breeding gilts, all farrowing one litter and 6 farrowing 2 litters. Of the first litters, 52 per cent. of the pigs born were weaned at an average weight of 27·2 lb. This poor performance was believed to be due to cold weather at farrowing, crowded farrowing quarters and possible deficiencies in the rations. Lactation results were above average for the herd. Of the second litters, 91 per cent. of the pigs born were weaned at an average weight of 30·4 lb.

LEWIS, C. J., CATRON, D. V., LIU, C. H., SPEER, V. C. and ASHTON, G. C. **Enzyme supplementation of baby pig diets.** *J. Agric. Food Chem.*, 1955, **3,** 1047–1050. [Iowa Agric. Exp. Stat., Iowa State Coll., Ames.]

In 3 experiments the effects of supplementing diets containing soya bean and milk protein with proteolytic enzymes were studied using 168 pigs with initial liveweights of 6 to 7 lb. and 16 pigs with initial liveweights of 28 lb.

A purified soya bean protein (Drackett C-1) containing 83·1 per cent. crude protein was used in the basal diets in all experiments. During the first experiment the addition of 20 per cent. lactose to the basal diet was of significant benefit to growth, and this amount was included in all basal diets subsequently.

Variation in response to enzyme supplements was too great to demonstrate statistical significance within each experiment, but when results from different experiments were combined there were significant increases of both rate of liveweight gain and efficiency of feed conversion when 1 per cent. pepsin and 1 per cent. pancreatin were added to the basal diets. The growth performances of pigs on positive-control basal diets containing 40 per cent. dried skimmed milk at the expense of the soya protein were significantly better than for pigs on the basal diets containing soya bean protein, and they were also better than for pigs on these soya bean protein diets supplemented with proteolytic enzymes.—I. A. M. Lucas.

JOUBERT, D. M. **An analysis of factors influencing post-natal growth and development of the muscle fibre.** *J. Agric. Sci.*, 1956, **47,** 59–102. [Sch. Agric., Cambridge.]

In each section literature is reviewed.

As a preliminary the effects on muscle fibre of fixation in formalin and of boiling, and the effect of eyestrain on the results when 100 fibres are

measured under the microscope are recorded. The effect of formalin is complete in 1 day and is less than that of heat. All the measurements described later are on formalin-fixed muscle. Measurements increased for each 20 fibres to 80 and, after a rest, dropped to the original level for the last 20. The differences from the general mean were not statistically significant, but with strain, selection of larger fibres does occur.

The muscles sampled were the longissimus dorsi, rectus femoris and gastrocnemius. The material was classified in 4 groups: (1) gastrocnemius of uncastrated males from pig, rabbit, sheep and cattle, at birth and maturity, for comparison of species; (2) from an experiment to compare steers of dairy breeds, and of the same breeds crossed with bulls of beef breed, so that breed and type could be studied with all variables associated with diet and management constant; (3) from an experiment with lambs in which plane of nutrition varied (see Abst. 3076, Vol. 22) and (4) from sheep killed at different ages and fed in different ways (see Absts. 1752, 3754, Vol. 18). Samples were procured from slaughterhouses also.

Briefly, the main results were as follows. Size of muscle fibre does not depend on size of animal species: those studied, in decreasing order of diameter of fibre, were pig, rabbit, cattle, sheep. Size at maturity increased with degree of postnatal development within the species studied. Fibre diameter was greater in Friesian steers than in crosses with beef breeds and least in purebred Dairy Shorthorn steers. There is no increase in number of fibres after birth. Sex differences are mainly referable to length, not diameter, of fibre, and muscles of wethers contain more fat than those of ewes of the same age. In lambs and mature ewes, fibre diameter rose with plane of nutrition with asymptotic limits at the upper level. Gastrocnemius had the largest fibres at birth and the smallest at maturity; longissimus dorsi smallest at birth and thickest at maturity. Fibres of low-plane animals at 290 days resembled those of high-plane animals at 60 days. Longissimus dorsi reacted most sensitively to plane of nutrition and would possibly provide the best criterion of muscle tissue in a carcase.—I. Leitch.

MEADE, R. J. **The influence of tryptophan, methionine and lysine supplementation of a corn-soybean oil meal diet on nitrogen balance of growing swine.** *J. Animal Sci.*, 1956, **15**, 288–296. [Nebraska Agric. Exp. Stat., Lincoln.]

Nitrogen metabolism data are presented for 24 male castrated pigs weighing about 32 kg. on a diet of ground yellow maize, soya bean oilmeal, dicalcium phosphate and iodised salt with a supplement of vitamins, antibiotics and trace elements. The diet contained crude protein 15·9, tryptophan 0·132, methionine 0·27 and lysine 0·69 per cent. In 3 separate experiments additions of tryptophan, methionine and lysine were made to bring the final level to 0·177 per cent. available tryptophan, 0·37 per cent. methionine and 0·84 per cent. lysine. In no case did the added amino acids improve N retention. The basal diet used appeared to contain protein in excess of requirement for pigs weighing over 40 g., evidenced by the increase in urinary N of pigs over that weight.

LENKEIT, W., GÜTTE, J. O., WARNECKE, W. and KIRCHHOFF, W. Langfristige Untersuchungen zum äusseren und inneren Stoffwechsel des graviden und laktierenden Schweines. 3. Die Beziehung der N-Retention während der Gravidität zum N-Umsatz nach der Geburt bei hoher Milchleistung und bei verhinderter Laktation. [**Prolonged studies of external and internal metabolism of pregnant and lactating sows. 3. Relation of nitrogen retention during pregnancy to nitrogen turnover after birth when milk yield is high and when lactation is prevented.**] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10**, 351–364. [Inst. Tierphysiol., Univ. Göttingen.] English summary.

For previous parts see Absts. 1248 and 2525, Vol. 26.

Two sows which had had a high protein intake during pregnancy were studied further: one suckled 12 piglets and her milk yield was estimated to be on the average 10·1 kg. daily for 59 days; the other sow had all 11 piglets removed at birth. Both sows received a ration (composition tabulated) rich in protein and total energy.

N retention in both sows increased during the course of pregnancy and the estimated total retention in 115 days of pregnancy was 1879·24 and 1265·78 g. The total losses at parturition were 340·98 and 289·75 g., leaving total increases of body N of 1538·26 and 976·03 g., of which 145 to 165 and 140 to 160 g. were ascribed to the enlarged uterus and mammary glands. The sow which suckled her young had a cumulative loss of N during 59 days of lactation of 1162·39 g.; the other lost in 35 days after parturition 647·46 g. N and then went into positive balance. During a period in which the young had diarrhoea and poor appetites the suckling sow secreted less milk, but lost more N in the urine; her negative N balance at this time became small. The negative N balance of the dry sow was due to a large N output in the urine, especially during the third to ninth days, when the mammary glands were regressing and appetite was poor. A castrated male pig pair-fed on the amounts of feed eaten by this sow from the 113th day of pregnancy to the 15th day

after farrowing was in negative N balance until the day corresponding to the 8th day after farrowing; initially his urine N was higher, but during the period of poor intake it was lower than that of the sow.

It is concluded that sows on protein-rich diet during pregnancy can store N in excess of that required for the products of pregnancy, and that this excess will be at least partly excreted afterwards even without production of milk.

NORDFELDT, S., OLOFSSON, N. E. and MÅNSSON, N. C. Försök med kommersiella kraftfoderblandningar för gödsvin. [**Experiments with commercial concentrate mixtures for fattening pigs.**] *Kgl. Lantbrukshögsk. Statens Husdjursförsök Särtryck* No. 110, 1955, pp. 16.

Three experiments were run with, in all, 8 groups of pigs of the Improved Swedish Landrace, totalling 102, fattened from 30 to 90 kg. liveweight. The cereal mixture was the same for both sets, the controls which had 2·5 kg. skimmed milk daily and the experimental pigs which had instead from 0·410 to 0·492 kg. of a commercial concentrate which was used according to instructions [composition not given]. In the first experiment the skimmed milk groups had chalk, salt and cod liver oil, in the second and third meatmeal, lucerne meal, chalk, salt and Deltafor D_3. The commercial concentrate provided all the supplements required with the cereal meals.

There was no significant difference in any test in rate of weight gain, loss at slaughter, feed units per kg. gain, body length, thickness of back fat or hardness of fat; 9 out of 10 in each lot reached the highest class for quality. Money cost of feed per kg. gain was slightly higher for the concentrate pigs in the second and third tests; but labour cost was greater for the milk pigs, so that there was little or no difference in cost of production.

MARTIN, J. and BUYSSE, F. La pomme de terre dans l'alimentation du porc. Comparaison entre les pommes de terre étuvées et les pommes de terre crues réduites en purée. [**Potatoes in pig feeding. Comparison of cooked and raw pulped potatoes.**] *Rev. Agric., Brussels*, 1955, **8**, 1135–1158. [Stat. Recherches État, Alimentation Bétail, Melle.] English and German summaries.

Earlier comparisons of raw and cooked potatoes for pigs are described and their results are summarised. This repeat was designed to test the effect of level of protein in the meal mixture, Lehmann system, and of mechanical pulping of the raw potatoes. Two meal mixtures were used, each with the same amount of barley, maize, milling offal, fishmeal, meatmeal, lucerne meal, minerals and cod liver oil, but one mixture had 20 per cent. of manioc and 4 of groundnut meal and the other 8 of manioc and 16 of groundnut so that the percentages of digestible crude protein were 14 and 20. There were 6 groups of pigs in pairs, 4 pigs in each group; each pig had 1 kg. daily of meal and potatoes, raw, pulped, or steamed and ensiled, to appetite. Two groups had in addition 2 litres skimmed milk daily. The tests lasted for 15 weeks and then for 3 weeks all had a diet of meals without potatoes.

Of each pair the pigs getting raw potatoes put on only about two-thirds as much weight as those getting steamed potatoes; they did a little better with 20 per cent. than with 14 per cent. protein and those with skimmed milk did best with each type of potato. Total weight gains in 15 weeks in g. [not kg. as printed in Table 8] per pig daily were: 20 per cent. protein meal, 407 and 663; 14 per cent. protein meal, 334 and 590; with skimmed milk, 478 and 796. Growth of the retarded pigs improved on meal alone. Cost of production was less with steamed potatoes.

3895

BECKER, M., OSLAGE, W. and FLIEGEL, H. Versuche über den Nährwert von Johannisbrot beim Schwein, insbesondere über die Beeinträchtigung der Eiweissverdaulichkeit durch die Gerbsäure des Futtermittels. [**Nutritive value of the carob bean for pigs, with special reference to the reduction of the digestibility of protein by the tannic acid of the feed.**] *Arch. Tierernährung*, 1955, **5**, 247–256. [Inst. Tierernährung, Brunswick, Völkenrode.]

The digestibility of carob bean protein with pepsin and HCl *in vitro* was nil, compared with fishmeal protein, 87 to 88 per cent. In mixtures of the substances the digestibility of the fishmeal protein decreased with increasing proportions of carob bean.

In digestibility trials pairs of pigs received rations containing two-thirds, half and one-tenth of the total as carob meal. The larger proportions of carob meal greatly reduced digestibility of the rest of the ration, especially that of protein. With 10 per cent. carob meal the reduction of digestibility was slight.—D. Duncan.

3896

GORB, T. V., PLYUSHCH, M. G. and SARZHEVSKII, N. V. Vliyanie razlichnyk dach kukurydzy na myasosalnuyu produktziyu svinei. [**Effect of feeding maize on fat production in pigs.**] *Veterinariya*, 1955, **32,** No. 10, 74–76. [Kharkov Vet. Inst.]

Three groups of 15 young pigs of average weight 66 to 69 kg. were fed on diets similar in nutritive value. There were 2 feeding periods. Group 1 (control) derived 50 per cent. of its energy from maize in the first period ; in the second period barley was substituted for maize. Group 2 derived 50 per cent. from maize in both periods and group 3, 75 per cent. The remaining constituents of the diet were barley bran, sunflower grist, steamed potatoes, sugar beet and clovery hay, the last being given only in the first period of feeding.

The average daily gains were 623, 530 and 631 g. and the average final weights were 141·0, 139·4 and 144·8 kg. for groups 1, 2 and 3, respectively. No feed was given for 24 hr. before slaughter. The average weights before slaughter were 135·2, 133·6 and 139·6 kg., and 2 hr. after slaughter 88·8, 89·3 and 93·7 kg.

A table summarises physical and chemical characteristics of meat in the 3 groups. Group 3 had the highest fat content and the highest iodine number. The average fat contents of carcases of the 3 groups were 29·52, 26·38 and 34·46 per cent. and the iodine numbers were 48·30, 52·40 and 55·40.

It is concluded that a diet containing 75 per cent. maize has no detrimental effect on fat production ; it tends to increase rate of weight gain and so allows profitable substitution of maize for other constituents of diet.—F. Billiewicz.

3897

DIAZ, F., SPEER, V. C., ASHTON, G. C., LIU, C. H. and CATRON, D. V. **Comparison of refined cane sugar, invert cane molasses and unrefined cane sugar in starter rations for early weaned pigs.** *J. Animal Sci.*, 1956, **15,** 315–319. [Iowa Agric. Exp. Stat., Ames.]

Baby pigs were fed from 2 to 8 weeks of age on a basal starter ration without sugar or with 5, 10 or 15 per cent. refined cane sugar or 5 or 10 per cent. sugar from invert cane molasses or combinations of these not exceeding 15 per cent. total sugar. One group received 15 per cent. unrefined cane sugar. As compared with the group receiving no sugar, rate of gain and feed efficiency increased with the 2 highest levels of refined sugar and with the unrefined sugar. Invert sugar alone failed to improve the performance of the pigs, and there was no additive effect when it was combined with refined sugar. The reasons for the performance with refined, as compared with unrefined, sugar are discussed. There was no undue scouring in any of the groups.—J. S. Thomson.

3898

OOSTHUIZEN, S. A., VERBEEK, W. A. and POTGIETER, T. D. **Food intake of baconers on pasturage.** *Farming in S. Africa*, 1956, **31,** 34–36. [Div. Animal Husb., Coll. Agric., Potchefstroom.]

Trials are reported from which it was estimated that pigs of about 200 lb. liveweight, on a young oat pasture, ate about 15·1 lb. green feed daily during an experimental period of 7 days. On a similar pasture, with 3 lb. of a concentrate mixture also, given daily, intake of green feed increased to 19·5 lb. On a young lucerne pasture the intake was 20·8 lb. These amounts do not supply enough total digestible nutrients for rapid growth.

SALMON LEGAGNEUR, E. and FÉVRIER, R. Les préférences alimentaires du porcelet. 1. Influence du mode de présentation des aliments : granulés ou farine. [**Feed preference in young pigs. 1. Effect of method of feed presentation : granular or as meal.**] *Ann. Zootech.*, 1955, **4,** 215–218. [Stat. Recherches Élevage, C.N.R.Z., Jouy-en-Josas.]

The study was made with 25 litters of Large White pigs. Each litter had the choice of the same feeds given as coarse granules or as fine meal and their daily intake was found by weighing. Four different feed mixtures were used ; one was given to 10 litters, 106 piglets, from 15 days to 1 month of age, the other 3 were each given to 5 litters from a month old until weaning.

The piglets always preferred the granular form to the meal and they ate from 3 to 13, mean 6·4, times as much of the former. One litter was exceptional and preferred meal.

It is suggested that the feed intake of young piglets may be increased by offering them feed in the coarser form so clearly preferred.—D. Duncan.

3900

KLAUS, W. Untersuchungen über den Einfluss von Penicillin und Aureomycin auf die Verdaulichkeit der Nährstoffe und die N-Retention bei Schweinen. [**Effect of penicillin and aureomycin on the digestibility of nutrients and on nitrogen retention in pigs.**] *Ztschr. Tierernährung Futtermittelk.*, 1956, **11,** 1–20. [Tierzucht-Inst., Univ. Kiel.] English summary.

In the first experiment the N balances of 2 almost fully-grown littermate gilts were studied ; in 3 successive periods of 27 days, with fore-periods of 10 or 12 days, the gilts received 2 kg. daily of a basal ration, and in the middle period each received in addition 1·82 g. Propentin, containing

10 mg. procaine penicillin and 10 μg. vitamin B_{12} per g. The mean daily gains in weight in the 3 successive periods were 324, 219 and 78 g. No effect of the supplement was detectable.

In the second experiment 12 castrated males from 4 litters of Saddleback pigs were used. The 4 groups received the basal diet alone, or with Aurofac all the time, or with Aurofac until they reached 50 kg. liveweight, or with Aurofac in 2 periods of 20 days. Balances were in 10-day periods. All the pigs given Aurofac made significantly greater gains in the first stage of growth and needed less feed per kg. weight gain, but in the second stage group 4 fell behind even the pigs given no Aurofac, and over the whole experiment they showed little advantage from the antibiotic supplement. The best results were in groups 2 and 3, and there was little advantage to be gained from giving Aurofac after the pigs reached 50 kg. liveweight. In the early stage Aurofac improved the digestibility of crude protein on the average from 68 to 76·5 per cent. and that of crude fat from 52 to 60 per cent., without much affecting the utilisation of the rest of the ration. N retention increased from 11·82 to 15·65 g. daily. In the later stages of growth this advantage disappeared.

In a third experiment 3 pairs of castrated males were used for a longer trial. They received, respectively, the basal diet alone and with 10 or 50 mg. aureomycin per kg. feed. This was given alone for 49 days and then mixed for 37 days with an equal proportion of barley meal and for the last 29 days with 2·2 parts of barley meal to each part of the basal diet. Balances were studied for the last 40, 24 and 18 days of these 3 periods. Another 3 pairs of castrated males were studied on the same diets for a shorter time. The pigs given the smaller amount of aureomycin grew less well than those given none, though the difference was small. The larger dose of aureomycin produced a slight improvement in daily weight gain and utilisation of feed in all 3 periods of the study. There was better digestibility of crude protein and fat with the larger dose of antibiotic in the first period, but not later; retention of N was not improved because more was lost in the urine. (See Abst. 3129, Vol. 26.)—D. Duncan.

3901

HANSON, L. E., HILL, E. G. and FERRIN, E. F. **The comparative value of antibiotics and arsonic acids for growing pigs.** *J. Animal Sci.*, 1956, **15**, 280–287. [Minnesota Agric. Exp. Stat., St. Paul.]

The effect of chlortetracycline, procaine penicillin, erythromycin, arsanilic acid, 3-nitro-4-hydroxyphenylarsonic acid and the first 2 antibiotics each with arsanilic acid was tested on growth of pigs from weaning to a weight of 200 lb. The ration was of yellow maize, soya bean oilmeal, tankage, linseed oilmeal, alfalfa meal, bonemeal, salt and a vitamin supplement. One group received no supplement. Over the whole experiment there was no significant difference in rate of growth between the control group and the groups receiving the antibiotics or the arsonic compounds or a combination of these. This is contrary to results previously reported (see Abst. 4381, Vol. 25), and is attributed to the higher quality of the pigs used in the present experiment. Efficiency of use of feed was best in the group receiving chlortetracycline, but the difference was only 5 per cent. over the control group. The arsenic content of the tissues depended on the level in the diet and was highest in liver and lowest in muscle. It was greatly reduced by stopping the arsonic compound a few days before slaughter.

J. S. Thomson.

3902

HÖPLER, E. Aurofac in der Schweinehaltung. [**Aurofac in pig feeding.**] *Bodenkultur*, 1955, **8**, 313–319.

A trial on a high-lying farm in Styria was made in the winter of 1953–54 with 3 litters (it was planned to have 6, but owing to severe weather 3 failed to reach satisfactory weight at weaning) of 8 pigs fattened for 120 days on potatoes, cereal mixture, flowering wild grasses, grass silage, minerals, cod liver oil and a protein concentrate. One litter (control) had dried skimmed milk 100, groundnut meal 75, soya bean meal 75 and fishmeal 100 g. per pig daily; the other 2 had dried skimmed milk 100, groundnut meal 150, soya bean meal 150 and Aurofac 3 g. In the control ration 38 per cent. of the crude protein was of animal origin, in the experimental, 13 per cent.; they had almost the same crude protein content. The sows were full sisters of an inbred strain of Large White and German Edelschwein ancestry, all mated to the same unrelated boar. The dams of the litters given Aurofac had had Aurofac, 6 g. daily for 70 days during suckling, and their piglets had had 0·25 per cent. Aurofac in their supplementary feed. Details of the rations, feed consumption and costs and monthly weights are tabulated.

The fattening pigs given Aurofac outstripped the others at first, but final weights were the same for both groups; the weights of those given Aurofac showed less scatter. The pigs given Aurofac ate less, total 212 kg. against 236 kg., and more economically, 3·36 kg. per kg. weight gain against 3·72 kg. With the additional saving from the use of the cheaper vegetable protein feeds, the respective costs were 3·81 and 4·42 Schilling per pig daily and 6·27 and 7·25 Schilling per kg. weight gain. The advantage far outweighed the cost of the Aurofac. It was concluded that the use of Aurofac is well worth while. Regular supply of small amounts,

i.e., careful mixing with the ration, is important. Aurofac for sows and piglets during the suckling period is also considered useful, as the litters grew more uniformly. There were almost no losses either with or without Aurofac, but unthrifty pigs (*Kümmerer*) did occur even when Aurofac was given.

BERTL, H. and TSCHIDERER, K. Schweinemastversuch mit "Aurofac-2A" bei Getreide-Magermilchfütterung. [**Pig fattening experiments with Aurofac 2A and a cereal and skimmed milk diet.**] *Bodenkultur*, 1955, **8**, 320–326. [Schweine-Versuchsanst., Landwirtschaftskammer Niederösterreich, Schwechat.]

In a trial in 1954, 2 groups of 8 piglets of the German Edelschwein breed, offspring of 2 sister sows mated with the same boar, received from 4 weeks of age a supplement of ground barley 58, ground oats 20, dried yeast 8, fishmeal 12 and minerals 2 per cent., and those of one group each had daily a teaspoonful, from 1·5 to 2 g., Aurofac-2A (Lederle, New York : guaranteed to contain at least 8 g. aureomycin per kg., and vitamin B_{12}, amount not guaranteed, with soya bean meal as carrier). After weaning at 8 weeks the pigs were penned in pairs and fed twice daily, but after 14 weeks of age not on Sundays, on the usual stock feed : ground maize 44, ground barley 44, lucerne meal 7, dried yeast 3, minerals 2 per cent. The minerals consisted of prepared chalk 62·5, decalcified bonemeal 20, iodised salt 15, ferrous sulphate 1·6, manganese sulphate 0·6, copper sulphate 0·3 per cent. The pigs also had from 1 to 3 litres sour (clotted) milk per pig daily, and each had 5000 I.U. vitamin D_3 weekly. The pigs of the experimental group continued to have the same daily supplement of Aurofac-2A for 8 weeks; the controls got the same amount of soya bean meal.

Over the first 54 days after weaning there was no difference between the groups in weight gain or feed consumption. It was concluded that the dose of aureomycin was too small and thereafter (from 46 kg.) 3 g. Aurofac-2A, *i.e.*, 24 mg. aureomycin, was given daily. For the next 66 days the mean daily gains were 881 g. with aureomycin and 836 g. without, for the same feed consumption, *i.e.*, aureomycin reduced feed consumption per kg. weight gain by 5·1 per cent. After this the pigs were sent to the veterinary college for 18 days for other studies and had no Aurofac-2A; 7 of each group were then killed at slightly over 100 kg. and the carcases were judged. Those of the pigs given Aurofac-2A had a lower ratio of fat to lean and a higher proportion of the more valuable cuts, and the quality of fat and lean was slightly better.

It was concluded that the use of Aurofac-2A is profitable even when feeding and management are excellent.—W. M. Deans.

SCHÜRCH, A. Verfütterung von Antibiotika und Futterverwertung beim Schwein. [**The use of antibiotics and feed utilisation by pigs.**] *Schweiz. Landwirtsch. Monatsh.*, 1956, No. 1, Sonderheft 60. Geburtstag Prof. Crasemann, 37–41. [Inst. Haustierernährung, Eidg. Tech. Hochsch., Zürich.]

A litter of 12 Improved Landschwein pigs was divided into 2 matched groups and fed for 20 weeks on a thick slop of cereals, skimmed milk and slaughterhouse waste; one group had 125 g. Aurofac 2A, supplying 1 g. aureomycin and 0·193 mg. vitamin B_{12} per kg. dry feed but had its feed intake restricted to that of the other group. Neither group grew well, possibly for reasons of heredity, but aureomycin gave 10 per cent. better weight gains and hence, under the conditions of this experiment, 10 per cent. better feed utilisation.

Literature on the mechanism of action of antibiotics is briefly discussed but it is considered that experimental results are too few for anything but speculation.—W. M. Deans.

JOHNSTON, E. F., ELLIS, N. R. and WINCHESTER, C. F. **The interaction of temperature and thiouracil feeding upon carcass characteristics and feeding characteristics of pigs.** *J. Animal Sci.*, 1956, **15**, 271–279. [U.S. Dept. Agric.]

In 5 experiments pigs were kept in cool environments between 45° and 68° F., or warm, 75° to 90° F., and in each temperature range 6 pigs were given a supplement of 0·15 per cent. thiouracil and 6 were untreated. In all but one experiment, in which the pigs were about 70 lb. liveweight, the liveweight was from 160 to 190 lb. The trials lasted from 28 to 32 days.

In the lower temperature range thiouracil gave thinner backfat, and increased the percentage of protein in the hams at the greater liveweights. The differences at the higher temperature were very small. Similarly, livers and thyroids were heavier in the treated animals, but less so in the warmer environment. Rate of gain and efficiency of feed use were improved by thiouracil at the lower but not at the higher temperatures, except in the experiment with pigs of 70 lb. liveweight, when the pigs untreated at the lower temperatures were better than those given thiouracil.

DAMMERS, J. Het gebruik van dikstrooisel voor varkens. [**Use of deep litter for pigs.**] *Landbouwvoorlichting*, 1955, **12**, 433–435. [Rijkslandbouwproefstat., Hoorn.] English summary.

Carse (*Agric. Gaz. N.S.W.*, December 1952) claimed that pigs on deep litter of sawdust and shavings grew faster than controls on a clean floor. Tests with 64 pigs of the Landrace type on ordinary rations of starter and fattening meals, sometimes with grain, buttermilk or whey, on deep litter of straw or on concrete, showed no difference in rate of weight gain or economy in 4 separate tests. Perhaps type of litter or environmental temperature may have affected the results.—I. Leitch.

JUCKER, H. Neuzeitliche Methoden der Schweinefütterung. [**Modern methods of pig feeding.**] Repr. from *Kleinviehzüchter*, April 1955, pp. 12. [Inst. Haustierernährung, Eidg. Tech. Hochsch., Zürich.]

This general article for the pig farmer includes suggestions for compounding protein concentrates and cereal mixtures on the farm, with particulars of the amounts to be given to sows and fattening pigs according as protein feeds and cereals are given separately or together and according as skimmed milk, buttermilk or curd is available or not. A mixture suitable for young pigs before weaning is also given. Other topics discussed include artificial rearing of piglets, methods of preventing anaemia, the use of vitamins and antibiotics, and methods of preparing and giving feeds.

FLOCH, H. A propos d'alimentation en Guyane Française. Elevage de porcs et arbre à pain. [**Nutrition in French Guiana. Pig rearing and bread-fruit tree cultivation.**] *Arch. Inst. Pasteur Guyane franç. Publ.* No. 383, November 1955, pp. 6.

In this general article a plea is made for the planting of species of bread-fruit tree, *Artocarpus incisa* and *A. integrifolia*, and of the palm *Astrocaryum vulgare*. It is thought that the produce of these trees, with fishmeal and leaves such as those of *Canavalia maritima* would provide feed in amounts sufficient to keep 20 pigs per hectare. Pig diseases are unlikely to provide difficulties. The pig meat would do much to overcome the shortage of animal protein in human nutrition.—D. Harvey.

KING, J. W. B. **Slaughter losses and yield of Wiltshire bacon.** *J. Agric. Sci.*, 1956, **47**, 23–28. [Animal Breeding Res. Organiz., Agric. Res. Counc., Edinburgh.]

A study was made of variations in the shrinkage from the live pig to the carcase and from the carcase to the unsmoked side of Wiltshire bacon.

Most of the variation was due to shrinkage from the live pig to the carcase. There were significant differences between litters and between breeds, Wessex and Essex Saddlebacks yielding 1·1 and 2.7 lb. more carcase weight at a given liveweight than Large Whites. To study the relations between yield of bacon and carcase characteristics, correlations were calculated between weight at slaughter, carcase weight and bacon weight and certain carcase measurements. Thickness of backfat and thickness of streak were negatively correlated with length of side and positively with each other. Carcase weight was positively correlated with all measurements, but to the greatest extent with thickness of back fat, thus indicating an antagonism between quantity and quality of bacon. This was also shown by a positive correlation between the proportion of desirable cuts and weight losses after slaughter.

There were differences between litters, but not between breeds, in shrinkage from the carcase to the bacon side. The correlations between yield of bacon and all carcase measurements except length were small and positive. There was no correlation between losses from the live pig to the carcase and losses in the curing process.

HETZER, H. O., ZELLER, J. H. and HANKINS, O. G. **Carcass yields as related to live hog probes at various weights and locations.** *J. Animal Sci.*, 1956, **15**, 257–270. [U.S. Dept. Agric.]

Backfat thickness was estimated at 150, 175, 200 and 225 lb. liveweight in 140 pigs, including boars, males castrated at 98 days of age (barrows), and gilts. At 150 lb. liveweight backfat was thickest in gilts and thinnest in boars, but by 225 lb. the order of thickness was barrows, gilts, boars. As liveweight increased, for all 3 classes of pig the positive correlation between backfat thickness measured on the live beast and that measured on the carcase increased. There was a significant negative correlation between live backfat measurements at all weights and the percentage of preferred cuts of the carcase. At the heavier weights measurements taken at the middle of the back were better than those at the shoulder or loin. For estimation of fat cuts, back fat measured at 225 lb. liveweight was most satisfactory, and the best location was the loin. This weight and location also gave the best prediction of percentage lean of hams.

KLIESCH, J. and BANKWITZ, E. Untersuchungen über die Beziehung zwischen Körperlänge und Speckdicke beim Schwein. [**Relation between**

body length and thickness of back fat in pigs.] *Zuchtungskunde*, 1955, **27**, 319–322. [Inst. Tierzücht., Tech. Univ., Berlin-Charlottenburg.]

In both Danish and Swedish bacon pigs length of body and thickness of back fat are inversely related and the probable error of the correlation coefficient is small. An analysis of the length and thickness of back fat in 816 German pork pigs, 50 to 110 kg. carcase weight, gave a significant positive correlation for the whole array, but negative correlations within 10-kg. weight classes individually that were significant only for the 3 top classes. Even then the probable error was so great that selection for length would not reliably select for leanness at the same time.—I. Leitch.

3913

JUCKER, H. Über die Abhängigkeit der Speckdicke vom Endgewicht und vom durchschnittlichen Tageszuwachs beim Schwein. [**Dependence of thickness of back fat on slaughter weight and average daily weight gain in pigs.**] *Schweiz. Landwirtsch. Monatsh.*, 1956, No. 1, Sonderheft 60. Geburtstag Prof. Crasemann, 42–46. [Inst. Haustierernähr., Eidg. Tech. Hochsch., Zürich.]

A statistical study was made of data for weight at slaughter, mean daily gains, length of carcase and thickness of back fat for 15 castrated male and 17 female pigs. When these 4 values were expressed by x_1, x_2, x_3 and y it was found that in male pigs

$$y = -3{\cdot}691 + 0{\cdot}268\,x_1 + 0{\cdot}0128\,x_2$$

and in females

$$y = +4{\cdot}317 + 0{\cdot}0200\,x_1 + 0{\cdot}0135\,x_2.$$

An equation using x_3 did not give a better result.

At all rates of growth female pigs may be expected to give a thinner layer of back fat than castrated males killed at the same weight. The results are too limited to have a general application. It is hoped to collect much more material.

D. Duncan.

PEARSON, A. M., BRATZLER, L. J., DEANS, R. J., PRICE, J. F., HOEFER, J. A., REINEKE, E. P. and LUECKE, R. W. **The use of specific gravity of certain untrimmed pork cuts as a measure of carcass value.** *J. Animal Sci.*, 1956, **15**, 86–92. [Dept. Animal Husb., Michigan Agric. Exp. Stat., East Lansing.]

Carcases of 103 pigs of different breeds, not reared under uniform conditions, were examined. Sp. gr. of untrimmed loin, ham and shoulder cuts and of whole carcases was estimated. When both loins, both hams or both shoulders were considered there was a highly significant correlation between sp. gr. of any untrimmed cut and the sp. gr. of the carcase. The correlations were slightly less when a cut from only one side was taken, and then the closest correlation was found between the ham and the whole carcase. When all pigs were considered the best indication of leanness of the carcase was from sp. gr. of the whole carcase or the untrimmed ham, but in pigs under 190 lb. liveweight a more accurate prediction could be made from thickness of backfat measured on the carcase or from carcase length.—T. D. Bell.

GOATS, RABBITS AND OTHER MAMMALS

3915

POTTS, C. G. and SIMMONS, V. L. **Milk goats.** *U.S. Dept. Agric. Farmers' Bull.* No. 920, revised October 1955, pp. 38.

3916

HOSKINS, L. W. and DALKE, P. D. **Winter browse on the Pocatello big game range in Southeastern Idaho.** *J. Wildlife Management*, 1955, **19**, 215–225.

For mule deer the most important plants were bitterbrush, mountain mahogany, big sage brush and juniper. In winter the elk were found mainly on high windy ridges, and depended largely on bunchgrass. There was direct competition between grazing cattle and elk, and elk and deer, but at existing controlled levels of stocking in the area investigated the competition was not serious.

T. D. Bell.

3917

MCCULLOCH, C. Y. (Jr.) **Utilization of winter browze on Wilderness big game range.** *J. Wildlife Management*, 1955, **19**, 206–215.

The vegetation and topography of the area and their history, as far as records allow, are described. Most of the browse is eaten by elk ; there are few deer. There were 10 sorts of shrubs available for browsing, but of these only 6 were eaten. The observations were complicated by the curiosity of the elk, which investigated all shrubs marked with plastic labels for the purpose of the survey, whether these types were usually eaten or not.

The available browse is now considered inadequate for the existing elk, despite the decline in their numbers in the last 20 years.—T. D. Bell.

ARGUTINSKAYA, S. V. and VOROB'EV, B. L. Izuchenie kormovykh svoistv treskovykh otkhodov. [**A study of the feeding properties of cod offal.**] *Karakul. i Zver.*, 1955, **8,** No. 3, 32–39. [All-Union Sci. Res. Lab. Fur Animal Husb.]

The digestibility of cod offal by young foxes was as good as that of horseflesh, and the use of cod offal with silkworm chrysalides made it possible to rear young foxes from the age of 2 to 2½ months without meat and without impairing the quality of the fur.—H. Scherbatoff.

3919

BELYAEV, V. N. Ispol'zovanie myasa stepnoi cherepakhi dlya kormleniya serebristo-chernykh lisits. [**The use of the meat of the steppe tortoise as feed for the silvery-black fox.**] *Karakul. i Zver.*, 1955, **8,** No. 3, 56.

Feeding foxes on tortoise meat was economically efficient, as it was cheaper than beef and saved a large number of cattle.—H. Scherbatoff.

3920

NORDFELDT, S., MELIN, G. and THELANDER, B. Smältbarhetsförsök med mink. [**Digestion experiments with mink.**] *Kgl. Lantbrukshögsk. Statens Husdjursförsök Särtryck* No. 114, 1955, pp. 14.

Part 1 of this report describes digestion experiments, each with 6 adult mink, made with the following feeds: codmeal alone or with, per cent. of the combination, 30 oatmeal, 30 wheat bran, 30 barleymeal, 60 cooked potatoes or 30 maizemeal, and offal (paunch) alone. Chromic oxide was used as indicator; there were 6 preparatory and 12 collection days with each feed. Analyses and digestibility coefficients are presented and nutritive values per kg. are given as follows, in g. digestible crude protein for fishmeal and offal and digestible true protein for the plant foods, digestible fat and digestible carbohydrate and metabolisable energy in Cal.: fishmeal 510, 106, 23 and 3170; oatmeal 74, 43, 414 and 2401; wheat bran 65, 34, 167 and 1267; barleymeal 31, 7, 501 and 2246; cooked potato —, —, 176 and 722; maizemeal 34, 31, 418 and 2142 and paunch 115, 58, — and 1011.

Part 2 deals with raw and toasted oatmeal and waste bread, their composition and digestion by 3 silver and 2 blue foxes in experiments with 7 preparatory and 14 test days. Oatmeal was heated in an electric oven at 100° and 200° C. for 45 min. and given with meatmeal and a standard ration of known digestibility. Heat significantly reduced the digestibility of crude protein and ether extract by both types of fox, 200° more than 100°. Heating at 200° C. almost completely destroyed vitamin B_1, reduced riboflavin to less than half, but did not affect nicotinic acid.

Similar experiments with 3 silver and 3 blue foxes showed that bread waste, chiefly of rye, is easily digestible and a more valuable feed than unheated oatmeal.—I. Leitch.

3921

LENSINK, C. J., SKOOG, R. O. and BUCKLEY, J. L. **Food habits of marten in interior Alaska and their significance.** *J. Wildlife Management*, 1955, **19,** 364–368. [Alaska Cooperative Wildlife Res. Unit, College.]

The food habits of the marten were found to be flexible. In the area studied the main foods were *Clethrionomys* and *Microtus*, followed by berries in the summer and birds in the winter. The choice is governed mainly by availability, and the search for food is the main activity in the marten's existence. In captivity martens accepted almost anything offered, and in traps they ignored pain and overruled fear when food was offered. The success of trapping is related to availability of food, for when not much is available the martens will always be easily attracted by bait.—T. D. Bell.

POULTRY

GROWTH AND FATTENING

3922

MUELLER, W. J., BOUCHER, R. V. and CALLENBACH, E. W. **Influence of age and sex on the utilization of proximate nutrients and energy by chickens.** *J. Nutrition*, 1956, **58,** 37–50. [Dept. Agric. Chem., Pennsylvania State Univ., University Park.]

From experiments with sheep and pigs the impression has arisen that digestion does not change with age. This is not confirmed with chicks. Metabolism experiments of 5 days' duration were made at 2 and 4 weeks of age and of 4 days at 7, 11 and 26 weeks on 5 groups of 15 male and 5 groups of 15 female New Hampshire chicks at the earlier ages and on 5 groups of 10 females only at 26

weeks. The ration was of the same composition throughout, cereals, soya bean oilmeal, fishmeal, alfalfa meal, dried whey, dried yeast, minerals and vitamins. Chromic acid baked with maizemeal and uniformly mixed was pelleted with the meal. Differences in digestibility between male and female were not significant. For both sexes together digestibilities of all organic constituents except fibre were highest at 4 weeks and least at 26 weeks; as a result metabolisable energy as a percentage of gross energy also was highest at 4 weeks. Daily weight gain and retention of protein were highest at 7 weeks. Percentage retention of crude ash declined sharply from 4 weeks. From these data percentage requirements of crude protein are estimated as 20 at 2 weeks, 21 at 4, 15 at 7, 12 at 11 and 11 at 26 weeks.—I. Leitch.

3923

3924

GORDON, R. S. and SIZER, I. W. **Ability of sodium sulfate to stimulate growth of the chicken.** *Science*, 1955, **122,** 1270. [Monsanto Chemical Company, St. Louis, Mo.]

Chickens were fed on a ration of casein 15, gelatine 10, maize oil 4, a salt mixture containing sulphates of Mn, Mg and Cu 6, vitamins and glucose to 100. The addition of sodium sulphate or sulphur to this ration did not improve growth rate, but when the sulphates of the mineral mixture were replaced by the chlorides or oxides, the addition of sodium sulphate improved growth rate and feed efficiency. Better growth was obtained by the addition of methionine or hydroxy analogues of methionine, but even large additions of these did not completely satisfy the total S requirement. Cystine, in a diet free from inorganic S, appeared to satisfy the requirement, provided methionine was not a limiting factor.—J. S. Thomson.

3925

BALDINI, J. T. and ROSENBERG, H. R. **The effect of productive energy level of the diet on the methionine requirement of the chick.** *Poultry Sci.*, 1955, **34,** 1301–1307. [Stine Lab., Grasselli Chem. Dept., E.I. du Pont de Nemours and Co., Inc., Newark, Del.]

When the percentage energy in a diet for chicks is increased, the percentage methionine must also be increased for the bird to get sufficient of the amino acid, since less feed is eaten. Trials were therefore made using diets of 800, 900 and 1000 Cal. per lb. The optimum percentage of methionine in the diet with 800 Cal. per lb. was 0·350, with 900 Cal. per lb. 0·399, and with 1000 Cal. per lb. 0·497. The relationship could be expressed by the equation

$$y = 0{\cdot}000736\,x - 0{\cdot}2269,$$

where y is the percentage of methionine and x the number of calories per lb. ration.—T. D. Bell.

3926

ROSENBERG, H. R., BALDINI, J. T., SUNDE, M. L., BIRD, H. R. and RUNNELS, T. D. **The concomitant use of fat and methionine in broiler diets.** *Poultry Sci.*, 1955, **34,** 1308–1313. [Stine Lab., Grasseli Chem. Dept., E.I. du Pont de Nemours and Co., Inc., Newark, Del.]

From 7 experiments at 3 different laboratories it was shown that the growth and feed efficiency of chicks to 8 or 10 weeks of age were improved by the addition of fat and DL-methionine alone or together to a basal ration. Fat was added at from 3 to 6 per cent., and methionine at 0·05 per cent. The response to methionine alone was slight; that to fat alone was greater. In combination the response was greater than would have been obtained had the effects been simply additive. At one centre feathering was poor with fat alone, but fat and methionine gave normal feathering.
T. D. Bell.

3927

FISHER, H. **The L-phenylalanine requirement of the chick.** *Arch. Biochem. Biophys.*, 1956, **60,** 108–114. [Rutgers Univ., New Brunswick, N.J.]

Chicks fed on a diet of wheat germ, gelatine and amino acids including excess tyrosine required 0·5 per cent. L-phenylalanine for growth and efficient use of feed. The rat requires 0·6 per cent. (Abst. 5257, Vol. 25). Since previous work with DL-phenylalanine showed a requirement of 0·9 per cent. (see Abst. 4713, Vol. 17) the D-isomer apparently was not used efficiently.—A. Hepburn.

3928

GRIMINGER, P., FISHER, H. and SCOTT, H. M. **On the arginine requirement of the growing chick.** *Poultry Sci.*, 1955, **34,** 1247–1249. [Illinois Agric. Exp. Stat., Urbana.]

In view of the divergent results obtained for the arginine requirement of chickens (see Abst. 1174, Vol. 20; Title 3023, Vol. 25) an experiment was made to find whether the browning reaction between carbohydrate and protein results in partial destruction of arginine in the ration, thereby increasing the apparent requirement. Day-old chickens were

reared to 3 weeks on a basal diet (22 per cent. casein) containing Cerelose or dextrin as the carbohydrate and either 1·25 or 1·75 per cent. arginine. Two further groups had the Cerelose added to the ration immediately before feeding.

There was no statistically significant difference in growth rate between the 3 high-arginine groups, and in each case average weights were above those of low-arginine counterparts. Neither Cerelose added to the rations before feeding, nor dextrin, which has a smaller number of reactive end groups than an equivalent amount of cerelose, had any sparing effect on the arginine requirement.

J. S. Thomson.

3929

WAIBEL, P. E., MORRISON, A. B. and NORRIS, L. C. **Production of depleted chicks by feeding maternal diets deficient in unidentified growth factors.** *Poultry Sci.*, 1955, **34,** 1322–1329. [Dept. Poultry Husb., Cornell Univ., Ithaca, N.Y.]

Eggs were obtained during 10 months of 1953–54 from White Plymouth Rock pullets of meat type kept on wire-mesh floors and mated with Barred Plymouth Rock cocks, and fed on a maize and soya bean oilmeal ration with minerals and vitamins (full details given), or the same with 3 per cent. condensed fish solubles and 3 per cent. dried whole liver replacing the same amount of soya bean oilmeal, to supply unidentified chick growth factors, or a purified diet of glucose (Cerelose), alpha-protein, hydrogenated fat, ground cellophane, DL-methionine and glycine, with minerals and vitamins, believed to be adequate in known nutrients only.

The chicks were reared on wire-mesh floors in groups generally of 18 to 20 of both sexes, on a basal purified diet of the same constituents as before in slightly different proportions, given to appetite, or the same supplemented with a mixture of dried whole liver, maize distiller's dried solubles, fish solubles, dried whey product and grass juice, or a mixture with penicillin mycelia meal instead of the dried liver [errors in statements of these mixtures].

So far as the hens were concerned the purified diet did not affect fertility or hatchability of eggs, but number and weight of eggs were reduced. The hens given fish solubles and dried liver did no better than those not given this supplement.

The mean chick weights in g. at 4 weeks were : chicks from hens on purified diet, on basal purified diet 298, with supplement 407 ; from hens on maize and soya bean ration, 312·5, 422 ; from hens on maize and soya bean ration with fish solubles and dried liver, 333, 423. In the first 2 sets of chicks, but not the third, the effect of the chick supplement was much greater in male than in female chicks. Most feed per g. gain was required by chicks from hens on purified diet, on basal purified diet ; when the chick supplement was given, feed efficiency did not vary with the hens' ration.—W. M. Deans.

3930

SCOTT, H. M., MORRISON, W. D. and GRIMINGER, P. **Studies on unknown growth factors in distillers dried solubles.** *Poultry Sci.*, 1955, **34,** 1446–1447. [Illinois Agric. Exp. Stat., Urbana.]

Previous results of Norris and of Couch *et al.* (*Proc.* 10th *Distillers Feed Conference* (1955)) and of Morrison (Abst. 1290, Vol. 26) suggested that part of the growth response of chickens to distiller's solubles might be attributed to the ash content.

Experiments now reported showed that although a growth response was obtained by the addition of 10 per cent. distiller's solubles alone, or along with the ash derived from this amount, to a basal diet, there was no response to the ash alone. Reasons for the divergent results are discussed.

J. S. Thomson.

3931

EDWARDS, H. M. (Jr.), CHIN, D., NORRIS, L. C. and HEUSER, G. F. **Differentiation of unidentified chick growth factors in liver.** *J. Nutrition*, 1955, **57,** 329–343. [Agric. Exp. Stat., Cornell Univ., Ithaca, N.Y.]

A purified diet was used, amply supplied with minerals, including trace elements, and all vitamins known to be required. The following supplements gave increases in rate of growth : defatted dried liver, fish solubles, the 2 together (cumulative effect). Fractions of liver were then tested, a concentrated aqueous extract of fresh liver, the residue, and fractions 1 and 2, 1 prepared from the concentrate by extraction with 70 per cent. ethanol and concentration, and 2 the residue from this extraction. Residue had no effect on growth, concentrate and both fractions were active, 1 more than the others. This fraction was then extracted with phenol, the phenol was dissolved in ether and the active substance was removed by washing with water. Here the phenol-soluble fraction was active, the residue without effect. The active extract was further analysed by counter-current distribution, with equal parts of phenol and butanol against water with glacial acetic acid to give a p_H of 2·5. This showed that the original phenol extract contained at least 2 unknowns, one soluble in the phenol-butanol solvent and apparently organic and the other water-soluble and probably inorganic. Results in successive experiments were not consistent.

There was also an unknown in fish solubles.

MORIMOTO, H., ARIYOSHI, S. and HOSHII, H. **Comparison of some sources of unidentified chick growth factors with fish meal.** *Poultry Sci.*, 1955, **34,** 1392–1395. [Nat. Inst. Agric. Sci., Chiba, Japan.]

The following products were tested for effects on growth of day-old chickens : water-soluble fraction of sardine meal and residue, autolysed sardine solubles and residue, solubles prepared in the usual manner, autolysed cuttlefish, wood yeast, brewer's yeast, fungi feed (mould culture from distiller's residue), and Koji feeds (mould culture from starch cake and ammonium sulphide) containing differing amounts of vitamin B_{12}.

Although most of the fish products had a growth-promoting effect, none equalled that from sardine meal. Of the microbiological products, wood yeast, brewer's yeast and some of the Koji feeds had an effect similar to the sardine meal ; fungi feed had less effect.—J. S. Thomson.

3933

OLOUFA, M. M. **Effect of thyroprotein on the growth of Egyptian baby chickens.** *Poultry Sci.*, 1955, **34,** 1292–1294. [Coll. Agric., Univ. Cairo.]

Addition of 10 g. thyroprotein per 100 lb. ration to the diet of 7-day-old Egyptian chickens greatly depressed growth to 12 weeks. Addition at the rate of 5 g. per 100 lb. also depressed growth, but here the difference was not significant. Mortality at the higher level of intake was 22 per cent. higher than that of controls ; at the lower level, 6·5 per cent. higher.—J. S. Thomson.

3934

BIELY, J., MARCH, B. E. and TARR, H. L. A. **The nutritive value of herring meals. 3. The effects of heat treatment and storage temperature as related to oil content.** *Poultry Sci.*, 1955, **34,** 1274–1279. [Poultry Nutrit. Lab., Univ. British Columbia, Vancouver.]

For previous parts see Abst. 5514, Vol. 24.

Herringmeal prepared in the laboratory by a low-temperature process was used in chick starter mashes. Some of the meal was used without extraction and contained about 7·5 per cent. fat. Another lot was extracted with hexane, giving a meal with about 0·2 per cent. fat. A third lot of meal was extracted, but fresh herring oil was added to restore the fat content to the level of that of the unextracted meal. From each of these 3 lots of meal a ration was prepared in which the meal was unheated or heated for 1, 2 or 3 hr. at 149° C. When included as 18 per cent. of a starter mash for day-old chicks growth was retarded at 10 days of age by the unextracted meal heated for 2 hr. and all meals heated for 3 hr. Growth rates were equal with the unheated meals, and the addition of fresh herring oil gave no improvement over the other rations. In this experiment the basal ration was low or marginal in folic acid.

In a second experiment, to test the hypothesis that the poor growth on heated meals might be due to the destruction of folic acid, a basal mixture deficient in vitamins was used. To it were added heated and unheated meals and oils, with or without a vitamin mixture. With added vitamins growth was equal on all rations, but on the deficient diet both heated and unheated oils depressed growth.

With commercial meals it was found that folic acid was less stable during storage in meals extracted with hexane than in unextracted meals.

3935

KURNICK, A. L., REID, B. S., SVACHA, R. L. and COUCH, J. R. **Effect of dried whey on growth, egg production and hatchability.** *J. Nutrition*, 1955, **57,** 345–352. [Dept. Poultry Husb., Texas Agric. and Mech. Coll. System, College Station.]

At 67 days of age chicks reared on a practical diet of ground yellow maize, soya bean oilmeal and vitamins and minerals were divided into 2 groups, each of 163 birds, and given a purified diet with all known requirements met and containing penicillin, 33 mg. per kg. feed. The second group had 4 per cent. of sucrose replaced by dried whey. At 143 days of age all had been transferred to individual cages for the laying test. After 12 weeks, the group without whey was divided into 2 subgroups of which one was given 4 per cent. of whey. In a second similar experiment with 135 chicks the age of transfer to the purified diet was 86 days and to laying cages 132 days of age.

Whey gave significantly better growth, earlier sexual maturity (94·8 per cent. in egg production at 175 days as against 62·2 per cent. without whey), more eggs, and better hatchability than no whey, but hatchability was not normal in either group.

I. Leitch.

3936

SCHLAMB, K. F., CLAGETT, C. O. and BRYANT, R. L. **Comparison of the chick growth inhibition of unheated linseed hull and cotyledon fractions.** *Poultry Sci.*, 1955, **34,** 1404–1407. [Dept. Agric. Chem., N. Dakota Agric. Exp. Stat., Fargo.]

Three trials are reported to determine the nature of the growth-depressing substance in raw linseed meal, previously attributed to several causes, including the development of a deficiency of some component of the vitamin B complex or to the contained mucilage. Flax seed was separated by a method described into hull and cotyledon fractions, and these were incorporated into a basal

ration for chickens of soya bean oilmeal, maizemeal, vitamins and minerals. Other groups were given a commercial linseed meal, an unheated meal extracted with light petroleum or a heated meal.

In all experiments growth was best on the basal ration, followed by groups on the linseed hulls, indicating that the mucilage was not the cause of the growth-depressing effect of linseed meal. The cotyledon fraction and the unheated meals produced poor growth.—J. S. Thomson.

3937

HEYWANG, B. W. and BIRD, H. R. **Relationship between the weight of chicks and levels of dietary free gossypol supplied by different cottonseed products.** *Poultry Sci.*, 1955, **34,** 1239–1247. [Agric. Res. Serv., U.S. Dept. Agric., Animal and Poultry Husb. Res. Branch, Glendale, Ariz.]

Different cottonseed meals raw, screw-press, hydraulic, solvent-extracted or pre-press solvent-extracted, partly or completely replaced soya bean meal in a control diet so as to supply from 0·008 to 0·075 per cent. of free gossypol. In one experiment pure gossypol was given and in some DL-lysine was added to determine whether part of the gossypol was inactivated by lysine. Day-old New Hampshire and White Leghorn chicks were given the diets to 5 or 6 weeks.

Growth in all cases was best on the soya bean meal ration, and curves are presented to show the decrease in final weight as the amount of free gossypol rose, particularly when raw cottonseed meal was used. DL-Lysine did not inactivate free gossypol. It is concluded that the free gossypol of the ration should not exceed 0·016 per cent. for White Leghorns or 0·020 per cent. for New Hampshires.—J. S. Thomson.

3938

ALMQUIST, H. J. and MERRITT, J. B. **Whole barley compared to hulled barley for turkeys on range.** *Poultry Sci.*, 1955, **34,** 1449. [The Grange Co., Modesto, Calif.]

On a limited mash intake turkeys on range consumed less hulled than whole barley, the ratio being 0·86, a ratio equivalent to the inverse ratio of the productive energy value of these grains. On a free choice mash and grain system much more of the hulled than of the whole barley was eaten, the former to the extent of 37 per cent. of the ration as compared with a voluntary intake of 15 per cent. whole barley under similar conditions.

J. S. Thomson.

3939

FANGAUF, R., KLEIN, K. W. and BARLÖWEN, G. v. Weizenkleie und Weizenfuttermehl im Küken-Alleinfutter. [**Wheat bran and wheat feed in all-mash rations for chicks.**] *Arch. Geflügelk.*, 1956, **20,** 24–34. [Lehr- u. Versuchsanst. Kleintierzucht, Kiel, Steenbek.] English summary.

Each of the 8 rations compared contained, per cent., fishmeal 6, soya extraction meal 6, lucerne leaf meal 2, dried yeast 3 and minerals 3. The other 80 per cent. was made up of different proportions of maizemeal and whole wheat meal, wheat bran and wheat middlings. Each ration was given to 30 day-old chickens for 8 weeks. Feed intake and weight gain were studied weekly.

The greatest feed intakes and weight gains were on 2 diets containing 60 per cent. of a mixture of maizemeal and whole wheat meal, one with 20 per cent. bran and the other with 20 per cent. middlings. With 80 per cent. of the maizemeal and wheatmeal mixture the intake was less, but growth was as good; use was more efficient. Growth was impaired when the proportion of maizemeal and wheatmeal mixture fell below 40 per cent.

It is concluded that 50 per cent. of ground grain is sufficient for chick mashes and that they should contain not more than 15 per cent. of bran or 30 per cent. of wheat by-products.

CASTLE, M. E. and KING, J. O. L. **Fodder-beet for fattening ducks.** *Empire J. Exp. Agric.*, 1955, **23,** 251–256. [Dept. Animal Husb., Fac. Vet. Sci., Univ. Liverpool.]

In each of 6 trials with ducks 3 weeks old, one group was fed on meal only, as much as the birds would clean up in 3 feeds a day. This meal contained 18·7 per cent. crude protein. Another group was given 126 g. of a meal with 25·6 per cent. crude protein, and minced fodder beet to appetite. The birds were weighed weekly and killed at 9 weeks of age. The birds receiving meal only were on the average 12 per cent. heavier at the end of the experiment, a result which was statistically significant. Dressing percentages were not significantly different. The birds getting fodder beet ate 44 per cent. less meal than those getting meal only, but their meal was more costly. It was calculated that 2·98 g. beet replaced 1 g. meal. Accurate costings of the trials were not made, but the possible economies of replacing some of the meal for fattening ducks by fodder beet are discussed.—T. D. Bell.

3941

KRÜGER, L., LÖTHE, E. and SEEFELDT, G. Aufzucht-Versuch mit gepresstem Küken- und Junghennen-Alleinfutter. [**Rearing experiments with pressed all-mash for chicks and pullets.**] *Arch. Geflügelzucht Kleintierkunde*, 1955, **4,** 190–192. [Inst. Tierzucht, Justus Liebig Hochsch., Giessen.]

Of 4 groups of 40 day-old chickens, 2 groups were Leghorn × Rhode Island and 2 groups the reciprocal cross. One group of each cross had a standard ration with green feed, carrots and cod liver oil, the other had the pressed mash ration and carrots.

There was little difference in growth at first, but after 20 weeks the Leghorn × Rhode Island group given the pressed mash were 11 per cent. heavier than those on standard feed ; in the other 2 groups the difference was only 1 per cent. In both crosses utilisation of the pressed mash was poorer in the first 8 weeks, but later it was better than that of the standard ration. Over the whole 20 weeks the pressed mash was 5 per cent. better in this respect.

The composition of all the rations is tabulated in full.—D. Duncan.

3942

GUTTERIDGE, H. S. and NOWOSAD, F. S. **Pasture for poultry.** *Canada Dept. Agric. Publ.* No. 771 (revised) August 1955, pp. 16.

The value and importance for poultry of pasture as a source of vitamins, protein and minerals is discussed. Expensive feedingstuffs are saved. The management of annual and perennial pastures, with suitable crops for each, is described. The former have the advantage of being freed from parasites by constant attention and cultivation, but they are more expensive to maintain. In Canada oats is the most common crop. Perennial pastures, on the other hand, take their place in the farm rotation. With proper management the time elapsing between periods when poultry are folded on perennial pastures is long enough for the danger of parasites to be avoided. Grass and legume mixtures are recommended. Both types of pasture should be located well away from breeding houses, so that the young birds on pasture are not in contact with the older stock. Details of both types used successfully in the experimental farms in the different provinces of Canada, and their cultivation, are described.

Soilage crops, dried grass meal, silage and lawn clippings for poultry are discussed.—T. D. Bell.

3943

RUBIO PAREDES, J. Aprovechamiento del micelio de la fabricación de penicilina en la alimentación de aves. [**Use of penicillin mycelium in the feeding of birds.**] *An. Ins. Farm. Esp.*, 1954, **3,** 341–357.

From analysis of 50 samples of dried penicillin mycelium, the mean composition, per cent., was moisture 3·4, crude protein 31·3, crude fat 4·6, N-free extract 22·2, crude fibre 9·7 and ash 28·8. The mean riboflavin content was 40·25 μg. per g.

Four groups of 57 day-old chickens received a basal diet of, per cent., maizemeal 40, barleymeal 12, oatmeal 15, wheat bran 10, groundnut cake 8, fishmeal 10, alfalfa meal 3, chalk 1 and bonemeal 1. The supplements, each given to one group, were procaine-penicillin G, 5 g. per ton ; Aurofac, 2·5 kg. per ton ; and dried mycelium, 5 per cent. All groups had a vitamin supplement. The chickens were kept on wire floors and fed to appetite. Each of the supplements gave better growth in 7 weeks than the basal ration alone ; the improvements were 17·9, 18·9 and 8·5 per cent., respectively. The number of deaths was least with mycelium.

It is suggested that a combination of penicillin and mycelium would be valuable in rations for chickens.—D. Duncan.

3944

AMSCHLER, J. W. and PAMMER, H. Entenmastversuch mit Bi-Con TM_{3+3} (Terramycin). [**Duck fattening experiment with terramycin.**] *Bodenkultur*, 1955, **8,** 327–330. [Inst. Tierzucht, Hochsch. Bodenkultur, Vienna.]

Three hundred Pekin ducklings were fattened for 8 weeks on a mixture of ground maize and barley 40, wheat bran and oat flakes 32, animal protein (dried skimmed milk and fishmeal) 13, vegetable protein (ground soya and pumpkin cake and dried yeast) 12, and minerals (chalk and wood charcoal) 3. The feed contained crude protein 18·7, digestible protein 15·2, crude fibre 6·4 and total nutrients 65·4 per cent. and the ratio of protein to total nutrients was 1 : 4·2. The feed was given twice daily in a moist crumbly state. The ducklings had access to drinking water. Half of them had, per metric ton feed, $3\frac{1}{3}$ lb. (1·51 kg.) Bi-Con Tm_{3+3} (Pfizer Co., New York), supplying 10 g. terramycin and 10 mg. vitamin B_{12} [the percentages given at the foot of p. 327 are wrong] with soya bean meal as carrier.

The ducklings given terramycin and vitamin B_{12} made better weight gains, especially in the first 3 weeks ; over the whole period 7·1 per cent. better, with less feed. The overall improvement in feed efficiency assessed by Lehmann's method was 7·7 per cent. Losses were fewer. The flesh of the birds was pure white and of excellent quality.—W. M. Deans.

3945

NOWAK, H. Entenmast mit Terramycin und Vigofac. [**Fattening ducks with terramycin and Vigofac.**] *Arch. Geflügelk.*, 1956, **20,** 35–40. [Inst. Tierzucht, Hochsch. Bodenkultur, Vienna.] English summary.

There were 4 groups, each of 240 Pekin ducks, fattened from one-day-old for 8 weeks. They received standard rations throughout, with a change to the finishing ration after 4 weeks.

Group 1 had no addition ; group 2 had terramycin, 22 g. per metric ton in the first ration and 11 g. in the second ; group 3 had Vigofac, 9 lb. and then 4·5 lb. per ton ; group 4 had both terramycin and Vigofac at the same rates.

Feed intake was almost the same in all 4 groups. Relative weight increases in order from group 1 to 4 were 100, 105·7, 106·0 and 110·9. Relative feed requirements per unit weight increase, in the same order, were 100, 92·5, 91·7 and 89·8. Losses in all 4 groups were small, 2, 1, 1 and 3 ducks, respectively.—D. Duncan.

3946

AMSCHLER, J. W. Terramycin in der Fütterung des Geflügels. [**Terramycin in the feeding of poultry.**] *Bodenkultur*, 1955, **8,** 307 – 312. [Inst. Tierzucht, Hochsch. Bodenkultur, Vienna.]

3947

GERRIETS, E. Aureomycin ad us. vet. als Futtersupplement in der Kükenaufzucht. [**Aureomycin for veterinary use as a feed supplement in chick rearing.**] *Berl. Münch. tierärztl. Wochenschr.*, 1956, **69,** 9–13. [Abt. Geflügelkr., Humboldt Univ., Berlin.] English summary.

Three trials were made in 1955 with veterinary aureomycin, each with 2 groups of 100 chickens reared intensively indoors to 8 weeks on a mixture of ground wheat 50, ground oats 10, ground maize 13, soya grits 15, dried skimmed milk 5, dried yeast 3, vitamin mixture (bran coated with cod liver oil fortified with vitamins A, D_2 and E) 0·5, minerals 2·5, wood charcoal 1 per cent. Trials 1 and 2 were with Italian chicks on sawdust regularly changed under conditions resembling those of a well-run poultry farm ; trial 3 with Rhode Island chicks on old horse litter which was not changed, and under severe conditions in open-fronted pens. In each trial one group had 10 mg. aureomycin per kg. feed, mixed in by machine.

In trial 1, the group given aureomycin made significantly better weight gains ; in the other 2 trials there was no significant difference. Losses were few but aureomycin did not reduce them. From these results and those of other experiments by the author, it is concluded, contrary to the findings of others, that aureomycin at the rate of 10 mg. per kg. feed is useless ; and undesirable because of the risk of impairing its therapeutic effect. Evidence in favour of aureomycin comes mostly from the United States where conditions are different, *i.e.*, broilers are reared in such large groups that hygiene suffers and antibiotics therefore show an effect. Use of aureomycin in Germany should be legally restricted to fattening mixtures and its presence should be declared, as is done in Switzerland and the Netherlands.—W. M. Deans.

3948

SLINGER, S. J. and PEPPER, W. F. **Effect of water intake on the growth response of poults and chicks to penicillin.** *J. Nutrition*, 1955, **57,** 319–328. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

There were 8 groups each of 10 male and 10 female Broad Breasted Bronze poults and 4 groups each of 20 crossbred male chicks. Parallel reserves provided replacements for those that died. The diets, detailed, were of grain, soya bean oilmeal, tallow (poults), soya bean oil (chicks), dried grass, meatmeal, fishmeal, dried buttermilk, minerals and vitamins, including vitamin B_{12}, 3 mg. per lb. feed. Weight and consumption of feed and water were recorded daily for 14 days (poults) or 28 days (chicks). Groups of poults were in pairs, with and without penicillin, 25 mg. per kg. feed, 4 allowed to eat to appetite and 4 with their allowances equated to one or other of these latter groups ; of each of these series of 4 groups, 2 had water to appetite and 2 equated. There was no difference referable to water in response to penicillin. With the chicks, which were fed to appetite, there was no significant response to penicillin and no effect of amount of water taken.—I. Leitch.

3949

LINDBLAD, G. S., HUNSAKER, W. G. and AITKEN, J. R. **The influence of penicillin, aureomycin and 3-nitro-4-hydroxyphenylarsonic acid on the growth of goslings.** *Poultry Sci.*, 1955, **34,** 1259–1261. [Poultry Div., Central Exp. Farm, Ottawa.]

Two experiments are reported. In the first neither penicillin, 25 p.p.m., nor 3-nitro-4-hydroxyphenylarsonic acid, 50 p.p.m., added to a basal ration improved growth rates or efficiency of feed utilisation of goslings up to 4 weeks old. In the second the same supplement of arsonic acid and supplements of 25 or 100 p.p.m. penicillin or aureomycin were compared with the basal ration. In this experiment growth was improved up to 2 weeks old by 25 and 100 p.p.m. penicillin and 100 p.p.m. aureomycin, but by 5 weeks of age the advantage had disappeared.—T. D. Bell.

3950

KEELING, A. D., HILL, C. H., GARREN, H. W. and KELLY, J. W. **The effect of chlortetracycline and fish meal on the growth and thyroids of chickens.** *Poultry Sci.*, 1955, **34,** 1453–1454. [Dept. Poultry Sci., N. Carolina State Coll., Raleigh.]

Groups of day-old chickens were fed for 34 days on an all-vegetable diet or one containing 5 per cent. fishmeal, other groups on the same diets plus 100 mg. chlortetracycline per lb. Thyroid glands were removed, weighed and examined histologically.

Chlortetracycline had a significant effect on weight gains in the all-vegetable diet group, but with fishmeal there was none. The antibiotic had no significant effect on size or histological appearance of the thyroid. The glands of the all-vegetable group were slightly larger and more active than those of the fishmeal group, owing possibly to the iodine in the fishmeal.—J. S. Thomson.

3951

ADAMS, J. L. **The effect of ration, caponizing, and hormone treatment on broiler strain New Hampshire cockerels.** *Poultry Sci.*, 1955, **34,** 1295–1297. [Poultry Dept., Univ. Wisconsin, Madison.]

Cockerels of a modern broiler strain, New Hampshires, were divided into 3 groups: (1) surgically caponised at 6 weeks, (2) implanted with a 15-mg. pellet of diethylstilboestrol at 12 weeks and (3) untreated. One-half of each group was fed to 16 weeks on a ration in use in 1935 and the other on a modern broiler ration in use in 1951 to determine the improvement in feeding, and the results were compared with those reported in 1936 for heavy breeds.

The modern strain on the modern broiler ration weighed, on the average, 5·48 lb. at 16 weeks; the corresponding weight for the same strain given the old ration was 4·56 lb.; the heavy breeds reared in 1936 weighed only 3·68 lb. at the same age.

In comparison with untreated cockerels, surgical caponising did not affect the rate of growth of the modern breed on the modern ration, but on the old ration this treatment produced a 13 per cent. increase in growth. Implantation produced increases of 10 and 12·5 per cent. on the new and old diets, respectively, and improved conformation and finish. The economics of the problem are discussed.—J. S. Thomson.

3952

BRESSLER, G. O. **Confinement rearing of pullets in Penn State experimental poultry house.** *Pennsylvania Agric. Exp. Stat. Progr. Rep.* No. 140, September 1955, pp. 4.

An experimental poultry house 30 × 100 ft. is described which has been used for rearing and laying pullets. Details of the method of changing over are given. The cost of labour and electricity for the brooders, and the mortality, were low, and efficiency of feed conversion was high.—T. D. Bell.

EGG PRODUCTION

3953

WEBER, F. and LE ROY, H. L. Wechselwirkungen zwischen Erbgut und Umwelt beim Haushuhn und ihre Bedeutung für die Umweltgestaltung bei Leistungsprüfungen. [**Interactions of heredity and environment in the domestic fowl and their bearing on the control of environment in tests of production.**] *Arch. Geflügelk.*, 1956, **20,** 1–14. [Versuchsgut Chamau, Eidg. Tech. Hochsch., Zürich.] English summary.

Although the possibility of interactions of heredity and environment is generally admitted, their existence has been demonstrated in only very few studies on domestic animals.

In the present paper hens in an egg-laying test made at the experimental farm of Chamau in 1954–55 and reported elsewhere (Weber, *Der Geflügelhof*, 14 October 1955) were compared with their full sisters in the flocks from which they came, for number of eggs from onset of laying to 9 January, egg weight in December, and body-weight at 10 weeks of age. From each of 4 flocks 70 unsexed chicks selected at random were sent for test. Owing to deaths, failure to lay, missing heredity data and exclusion of hens which had not at least 3 full sisters for comparison, correlations were worked out only for 22, 25 and 25 hens from 3 flocks. These were compared with theoretical correlations calculated from the heritabilities of the 3 characteristics as found from all the available data for each flock separately. From the differences found it was concluded that interaction of heredity and environment probably exists for weight at 10 weeks considered as a measure of early maturity, in agreement with the results of Skaller and Sheldon (*Austral. J. Agric. Res.*, 1955, **6,** 171), is not probable for number of eggs, and requires further investigation for egg weight. The results show the importance of conducting tests in an environment similar to that in which the birds or their descendants are likely to be kept.

W. M. Deans.

3954

MANTEL, K. Einfluss von verschieden hohem Getreideanteil im Alleinfutter auf Legeleistung, Zuchterfolg und Wirtschaftlichkeit der Fütterung. [**Effect of different levels of grains in an all-mash ration on egg yield, breeding and economics of feeding.**] *Arch. Geflügelk.*, 1956, **20,** 15–23. [Geflügelzuchtlehranst., Erding, Obb.] English summary.

Results of a previous experiment (Abst. 4438, Vol. 25) with different levels of grains in a mixed ration are briefly recapitulated, and a similar 350-day experiment made in 1954–55 with an all-mash ration and 3 groups each of 30 Leghorn and 30 Italian pullets is reported. Coarsely ground grains, equal parts of wheat, maize, barley and oats, formed 45, 60 or 75 per cent. of the ration; equal parts of wheat bran and pollards made up 30, 15 or 0 per cent., and the other items were Maizena 8, malt sprouts 3, herring meal 4, meatmeal 3,

dried skimmed milk 1, yeast 1, lucerne meal 3 and DLG mineral mixture Ia 2. Of this 15 g. per bird daily was given in a moist crumbly condition, the rest dry to appetite. In December and January 1 g. cod liver oil or 8 g. carrot silage per bird daily was given, week about. In winter the birds had a 12-hr. day, and they were let out every second day, weather permitting.

As before, total number of eggs, number of eggs produced in winter, egg weight, number of birds qualifying for recording and efficiency of feed utilisation all increased with the percentage of grains in the ration. With 45 and 60 per cent. grain the Leghorns laid more eggs than the Italians, but with 75 per cent. there was little difference between the breeds. Birds given 75 per cent. grain gained, the others lost weight; another group given only 30 per cent. grain did so badly that that part of the experiment had to be stopped after only a month. Least feed was consumed when 75 per cent. grain was given. In spite of the higher cost of the rations higher in grain, feed costs per 100 g. eggs plus meat fell as the percentage of grain rose; they were, respectively, 21·6, 19·7 and 17·5 Pf. Hence in an all-mash ration, the inclusion of 75 per cent. of grain is recommended.—W. M. Deans.

3955

MEHRING, A. L. (Jr.), TITUS, H. W. and BRUMBAUGH, J. H. **Effects of two sulfonamides on the formation of egg shells.** *Poultry Sci.*, 1955, **34,** 1385–1389. [Lime Crest Res. Lab., Limestone Products Corporation of America, Newton, N.J.]

Two unsubstituted sulphonamides, 2-acetylamino-1 : 3 : 4-thiadiazole-5-sulphonamide and benzenesulphonamide, given in capsule form to laying pullets, in amounts of 50 to 100 and 35 mg. daily, respectively, resulted in the production of thin-shelled eggs or eggs with no shell. Some of the pullets ceased laying. Normal eggs were laid soon after treatment ceased.—J. S. Thomson.

3956

CARTER, R. D., RISNER, R. N. and YACOWITZ, H. **Some effects of growth hormone preparations in pullets and mature hens.** *Poultry Sci.*, 1955, **34,** 1407–1414. [Ohio Agric. Exp. Stat., Wooster.]

Daily injection into pullets and hens of 1 or 2 mg. growth hormone from cattle for 25 days had little effect on growth or feed consumption but reduced egg production, the decrease continuing for 10 days after the injections ceased. Pullets injected with growth hormone from pigs showed a small growth response, but the effect on egg production was similar. Most of the pullets receiving the injections became broody, and the reasons for this are discussed.—J. S. Thomson.

3957

POPIEL, K. and SIKOROWICZ, Z. Wpływ zróżnicowanego odczynu pokarmu na kształtowanie się iolściowego stosunku obu płci u kury domowej. [**The effect of differential feeding of hens on the sex ratio.**] *Pamiętnik Inst. Zootech. Poland*, 1955 (1956), 61–73. Russian and English summaries.

The ratio of cockerels to pullets in the progeny of hens fed on an acid-producing diet and mated with cocks on an alkali-producing diet was 2·8 to 1. In the progeny of hens on alkaline diet and cocks on acid diet the ratio was 1 to 2·3. (From summary.)—J. S. Thomson.

OTHER BIRDS

3958

COULTER, M. W. **Spring food habits of surface-feeding ducks in Maine.** *J. Wildlife Management*, 1955, **19,** 263–267. [Maine Cooperative Wildlife Res. Unit, Orono.]

The stomach contents of 72 wild ducks caught in muskrat traps were examined. There were 39 wood ducks, 20 black ducks, 12 green-winged teal and one blue-winged teal. The vegetation of the area from which they were obtained is described. Most of the feed was obtained from the seeds of sedges (*Carex* spp.), rushes (*Scirpus* spp.) and bur-reed (*Sparganium* spp.). Where available some fruits of bushes were also eaten, more by the black ducks than the others, and the proportion of animal feed, insects, eaten was from 6 to 10 per cent. of the total feed intake. Pondweed was not encountered as much as expected, probably because seeds were unavailable because of covering by flooding and silting.—T. D. Bell.

3959

BAILEY, W. J. (Jr.), SHARP, W. M., HAZEL, R. B. and DAVIS, G. **Food habit trends of ruffed grouse in the Centre county "Barrens" (based on droppings analysis.)** *Pennsylvana Agric. Exp. Stat. Bull.* No. 604, October 1955, pp. 18.

The advantages of the method are discussed. The seasonal trends of food habits are indicated. Fruit of oak, wild grape and teaberry, and aspen buds and some green leaves were the most used

foods. The importance of these items varied from year to year, depending on the relative yields of the fruits. The seasonal trend showed fruits to be most important in the autumn, diminishing in volume eaten as winter came on. Consumption of buds increased as the fruits became unavailable. Droppings collected at different sites showed difference in the choices of the birds, thought to be due to the availability of specific feeds at particular places. One cause of the variation in availability was the use of the succulent fruits by deer and migratory song-birds. Frost-resistant leaves, including 2 families of ferns, were important sources of food during the winter, but aspen buds were dominant.—T. D. Bell.

3960

DALE, F. H. **The role of calcium in reproduction of the ring-necked pheasant.** *J. Wildlife Management*, 1955, **19,** 325–331. [U.S. Fish and Wildlife Serv., Laurel, Md.]

Field observations indicated that in 2 areas similar agriculturally, but one on calcareous and one on non-calcareous soil, the pheasant population in the former was normal, and in the latter very low.

Experiments with pens of 20 pheasants were made. Diets were similar, except that in half the pens the feeds came from the calcareous, and in the other half from the non-calcareous area. Both these diets were adequate for maintenance, but not for reproduction. It was thought that grit was of importance for reproduction, and limestone or granite grit was added to each of the rations.

Rations from both areas with limestone grit gave satisfactory reproduction. Granite grit and the ration from the chalk area were marginal, and granite grit and the ration from the other area were still unsatisfactory. A supply of Ca carbonate rapidly rectified the fault. It was concluded that lack of limestone in the non-calcareous area was the cause of the low pheasant population. Bone ash of the birds on the different rations did not differ significantly. In birds which did not lay properly, development of the ovaries was normal. The role of Ca in ovulation is discussed.

MICHAEL, V. C. and BECKWITH, S. L. **Quail preference for seed of farm crops.** *J. Wildlife Management*, 1955, **19,** 281–296. [Sch. Forestry, Univ. Florida, Gainesville.]

In 600 trials the preference of quail for 53 types of seeds was investigated. Grass seeds were preferred to legumes, and the consumption of the legume seeds increased only when the supply of grass seeds declined. Even when no other feed was offered for 7 days quail would not eat seeds which were known to be toxic. It was demonstrated that the quail had a highly developed sense of smell which enabled them to find the preferred seeds even when buried under seeds rating low on the preference list. The placing of the feeds in different positions did not affect the choice of the birds and they did not require any length of time to become accustomed to new seeds which they found palatable. Harvester ants showed the same feed preferences as quails, and would be a serious source of competition, but cotton rats preferred seeds not chosen by quail. A diet of only one to 3 different seeds, even of the most highly preferred, caused loss of weight, and signs of deficiency of vitamin A, which could be cured by giving a wide variety in the diet. On inadequate diets hens were twice as likely to die as cocks.

3962

BECK, J. R. and BECK, D. O. **A method for nutritional evaluation of wildlife foods.** *J. Wildlife Management*, 1955, **19,** 198–205. [Dept. Biol., Univ. Tennessee, Martin.]

A method for studying food habits of birds, which takes into account the amount eaten and the percentage of requirement of energy, protein and minerals it meets, is presented. It requires refinement to allow for vitamin requirements and trace minerals, but would be a useful guide to gamekeepers concerned with maintaining wild game.—T. D. Bell.

FOOD ECONOMICS AND STATISTICS

3963

FOX, K. A. and TAEUBER, R. C. **Spatial equilibrium models of the livestock-feed economy.** *Amer. Econ. Rev.*, 1955, **45,** 584–608. [Div. Agric. Econ., U.S. Dept. Agric.]

The spatial equilibrium model considered in this paper attempts to determine the level of production and consumption of both livestock and cattle feed in each of 10 regions in the United States and the aggregate amount and direction of inter-regional trade in these 2 commodities. The main difference between this model of jointly dependent commodities and those, quoted by the authors, which deal with single commodities is similar to the difference between the simultaneous equations and the single equation approach in econometrics. Spatial equilibrium is held to exist when (a) demand and supply are equal in the U.S. as a whole (gross equilibrium)

and (b) trade between regions of excess and deficit is determined in such a way that no trader could obtain more profit by further shipments.

The model consists of 42 equations, 40 determining the production and consumption of feed and livestock in each region and 2 specifying the gross equilibrium requirements for livestock and cattle feed separately. The production and consumption equations are jointly dependent, *i.e.*, some of the determining variables in one equation will be the dependent variables in others. A gross equilibrium position, in which prices, production and consumption within each region are consistent with the equations of the model, is obtained by a repeated trial and error process. The regional production and consumption levels at this gross equilibrium position determine the aggregate amount of inter-regional trade. The direction of trade is apparently determined by a linear-programming method similar to that used in the transportation problem by Koopmans.

The authors claim that the model could be used in a system of competitive markets with continuously varying prices to determine, *e.g.*, an equilibrium price structure, an allocation of trade or a transportation charges structure which will maximise or minimise a particular linear function, *e.g.*, profits or transportation costs. It could also be used to discover the effect of a change external to the model. Examples are given of the effects of a drought in part of the U.S. and of an increase in freight rates for feed. The main difficulty encountered in applying the model, the authors declare, is the inability to obtain satisfactory demand and supply functions.—P. Fisk.

DUTHIE, W. B. **Economics of hill farming. Blackface or Cheviot? An economic comparison between Blackface and South Country Cheviot breeds of sheep in the Border Counties, 1946 to 1953.** *Edinburgh and East of Scotland Coll. Agric. Tech. Bull.* No. 14, June 1955, pp. 20.

In an 8-year economic study of 50 Border hill farms, 25 carrying South Country Cheviots and 25 carrying Blackfaces, Cheviots required 0·4 acre rough grazing less per ewe and as draft ewes made higher prices than Blackfaces. The average lambing percentage of Blackfaces was 82·0 and that of Cheviots 80·4. Fleeces of Blackfaces were superior in weight, 4·4 lb. as against 3·9 lb., but inferior in value, 13s. each as against 14s. 4d. Blackface store lambs were slightly dearer than Cheviot store lambs, but hypothetical income from flocks of 1000 ewes slightly favoured the Cheviot. Mortality of Blackfaces was 4·6 per cent. of total stock at marking time and of Cheviots 4·8 per cent. The change-over of some hill farmers from South Country Cheviot sheep to Blackface sheep is discussed.—J. C. Gill.

BERKOWITSCH, J. Kraftfutterindustrie in Venezuela. [**Concentrate industry in Venezuela.**] *Schweiz. Landwirtsch. Monatsh.*, 1956, No. 1, Sonderheft 60. Geburtstag. Prof. Crasemann, 57–66. [Protinal C.A., Valencia, Venezuela.]

This article gives an idea of the rapid growth of the feedingstuffs industry in Venezuela. Large-scale manufacture began only in 1942 and the amount of compound feedingstuffs produced has risen from under 350,000 kg. in 1943 to over 59 million kg. in 1954, of which 57 million kg. were accounted for about equally by poultry and dairy cows. Horse feed amounted to 817,000 kg. and pig feed to 571,000 kg. The main local raw materials are maize and maize offals, rice offals, molasses, cocoanut, sesame, cottonseed, and sardine meal; dried skimmed milk, phosphates, vitamins and antibiotics are imported. Owing to the absence of some common ingredients and the abundance of others, some of the mixtures produced are quite unorthodox. Before sale they must be registered with the Ministry of Agriculture with particulars of ingredients and minimum content of crude protein, crude fat and N-free extractives and maximum content of crude fibre; and sacks must be labelled with particulars of ingredients and nutrient content.—W. M. Deans.

REBER, E. F. and YUSKEN, J. W. **The effect of a high level of dietary sodium on the nutrition of baby pigs infected with transmissible gastro-enteritis.** *N. Amer. Vet.*, 1956, **37,** 198–201. [Dept. Vet. Physiol. Pharmacol., Univ. Illinois, Urbana.]

Seven littermate pigs were selected and divided at 7 days of age on an equal weight basis into groups of 3 and 4. At 20 days of age the group of 3 was infected with transmissible gastro-enteritis. The 2 groups were given the same semi-synthetic ration, which contained 920 mg. Na and 1020 mg. K per 100 g. ration, and each group was tended by different people. Faeces, urine and vomitus were collected for estimation of N, Na and K. Faecal excretion of N, Na and K was greater in the infected pigs, but no negative balance was found; in previous experiments when dietary Na was low K balance became negative (Reber and Whitehair, *Amer. J. Vet. Res.*, 1955, **16,** 116). The high dietary level of Na seemed to counteract to some extent the disturbance of K metabolism due to the infection.—T. D. Bell.

3977

LUDVIGSEN, J. Undersøgelser over den såkaldte "muskeldegeneration" hos svin. 4. Studier over pathogenesen. [**Studies of so-called "muscle degeneration" in pigs. 4. Pathogenesis.**] *Forsøgslab. København Beretn.*, 1955, No. 284, pp. 84. English summary.

For earlier reports see Absts. 1497 and 5983, Vol. 25.

4. The *p*H of degenerated muscle at slaughter is always below that of normal muscle, 5·3 to 5·5, and normal 6·4 to 6·7. It is suggested that disturbance of intermediary metabolism of carbohydrate is responsible: glycogen and pyruvic acid are low and lactic acid is high in abnormal

muscle, but pH is not closely related to the level of lactic acid. This implies a defect in buffering action which is attributed to lack of the normal amount of myoglobin. A comparison is made with Carlström's findings in myoglobinuria of horses (see Abst. 2898, Vol. 1). The amount of deposit carbohydrate at slaughter appears to determine the appearance of the abnormality in genetically predisposed pigs and restriction of feed for 24 hr. prevents it. There are differences between muscles by function and colour. Genetically predisposed pigs with muscular degeneration stored relatively more N and put on more flesh than normal pigs. Hormones are discussed again. The last section discusses rigor mortis in relation to quality of pork. It is important that pigs be rested before slaughter.—I. Leitch.

PARRY, H. B. **Prevention of toxaemia of late pregnancy in sheep.** *Nature*, 1956, **177,** 288–289. [Nuffield Inst. Med. Res., Woodstock Rd., Oxford.]

Data on the occurrence of pregnancy toxaemia in some 50 lowland flocks in England and Scotland are shown for 3 consecutive years. A striking reduction in the number of cases and in the number of deaths resulted from restricting gain of weight during early pregnancy and giving hay and concentrates to ensure good gains during the last 6 to 8 weeks. Over this period a concentrate feed of 10 per cent. good quality protein, at first at the rate of $\frac{1}{4}$ lb. per head daily and increased to 2 lb. during the last fortnight before lambing, is recommended. Severe weather might necessitate higher feeding levels. Exercise is also advisable.

J. C. Gill.

LEBEDEV, P. T. Usilnit raboty po diagnostike mineralnoi i vitaminnoi nedostatochnosti. [**Reasons why efforts to diagnose mineral and vitamin deficiency should be increased.**] *Veterinariya*, 1955, **32,** No. 10, 81–83. [Sibirsk. Nauch.-Issled. Vet. Inst.]

The need to control intakes of Ca, P and carotene, especially in pregnant cows, is illustrated with examples from collective farms. An association between gastric disorders, lung illnesses and vitamin and mineral deficiency has been proved by many experiments. If in the last third of pregnancy the mother's diet is supplemented with 15 to 25 g. Ca, 10 to 18 g. P and 90 to 120 mg. carotene per 100 kg. bodyweight better offspring with a higher resistance to disease will result. Examples of how improvement of diet increased the survival rate of calves, diminished the incidence of gastric and other disorders and improved the milking capacity of cows are quoted. Blood analysis is advocated as a method of determining whether action should be taken, though pregnant animals should receive supplements in any case.

BARNES, J. E. and JEPHCOTT, B. R. **Phosphorus deficiency in cattle in the Northern Territory and its control.** *Austral. Vet. J.*, 1955, **31,** 302–312 (with discussion 312–316). [Animal Indust. Branch, Northern Territory Admin., Alice Springs.]

The condition known as "peg-leg" was widespread in the Northern Territory in 1952 and in 1954, during droughts. Affected cattle were poorly developed, with fine bones liable to fracture, poor in condition, with dull, rough coats and sometimes depigmentation, patchy alopecia and kyphosis. Lameness, sometimes acute, was common, especially in lactating cows. There was no correlation in 137 cattle between the incidence of the disorder and Hb value. Post-mortem examination showed erosion of articular cartilages, especially at the elbow and hock; osteomalacia was common. Tendon sheaths of the flexor tendons of the metacarpal and metatarsal regions were often inflamed.

Peg-leg was significantly correlated with low serum inorganic P; the values obtained might have been lower still if the animals had not been driven and thrown before samples were taken. Serum Ca was high whether or not the cattle had peg-leg. It is concluded that the condition is due to deficiency of P.

Soils from affected areas in the Barkly Tableland region had low or very low total P, nearly always below 0·05 per cent. P_2O_5. A limited number of pasture samples had a mean P content of 0·07 per cent. Water samples contained no P. The provision of bonemeal in troughs is not considered to be a satisfactory solution to the problem under the conditions of cattle production; addition of sodium orthophosphate to the drinking water is suggested, and a cheap and effective method is described.—D. Duncan.

3984

STEWART, J. and REITH, J. W. S. **The effects of magnesium liming on the magnesium content of pasture and the blood level of magnesium in cows.** *J. Comp. Pathol.*, 1956, **66**, 1–9. [Moredun Inst., Gilmerton, Edinburgh.]

Trials were made on a farm where tetany with low blood Mg was prevalent. The Mg content of herbage from pasture plots given a single dressing of 40 cwt. ground limestone (48 per cent. CaO, 2 per cent. MgO) per acre was similar to that from plots where no lime was applied. The annual mean Mg content was from 0·20 to 0·25 per cent. in the dry matter during 3 years. A single application of 40 cwt. ground magnesium limestone (31 per cent. CaO, 20 per cent. MgO) per acre raised the Mg content to 0·31 to 0·38 per cent. in the dry matter over the same period. Seasonal variations were apparent in all herbages, lowest values occurring in April and May. Blood serum Mg values of grazing cows were lowest in these months. Pastures treated with magnesian limestone were grazed continuously by a total of 12 cows during 4 consecutive years. In April of the year of application the mean Mg content of the serum was 1·78 mg. per 100 ml.; corresponding values in the subsequent 3 years were from 2·09 to 2·22, and for 6 cows grazing pastures of similar type not treated with magnesian limestone they were from 1·74 to 1·85 mg. during the 4 years. It is concluded that magnesian limestone dressings considerably improved the level of blood Mg in cows on this farm.—J. L. Corbett.

3985

WYNNE, K. N. and MCCLYMONT, G. L. **Copper-molybdenum-sulphate interaction in induction of ovine hypercupraemia and hypocuprosis.** *Austral. J. Agric. Res.*, 1956, **7**, 45–56. [Nutrit. Res. Lab., Vet. Res. Stat., Glenfield, N.S.W.]

Merino sheep in 5 groups of 6 or 7, with some black sheep in each group, received a basal diet of chaffed wheaten or oat hay, oats, wheat and meat-meal, containing Cu 5·2 p.p.m., Mo 0·83 p.p.m. and inorganic sulphate 0·04 per cent. One group received a supplement of ammonium molybdate to raise the Mo content to 5·14 p.p.m., one group sodium sulphate to raise the sulphate to 0·40 per cent., one group had both these supplements and another group had the ration with both supplements but with feed intake restricted to 2·7 kg. weekly given in only 2 feeds. The controls had no supplement. Liver biopsy samples were taken at intervals and blood was analysed for Cu on 3 occasions.

Sheep on the basal diet maintained liver Cu concentrations with relatively little change for 30 weeks and had normal blood Cu and wool. Sheep given both supplements showed a progressive fall in liver Cu, from 222 p.p.m. initially to 12·8 after 50 weeks; blood Cu fell to 0·042 mg. per 100 ml. after 43 weeks and the wool of the black sheep showed light bands. In the group on restricted feeding the fall in liver Cu was similar and so were the wool changes, but the fall in blood Cu was later in appearing. With no Mo supplement alone, liver Cu fell less, from 306 to 170 p.p.m. in 30 weeks, blood Cu remained within low normal limits and the wool showed no change. With sulphate alone, liver Cu fell in 50 weeks to 49·8 p.p.m., blood Cu fell slightly and the wool was unaffected.

It is concluded that the signs of Cu deficiency in sheep in New South Wales can be explained as an effect of the interaction of Cu, Mo and sulphate.

D. Duncan.

3986

ANDERSON, J. P. and ANDREWS, E. D. **The effect of phenothiazine on cobalt-deficient and cobalt-dosed lambs.** *N.Z. Vet. J.*, 1955, **3**, 150–151. [Dept. Agric., Invercargill.]

Of 4 groups of 10 lambs on a cobalt-deficient paddock one group was given 20 g. phenothiazine per lamb per fortnight, another 7 mg. cobalt per lamb per week, a third 20 g. phenothiazine per lamb per fortnight and 7 mg. cobalt per lamb per week and a fourth group acted as control. Compared with the controls, mean weight gains were higher and death rate lower in lambs given phenothiazine, but neither difference was significant. No significant difference was found between mean weight gains of lambs given cobalt and of those given cobalt and phenothiazine, but in both, weight gains were over twice those of controls.

3987

CUMMING, R. B. and TRIBE, D. E. **The effect of floor type and the choline content of the diet upon the incidence of perosis in chickens.** *J.*

Agric. Sci., 1956, **47**, 103–106. [Sch. Vet. Sci., Univ. Bristol.]

The occurrence of perosis is reported in chickens on the vitamin-E-deficient diet No. 124 of Dam *et al.* (Abst. 3372, Vol. 21). Dam had reported the occurrence of encephalomalacia, but not perosis.

Four experiments are reported with the diets of Dam *et al.* containing 55 p.p.m. Mn and 500 mg. choline per kg., with 340 Rhode Island Red × Light Sussex day-old cockerels. In chickens brooded on a wooden floor the incidence of perosis was 42 per cent.; in those brooded on wire floors, 78 per cent. The addition of Mn up to a level of 1100 p.p.m. had no effect on the incidence, nor had doubling the floor space. When the choline content was raised to over 800 mg. per kg. the incidence was reduced to 15 per cent., but still higher additions, up to 1400 mg. per kg., did not further reduce it. Bodyweight at 21 days increased with increasing choline content of the diet up to a level of 1400 mg. per kg., and it is concluded that this is the least requirement for maximum growth.—J. S. Thomson.

3988

JOYCE, J. M. **Posterior paralysis in pigs. Summary of a Northland survey, 1954.** *N.Z. Vet. J.*, 1955, **3**, 157–158. [Te Hana.]

A survey of the incidence, signs and treatment of posterior paralysis in pigs indicated that the disease might be due to a deficiency of either copper or vitamin A. In areas of Cu deficiency with livers showing a Cu content of from 6 to 12 p.p.m., copper sulphate improved the condition. In other areas without deficiency of Cu, fish liver oil either alone or with copper sulphate or yeast had a beneficial effect.—J. S. Thomson.

DISEASES OF METABOLISM

3989

BEIJERS, J. A. **Vetverharding of vetnecrose. [Fatty induration or fatty necrosis.]** *Tijdschr. Diergeneesk.*, 1956, **81**, 199–207. [Klin. Inw. Ziekten, Diergeneesk. Fac.] English, French and German summaries.

This disorder is more common in young than in mature animals, especially in calves. Fatty tumours are palpable superficially and occur in the omentum, and mesentery along the stomach, colon and rectum. Clinical signs are of digestive disorders, colic and loss of weight and are not diagnostic; of laboratory analyses only a low blood cholesterol has been found consistently, and histologically defects in the islets of Langerhans. Etiology is obscure.—I. Leitch.

3990

'T HART, M. L. and KEMP, A. De invloed van de weersomstandigheden op het optreden van kopziekte bij rundvee. **[Effect of weather on the occurrence of grass tetany in cattle.]** *Tijdschr. Diergeneesk.*, 1956, **81**, 84–95. [Centraal Inst. Landbouwk. Onderzoek, Wageningen.] English, French and German summaries.

The incidence of grass tetany was recorded for about 750 farms in the Netherlands for 11 years, during which time there were 1146 cases. A study of variations in environmental temperature in relation to the incidence of grass tetany was made. There was a peak in spring, and 940 of the cases occurred in the first half of the year. Nearly all of them occurred between the time when the cows went out to grass and the time when the mean temperature for 10 days rose above 14° C., and in autumn the incidence increased when the mean temperature fell below that level, especially in wet years. When there was a sharp rise in temperature in spring it was commonly followed, on the average 5·1 days later, by a rise in the incidence of grass tetany, and a sharp drop in temperature was followed by a fall in the number of cases, also 5·1 days later. In spring the number of cases was directly proportional to the rate at which the grass grew.—D. Duncan.

3991

SJOLLEMA, B., VAN KOETSVELD, E. E., GRASHUIS, J. and LEHR, J. J. Onderzoekingen over kopziekte 2. **[Grass tetany 2.]** *Tijdschr. Diergeneesk.*, 1955, **80**, 1111–1134. [Inst. Moderne Veevoeding " De Schothorst ", Hoogland.] English, French and German summaries.

For part 1 see Abst. 1343, Vol. 26.

2. The same 8 cows as were used in the spring experiment were studied in autumn. The 3 which had no attack of tetany in spring were given K salts, 3 which had had tetany now received Na salts, and the other 2 received Mg. Serum composition was studied for 3 months.

Serum Mg fell in all the cows except those given Mg. One of the cows given Na salts had an attack of grass tetany early in October, and another in this group had oedema of the lung followed by emphysema. The cows of this group had a high intake of K as well as of Na. Serum inorganic P was high, 6·8 to 11·2 mg. per 100 ml., in the cows given K salts, but not in those given Na. The results agree with those of the spring experiment.—D. Duncan.

ADLER, J. H. and DYE, J. A. **On the mechanism of ketogenesis in ruminants.** *Cornell Vet.*, 1956, **46**, 58–63. [Dept. Physiol., New York State Vet. Coll., Ithaca.]

The demands of pregnancy, especially in high producing cows and multiparous ewes, and the peculiarities of energy metabolism in the ruminant, in which most of the carbohydrate is absorbed as ketogenic fatty acids, are considered to be concerned in the etiology of ketosis.

T. R. Preston.

3993

HOPKINS, D. W. **Ketosis from the feed manufacturer's standpoint.** *N. Amer. Vet.*, 1956, **37**, 22–28. [Greenfield, N.H.]

In a discussion of ketosis in dairy cattle in relation to feeding practices, data from 5 herds are quoted which indicate that the incidence of the disease is higher where feeding programmes are such that cows calve in over-fat condition and are then often fed on production rations low in protein. It is suggested that feeding in-calf cows on rations with a narrow nutritive ratio, so that they would lay down flesh instead of fat, might reduce the incidence of ketosis.—T. R. Preston.

3994

KROOK, L. and ARWEDSSON, G. **On urolithiasis in the dog.** *Nord. Vet.-Med.*, 1956, **8**, 65–72. [Dept. Pathol., Royal Vet. Coll., Stockholm.] German and Swedish summaries.

Analysis of 245 records of urinary calculi in dogs showed that there was in the affected dogs a highly significant excess of Dachshunds and a significant excess of Pekinese and Poodles with a significant deficit of Airedale terriers, Alsatians and Boxers. That is to say, dogs of breeds characterised by chondrodystrophy showed an excess. The disease becomes more frequent with age ; sex has no effect ; surgical treatment is palliative only. Urolithiasis in dogs appears, therefore, to be a disease of metabolism, specifically of Ca and P metabolism, associated with breed.—I. Leitch.

3998

TUGWELL, R. L. **Helminth infections in relation to restricted feeding on range.** *Poultry Sci.*, 1955, **34**, 1372–1375. [Poultry Dept., Univ. Tennessee, Agric. Exp. Stat., Knoxville.]

A survey was made of the helminth burden of poultry over 4 years. Four groups of birds were given different amounts of mash. All the birds were put on pasture when they were 12 weeks old and housed in mid-September when they were 24 weeks old. There was a gradual build up of helminths throughout the period of observation. Birds on restricted amounts of mash tended to have more helminths than those fed to appetite. The number of helminths collected continued to increase after the birds had been housed.

7. BOOK REVIEWS

3999

PAECH, K. and TRACEY, M. V. (Eds.) Moderne Methoden der Pflanzenanalyse. Erster Band. Vierter Band. [**Modern methods of plant analysis. Volumes 1 and 4.**] Springer-Verlag, Berlin, 1956, pp. xvii + 542. Price 151s. 6d. ; 1955, pp. xiv + 766. Price 203s.

Volumes 2 and 3 of this work have been reviewed earlier (Abst. 6005, Vol. 25).

Volume 1 deals with general considerations relating to plant material, general methods for separation, making and handling extracts, electrical transport, counter-current distribution, chromatography on columns and paper, colorimetric, absorptiometric and fluorimetric methods, refractometry and interferometry, polarimetry, nephelometry, principles of biological assay, methods involving labelled atoms, estimation of *p*H values in living tissues and saps, oxidation-reduction potentials, gasometric analysis in plant investigations (Warburg, Van Slyke, microdiffusion methods and the estimation of ethylene), cytochemical methods, mineral components and ash analysis. A few of the sections deal specifically with plant materials, but most are general and the volume as a whole will serve most biochemists, not only those interested in plant biochemistry. Several similar publications have appeared in recent years ;

nevertheless, these articles are of considerable interest and are noteworthy for the detail with which both theory and practice are considered. Any student or research worker using the techniques discussed here for the first time would profit by reading the appropriate section of this book in order to appreciate fully the theoretical bases and the possibilities and limitations of the methods. As in the later volumes of this work, each section includes an extensive bibliography.

Volume 4 deals with analytical methods applicable to peptides and free amino acids, proteins (including their nutritive value), urea and ureides, chlorophylls, haematin compounds, adenosine di- and triphosphate, coenzymes I and II, nucleic acids and related compounds, vitamin B_1 and its derivatives, alkaloids, amines and betaines, pantothenic acid and coenzyme A, riboflavin, folic acid and biotin, melanins, compounds of hydrocyanic acid, mustard and leek oils and other sulphur-containing plant constituents. As before the treatment is detailed, authoritative and critical. The editors and contributors are to be congratulated on producing a work which will be of great value to biochemists both as a practical manual and as a work of reference.—H. G. Bray.

McDONALD, H. J. (with LAPPE, R. J., MARBACH, E. P., SPITZER, R. H. and URBIN, M. C.) **Ionography. Electrophoresis in stabilized media.** The Year Book Publishers, Inc., Chicago, Ill., 1955, pp. x + 268. Price 48s.

This book is a welcome addition to the literature on modern experimental techniques. Ionography is treated as an independent technique rather than as a modification of paper chromatography or traditional electrophoresis. The authors are clearly enthusiastic and expert technicians and have written a most readable account of their subject. About one-half of the book deals with fundamental considerations, *e.g.*, historical background, types of apparatus, nomenclature, general methods and procedures, mobility, and the relation between mobilities in stabilised and non-stabilised media. The remainder is concerned with the application of the technique to proteins, peptides, amino acids, carbohydrates and related compounds, lipoproteins and related substances, enzymes, hormones, vitamins and inorganic substances. A final chapter deals with miscellaneous applications of ionography, *e.g.*, ion transfer, electro-osmosis. The bibliography contains 760 references.

HALDEN, W., WENGER, R. and HARTL, H. Milch und Milchprodukte in der Ernährung und Diätetik. [**Milk and milk products in nutrition and dietetics.**] Gesundheitskommission der Österreichischen Liga für die Vereinten Nationen, Vienna, 1955, pp. iii + 60. Price 12 Sch.

An attractive brochure on milk and milk products, intended for doctors, nurses, dietitians and the intelligent layman. It is clearly printed and illustrated with 8 half-tone plates. There is no index but marginal headings make reference easy.

A brief preface by Professor Lauda (1. Med. Klin., Univ. Vienna) is followed by 3 independent chapters. In 12 pages Professor Halden (Graz) gives a concise account, with tables and select references, of the composition of whole milk and the role of the different constituents, including minerals and vitamins, in human nutrition. The next 10 pages briefly describe the composition and properties of skimmed milk, sour milk (including acidophilus milk, yoghourt and kephir), cream, butter, curds, cheeses, whey, condensed milk and dried milk.

Dr. Wenger (Vienna) follows with about 20 pages on the uses of milk, ordinary or modified, and milk products for pregnant and lactating women and old people and in hospital and other special diets for digestive disorders, liver diseases, diabetes, obesity and a variety of other diseases, with a caveat that for some patients the salt content may be too high.

The concluding chapter by Hartl deals with the collection and heat treatment of milk and the

manufacture of butter, curds, cheese, condensed milk and dried milk, and includes some statistics for Austria. In 1955 there were over a million dairy cows, and over a million and a half people (22 per cent. of the population) were engaged in agriculture. In 1954, 2539 thousand metric tons of milk were produced, valued at 4000 million Schilling, more than 20 times the value of Austria's coal production. Of this, 1361 thousand tons were used on the farms or sold direct to the consumer; of the 1178 thousand tons sent to the dairies, 571 thousand tons were sold as liquid milk, and the rest yielded butter 23,000, curds 6300 and cheese 14,600 tons. According to O.E.E.C., Austria comes seventh in Europe for milk consumption with 176 kg. per head per year, being surpassed only by Norway, Switzerland, Sweden, Holland, Canada and Éire.—W. M. Deans.

4007

SCHWIMMER, M. and SCHWIMMER, D. **The role of algae and plankton in medicine.** Grune and Stratton, New York ; London, 1955, pp. x + 85. Price $3.75.

This monograph on medical, including nutritional, uses of algae and plankton has a 15-page bibliography with over 300 references to newspapers, magazines, books, and scientific papers in a wide variety of journals, mostly non-medical. Of the text, rather less than half is devoted to seaweeds, a few pages to zooplankton and the remainder to phytoplankton, which consists mainly of microscopic algae.

The first part of the chapter on seaweeds deals with their composition and uses as food for man and beast. The second touches on past uses of seaweeds in the treatment of diseases, including deficiency diseases ; but nowadays emphasis has shifted to derivatives such as agar and alginates and a fuller account is given of the uses of these in medical treatment and medical research.

The brief section on zooplankton refers only to its use as food, and owing to the scarcity of supplies this is of interest chiefly to the victims of shipwreck. Phytoplankton has greater potentialities for human food, since cultivation is possible, though not yet on a practical scale, and an account is given of the nutrients supplied by and required by *Chlorella* and some other microscopic algae. The section on medical aspects, in addition to the unpleasant effects which algae may produce in reservoirs and sewage disposal plants, devotes a good deal of space to the poisoning of animals, and of man through the eating of certain fish. In the concluding discussion there are some interesting speculations about the possible role of algae in hitherto obscure diseases of the nervous system.

WISHART, J. and SANDERS, H. G. **Principles and practice of field experimentation.** Commonwealth Bur. Plant Breeding and Genetics, Tech. Commun. No. 18, 2nd ed., 1955, pp. vii + 133. Price 21s. (Obtainable from Commonwealth Agric. Bur., Farnham Royal, Slough, Bucks.]

This book, as its title implies, is directed principally at the experimenter in the field, who measures yields of crops. For the biological worker measuring growth and associated responses a certain amount of adaptation is necessary. This is particularly true of the second part of the book, dealing with practical considerations.

The opening chapters illustrate a uniformity trial, the methods of calculation adopted, and the principles underlying tests of comparison between 2 or more samples.

The subsequent chapters of the first part deal with different problems and the designs of increasing complexity, along with the appropriate methods of analysis, for handling these problems. The points raised are well illustrated. This part of the book closes with a chapter on the subject of sampling, and one on the analysis of covariance, which is clearly illustrated for the case with one concomitant observation.

The second part of the book is written for the agricultural worker, who, armed with the statistical principles laid out in the first part, is preparing to make his experiments. Perhaps the most valuable chapter is that dealing with policy and general procedure (Chapter 12), which offers much practical wisdom. Of this, the advice to decide on the questions which are to be answered, and to " spend time in reconnaissance ", can never be repeated too often. Another chapter deals with the importance to agriculture of differences which are shown to be statistically significant. The remainder of the book deals with the shape and size of plots and their lay-out, and with the methods of sampling from them. The final chapter is another which cannot be read too often. It discusses the day-to-day management of an experiment and the need for keeping an accurate record of all the methods of treatment and sampling used, in fact, a diary containing all the information likely to have any bearing on the results.

In summary, this book presents much useful advice on the conduct and interpretation of experiments, with emphasis on crops and field trials. The only quarrel which the reviewer has with it is on account of the advice to apply t-tests to individual comparisons in an experiment where several treatments are being tested, as this tends to exaggerate the significance of differences.

A. W. Boyne.

4009

ROWETT RESEARCH INSTITUTE, BUCKSBURN, ABERDEENSHIRE, SCOTLAND. **Collected papers, Volume 12, 1956.**

This volume contains 72 papers, some by title only, published during the year 1955, with an introductory summary by the Director of the year's work and two reviews, one covering the past 6 years' work at the Institute on "Micro-organisms concerned in the fermentation of non-cellulosic carbohydrates in the rumen" by A. E. Oxford and the other on "Pig research at the Institute, 1948–1955" by I. A. M. Lucas.

The bound volumes of papers are available only to a small and selected number of those interested but copies of the summary and progress reports are available on application to the Librarian.

8. SYMPOSIA, PROCEEDINGS AND CONGRESS REPORTS

Proceedings of the Second Radioisotope Conference, Oxford, July 1954, Johnston, J. E. (Ed.). Butterworths Scientific Publications, London.

Medical and Physiological Applications, Vol. 1, pp. 418; Vol. 2, pp. 223.

The conference, attended by 800 delegates from over 30 countries, was sponsored by the Atomic Energy Research Establishment, Harwell. There were 70 papers in all, in sessions on therapy, diagnosis, animal physiology and pathology (2), biochemistry (3) and plant nutrition, reported in Vol. 1, and on chemistry, chemistry and metallurgy, physics and industrial applications, and industrial applications, reported in Vol. 2 all fully, with the discussions.

Diagnosis, LEDLIE, E. and BAXTER, C. F. (97–106), clinical applications of tracer doses of ^{59}Fe.

Animal Physiology and Pathology, LACROIX, P. (134–137), study of bone metabolism with radio-active Ca and S (dog); MILLER, H., MUNRO, D. S., RENSCHLER, H. E. and WILSON, G. M. (138–146), measurement and distribution of exchangeable sodium (man); REED, G. W. and CARE, A. D. (147–160), migration of ^{24}Na, ^{38}Cl and ^{42}K across bladder and intestinal mucosa (man); HAMILTON, J. G., WALLACE-DURBIN, P. and PARROTT, M. W. (219–231), acute and chronic changes produced by iodine-131 and astatine-211 at lethal levels (rat), and uptake of astatine-211 in patients with thyroid disease; FORSSBERG, A. and KLEIN, G. (232–242), effects of X-rays on incorporation of glycine-2-^{14}C into Ehrlich ascites tumour (mouse).

Biochemistry, PICHAT, L., BARET, C., AUDINOT, M., HERBERT, M. and LAMBIN, J. (245–257), synthesis of ^{14}C-labelled compounds, including glutamic acid and proline; CATCH, J. R. (258–261), carbon-14 amino acids from *Chlorella*; GLASCOCK, R. F. and REINIUS, L. R. (262–270), synthesis of tritium compounds with high specific activity and their use in biochemical research, *e.g.*, on stearic acid metabolism during lactation (goat); CRITCHLOW, A. and GOLDFINCH, M. K. (271–280), preparation of thyroxine labelled with ^{131}I and its use as an analytical tool; WOLF, G., JOHNSON, B. C. and KAHN, S. G. (283–286), synthesis of vitamin A-2-^{14}C; ROSENBLUM, C., WOODBURY, D. T. and REISNER, E. H. (Jr.) (287–297), evaluation of intrinsic factor activity with cobalt-60 labelled vitamin B_{12} (man, rat); FRAZER, A. C., POVER, W. F. R. and SAMMONS, H. G. (298–305), rate of elimination of ^{14}C labelled organic compounds, *e.g.*, distearyl tartrate, effect of fat intake (rat); SCHAMBYE, P. and WOOD, H. G. (346–350), conversion of ^{14}C-glycerol into liver glycogen *in vivo* (rat).

Industrial Applications, BROWNELL, L. E. and NEHEMIAS, J. V. (213–221), studies with a gamma radiation source of high intensity, on exposure of canned foods, fresh or raw frozen, pork and other meat, cereals and potatoes.

Symposium on nutritive aspects of preserved food. Proceedings. Göteborg, Sweden, October 1954.

SIK-Publication 115. Swedish Inst. Food Preservation Research (SIK). Göteborg, 1956. 30 Swedish crowns (incl. postage). 173 pp. mimeographed.

The symposium was organised under the auspices of the Comité International Permanent de la Conserve (CIPC).

The introductory analysis by BORGSTRÖM, G. (11–23) discusses general trends in food processing with some less familiar points: the craze for low-calorie diets with the associated danger that carboxymethyl-cellulose compounds may act as ion exchangers in the gastro-intestinal tract; the dangers to human health of the use of antibiotics in veterinary medicine and to the health of animals fed on the offal of other animals treated with hormones during fattening; the danger of rancid fat and, still greater, of highly dispersed, oxidised fat; GORTNER, R. A. (Jr.) (24–34) reviews recent progress in the field of nutrition, with the sole novelty that lipoic acid may be a component of the vitamin B complex; LANG, K. (35–40) discusses the necessity for the use of conserved foods; ADAM, W. B. (41–60) reports that the minimum loss of vitamins attainable in canning fruits and vegetables is now very small; MELLANDER, O. (61–65) shows that the amino acid composition of a protein is not necessarily a reliable guide to its biological value; the peptides which result from hydrolysis are decisive; human and cow's milk are compared; ÅGREN, G. (66–78) describes an automatic apparatus for sampling and titrating hydrolysates of protein in microbiological work, reports amino acids in a number of plant foods and discusses limiting amino acids; methionine is most frequently limiting in Swedish foods. Unpublished estimates of amino acids in human foetal and adult liver and muscle are presented to show that the greatest demand is possibly for *iso*leucine, leucine, threonine, tryptophan and valine, none of which appears as a limiting amino acid in rat experiments. CREMER, H. D. (79–84) deals with the effect of heat on protein with special reference to milk protein and DÜRRENMATT, K. (95–107) with dehydrated milks and the digestibility of different types. In the discussion on these papers, VAHLQUIST

announced an experiment running in north Sweden to study the immunological reactions and biochemistry of infants fed on breast milk, fresh cow's milk and dried milk. Other papers were by ALM, F. (108–111) on the decomposition of protein in semi-preserved herring (pickled, spiced and sometimes preserved with benzoic acid); GEIGER, E. (112–114), on histamine in poisoning by fish; CHARLEY, V. L. S. (115–125), on fruit juices; NIELSEN, N. (126–132), on vitamin B_{12} in processed foods and its effect on undernourished subjects; DAHL, O. (133–137), on loss of weight in canning beef as affected by pretreatment; SÖDERHJELM, L. (138–143), on essential fatty acids in human nutrition. There was a discussion on the nutritional effects of rancid fat and polymerised oils followed by papers by ECKERSTRÖM, S. (151–158), on problems of old age; CLIFCORN, L. C., on dietetic canned food; ABDON, N., on canned food for babies; FRAZER, C. A. (159–170), on control of chemical aids in processing and finally, DELPHIN, K. A. (171–173), on preserved food in military establishments.

Commission d'Études du Centre National de Coordination des Études et Recherches sur la Nutrition et l'Alimentation. **[Committee on Studies of the National Centre for the Coordination of Study and Research on Nutrition and Diet.]** *Ann. Nutrit. Alimentation*, 1955, **9**, 271–309.

A discussion on digestion in ruminants with an introduction by E. F. TERROINE. The first section deals with the composition of foods, with contributions from JARRIGE (280–283) on carbohydrate; FAUCONNEAU (283–286) on nitrogen; FRANÇOIS (286–288) on lipids and pigments and also on mineral matter.

The second section deals with the physiology of digestion, with contributions from DUSSARDIER (289–291) on the origin of extrinsic gastric contractions; BRUNAUD (291–294) on cannula for permanent fistula of the digestive tract, physiology of the rumen, composition of the stomach muscle, pharmacodynamic studies, physiopathological role of histamine; LE BARS (294–297) on humoral intervention in motility, effect of different foods on motility and origin of typanites.

Section three dealt with the microbiology of digestion with a contribution by POCHON (298) on bacterial flora under different dietary regimes.

The fourth section was on the biochemistry of digestion with contributions from FRANÇOIS and ZELTER (299–300) on digestion of carbohydrates; RERAT (300–304) on utilisation of urea, RAYNAUD (304–306) on variations in the total nitrogen content of various parts of the digestive tract; RERAT (306–309) on synthesis of vitamins in the digestive tract.

Verhandlungen der Vierten Konferenz der Internationalen Gesellschaft für Biologische Rhythmus-Forschung, Basle, September 1953. **[Proceedings of the Fourth Conference of the International Society for Research on Biological Rhythm, Basle. September 1953.]** *Acta med. scand.*, 1955, **152**, Suppl. 307, pp. 199.

PETRÉN, T. (42–47), development of the diurnal rhythm of liver glycogen (chick embryo, chicken) and the effect of inverting the rhythm of light and feeding (chicken); SOLLBERGER, A. (69–75), diurnal variations in scatter of biological values; MILLS, J. N. and STANSBURY, S. W. (95–96), diurnal variations in behaviour of renal tubule towards Na, K and chloride (man); BALZER, E. and WERNER, K. (124–131), rhythm of exocrine pancreas enzyme secretion; PIERACH, A. (159–166), night work and shift work by healthy and diseased persons; BERINGER, A. (172–174), diurnal variations in liver fat and liver glycogen (man, animals).

Proceedings of the XXIV Scandinavian Congress for Internal Medicine, Stockholm, September 1954. *Acta med. scand.*, 1955, **152**, Suppl. 308, pp. 55.

CHRISTENSEN, B. (23), thyroid function and iodine metabolism (man); DAM, D., GEILL, T., LUND, E. and SØNDERGAARD, E. (38–39), clinical experience with newer anticoagulants, including effects of vitamin K preparations; COLLDAHL, H. (46–47), disturbances of nicotinic acid metabolism in patients with liver parenchymal injury or disorders with insufficient gaseous exchange; SIURALA, M. (51), gastric mucosal changes in pernicious anaemia, Addisonian and tapeworm; HOFF JØRGENSEN, E. and LANDBOE-CHRISTENSEN, E. (52–53), histotopographic localisation of the vitamin B_{12} binding factor in the fundus, pylorus and duodenum; in the pig the highest activity was in the glandular layers of the pyloric mucosa, followed by the Brunner's glands layer of the duodenum and the glandular layers of the mucosa of the fundus; material obtained from man at operation was much less active than corresponding material from the pig; HALLBERG, L. (54–55), effect of treatment of pernicious anaemia on total Hb and carboxyhaemoglobin; with remarks on the life span of red cells.

Proceedings of the Nutrition Society, 1956, **15**, 1–99.

Conference held in July 1955 on the nutritional work of FAO, WHO and UNICEF, contributions being made by DOROLLE, P. (1–4), international co-operative activities in the field of nutrition; AYKROYD, W. R. (4–13), FAO and nutrition; BURGESS, R. C. (13–21), WHO and nutrition; The Secretariat of the U.N. Children's Fund, UNICEF (22–29), assistance for child nutrition; ROSS, M. A. (30–35), nutrition and home economics programme in Egyptian villages; POSTMUS, S. (35–40), nutrition work in Burma past and present.

Conference held in September, 1955 on cholesterol and fat metabolism in relation to nutrition and disease. COOK, R. P. (41–45), chemistry and biochemistry of the sterols; LOVERN, J. A. (46–51), methods for investigating cholesterol and associated lipids; BOYD, G. S. and OLIVER, M. F. (52–61), cholesterol metabolism; RANNIE, I. (61–66), experimental cholesterol atherosclerosis; FULLERTON, H. W. (67–71), relation of lipaemia to thrombosis and atheroma.

Conference held in October 1955 on energy expenditure in man. DOUGLAS, C. G. (72–77), experimental methods for determining energy expenditure; WOLFF, H. S. (77–80), techniques for measuring energy expenditure; EDHOLM, O. G. (80–83), energy expenditure in relation to nutrition; PASSMORE, R. (83–89), daily energy expenditure; DURNIN, J. V. G. A. (89–93), energy expenditure in the elderly; NOLTIE, H. R. (93–99), energy expenditure in athletics.

Bericht über die 67. Jahresversammlung der Schweizerischen Gesellschaft für Analytische und Angewandte

Chemie. September 1955. **[Report of the 67th Meeting of the Swiss Society for Analytical and Applied Chemistry. September 1955.]** *Mitt. Geb. Lebensmittel. Hyg.*, 1955, **46**, 453–568.

The first session dealt with legislation about food with papers by HÖGL, O. (453–463) on development and fundamentals of federal food legislation; DESHUSSES, J. (464–474), chemical impurities in food; ACHERMANN, F. (475–482), prevention of falsification in trade in foods, and others. At the second session the papers included, MATTHEY, E. and RAMUZ, A. (503–508), estimation of malic acid; SCHÜRCH, A. (509–515), respiration apparatus for use with rats; TEMPUS, P. and HÖGL, O. (527–536), quantitative estimation of carnosine by paper chromatography; BOVAY, E. (540–568), estimation of K, Ca, Mg and Na in plant ash by flame spectrophotometer and of N by semi-micro distillation.

Proceedings of the Biochemical Society. November 1955. *Biochem J.*, 1956, **62**, 1P–9P.

DRÈZE, A. (3P), tryptophan stability during alkaline hydrolysis of protein; OLLEY, J. and DAWSON, R. M. C. (5P–6P), paper chromatography of hydrolysis products of phospholipins; JONES, N. R. (7P–8P), estimation of free sugar in codling muscle; LEWIS, C. A. (9P), low-sodium milk for clinical use.

Proceedings of the Biochemical Society. December 1955. *Biochem. J.*, 1956, **62**, 11P–19P.

RATTRAY, J. B. M. and COOK, R. P. (11P), lipid of livers of cholesterol-fed rats; SMITH, E. L., PARKER, L. F. J. and GANT, D. E. (14P), antimetabolites from vitamin B_{12}; CUTHBERTSON, W. F. J., GREGORY, J., O'SULLIVAN, P. and PEGLER, H. F. (15P), anti-vitamin B_{12} activity of compounds related to cobalamin.

Proceedings of the Biochemical Society. January 1956. *Biochem. J.*, 1956, **62**, 21P–38P.

HUNTER, G. and STOTT, F. D. (29P), micro estimation of magnesium; ACKLAND, J. D. (30P), estimation of serum protein-bound iodine; CLARK, C. M., NAISMITH, D. J. and MUNRO, H. N. (38P), estimation of aluminium with ethylenediamine tetra-acetic acid.

Proceedings of the Physiological Society. December 1955. *J. Physiol.*, 1956, **131**, 1P–23P.

BUXTON, J., MAYER, A. and SINCLAIR, H. M. (17P–18P), histamine level in vitamin B_6 deficiency in the rat; DURNIN, J. V. G. A. and MIKULICIC, V. (22P–23P), effect of graded exercise on energy expenditure in man.

Proceedings of the Physiological Society. January 1956. *J. Physiol.*, 1956, **131**, 25P–37P.

MACDONALD, I. and THOMAS, G. A., hepatic fibrosis on fat-free diet (25P).

Gesellschaft für Ernährungsphysiologie der Haustiere. 5. Tagung, Bad Homburg, October 1955. **[Society for the nutritional physiology of domestic animals. 5th Session in Bad Homburg, October 1955.]** *Ztschr. Tierernährung Futtermittelk.*, 1955, **10**, 378–383.

The theme for the meeting was the technique of practical feeding experiments on animals: KIRSCH (378–379), methods with dairy cows and pigs, with suggestions for the breeding of "standard animals", especially pigs: the use of special centres for the statistical analysis of results and of centres for analysis of feedingstuffs; WITT (379–380), methods with calves; FEWSON (380–381), statistical analysis; FANGAUF (381–382), techniques with poultry; BRONSCH (382–383), use of radio-active tracers; WITT (383), fat content of milk of pastured cows.

Symposia of the Society for Experimental Biology No. 8, 1954, pp. vi + 516. Cambridge Univ. Press.

The theme of the meeting was "Active transport and secretion". Most of the articles are reviews and deal with physiological concepts and laws relating chiefly to the movement of Na and K and sugar into and out of cells, particularly erythrocytes, and isolated tissues. DAVIES, R. E. (453–475), in his review of "Relations between active transport and metabolism in some isolated tissues and mitochondria" makes an appeal for data on "number of ions moved actively in relation to the number of molecules of oxygen used or substrate metabolized, and also, if this can be estimated, the amount of energy needed to drive the active transport relative to the amount of energy made available from metabolism".

BRAMBELL, F. W. R. and HEMMINGS, W. A. (476–489) deal with "Active transport through embryonic membranes" but the transport measured is of antibodies. FRAZER, A. C. (490–499) discusses the "transport of lipid through cell membranes".

Proceedings of the Royal Society of Medicine, Section of Pathology, April 1955. *Proc. Roy. Soc. Med.*, 1955, **48**, 911–918.

DUBOS, R. J., SMITH, J. M. and SCHAEDLER, R. W., metabolic disturbances and infection (mouse).

Section of Odontology, March 1955. *Proc. Roy. Soc. Med.*, 1955, **48**, 983–992.

Schweizerische Gesellschaft für Pädiatrie. Jahresversammlung Aarau, Juni, 1955. **[Swiss Paediatric Society. Annual meeting Aarau, June 1955.]** *Ann. paediat.*, 1956, **186**, 90–125.

Among the 21 papers read at this meeting the following were of interest in the field of nutrition. STALDER, G. (90–91) dealt with the renal action of vitamin D. Familial rickets resistant to vitamin D was discussed by TOBLER, R., PRADER, TAILLARD and DEBRUNNER (91–92), anthropometry of growth by LELONG, M. (100) and the basal metabolism of obese infants by JUILLARD, E. and DUBOIS,

R. (108). ZIEGLER, E. (110–111) discussed fluoridation of milk ; he calculates that when water is fluoridated at 1·5 p.p.m. the infant fed on dried milk may receive up to 7 times the physiological optimum dose.

American Heart Association, 28th Scientific Sessions, New Orleans, La., October 1955. *Circulation*, 1955, **12**, 675–794.

(117–123), quality of wool, fleece weight and mutton quality of the improved Texel sheep ; KETELAARS, E. H. (129–140), solids-not-fat of milk from the standpoint of the breeder ; SCHIERE, C. (144–151) and ADAMSE, G. (152–156), the problem of payment for milk so as to take composition into account.

Deutschen Gesellschaft für Züchtungskunde, October 1955, Munich. **[German Society of Animal Breeding, October 1955, Munich.]** *Zuchtungskunde*, 1955, **27**, 197–294.

There are 4 papers of some nutritional interest : TRAUTWEIN, K. (200–206), milk production on peasant farms, with a plea for study of composition of milk as affected by amino acid composition of feedingstuffs and by vitamin supply ; KOCH, W. (252–256), hormones in relation to milk formation ; HARING, F. (270–289), inheritance of capacity to produce the major components of milk ; SCHÄPER, W. (289–294), milk yield and " constitution " in cows.

Proceedings 31st Annual Convention of the Philippine Veterinary Medical Association, May 1954. *Philippine J. Animal Indust.*, 1954, **15**, 101–275.

OLIVARES, E. O. and MASANKAY-ARENAS, L. (237–245), cow manure extract for pigs ; PARIÑA, S. L. (255–260), maize in laying mash under Philippine conditions ; LOOSLI, J. K., VILLEGAS, V. and YNALVEZ, L. A. (265–270), composition and digestibility of Philippine forages.

9. FOOD AND AGRICULTURE ORGANIZATION (AND OTHER ORGANIZATIONS) OF THE UNITED NATIONS

Monthly Bulletin of Agricultural Economics and Statistics.
Vol. 5, No. 3, March 1956, pp. 48. Price $0.50.
p. 13. Potential uses of rice in Germany. The country should be of special interest to rice exporters because of its breweries, its linen industry which requires starch and its intensive animal production.
Vol. 5, No. 4, April 1956, pp. 48. Price $0.50.
Vol. 5, No. 5, May 1956, pp. 52. Price $0.50.
p. 1. Input-output work as a basis for development planning. The problems in applying input-output work to agriculture are discussed.
Vol. 5, No. 6, June 1956, pp. 48. Price $0.50.
p. 1. The agricultural policy of the U.S.S.R. and the sixth five-year plan.
p. 9. The new international wheat agreement.

Yearbook of Food and Agricultural Statistics. 1955, Vol. 9, Part 1. Production. Rome, Italy, 1956. Price $3.50.

Nutritional Studies No. 14. Protein malnutrition in Brazil. Rome, Italy, March 1956, pp. vi + 40. Price $0.50.

This third study of protein malnutrition (for the others in Africa and Central America see Vol. 22, p. 278 ; Vol. 25, p. 306) is based on questionnaires sent to pediatricians and on the authors' observations made during brief visits to 5 state capitals, Recife, Rio de Janeiro, Belo Horizonte, Belem de Para and Porto Alegre. The condition, known locally as *distrofia pluricarencial* and thought to be the same as kwashiorkor in Africa, was common in the first 3 cities. Most frequent signs were oedema and failure of growth. Level of albumin in blood was low and the tendency, seen elsewhere, for that of globulin to rise did not appear. Changes in skin and hair were variable ; those in hair could not be regarded as diagnostic. Increase in size of liver also varied and, as in other areas, the degree of fatty change was not a measure of the severity of the disease. Cirrhosis was not common and primary carcinoma of the liver seldom occurs.

In treatment the best results have been with a diet rich in protein on the basis of dried skimmed milk supported, if need be, by blood transfusions, an antibiotic and vitamins A and C. These are the essential forms ; the results for others which have been tried are summarised.

From the food balance sheets for 1947 and 1952 there are indications that the amount of protein available per head of population may be falling in Brazil. Differences in supplies between districts may be considerable. Government's action has been to set up plants for drying surplus milk, to prepare plans for a fish flour factory and to experiment with protein-rich plant foods. Education of mothers in nutrition and schemes for supplementary feeding of children should be extended beyond their present ranges. Suggestions are made for further biochemical and pathological studies of protein deficiency in man, facilities for which already exist in Brazil.

Report of the Eighth Session of the Conference, 4-25 November 1955. Rome, Italy, March 1956, pp. lv + 270.

The Conference adopted 55 resolutions. By the first, Member Nations on the occasion of the tenth anniversary of the founding of FAO " ratified their accession to the purposes and principles laid down in the Constitution of the Organization ". Many of the others were concerned with administration. Particular resolutions requested the Director-General to strengthen the Organization's work on education, nutrition and home economics with special reference to proper food selection and preservation and expressed the Conference's interest in the proposal for the establishment of a Special United Nations Fund for Economic Development. The use of surpluses for raising the nutritional levels of vulnerable and underprivileged groups and for aiding economic development was approved with a further resolution on the need for adequate intergovernmental machinery for consultation on these matters. The Conference agreed to continue to support, with the money available, the work on the broad field of milk and its part in child nutrition but, at the same time, considered that 2 subjects, the nutrition of aged people and the enrichment of foods with concentrates were deserving of more attention in the future.

10. DEPARTMENTAL AND OTHER REPORTS

UNITED KINGDOM

The Hannah Dairy Research Institute, Kirkhill, Ayr. Report for the Three Years ending 31st March, 1956. Pp. 44. (Twenty-fifth to Twenty-seventh Annual Reports combined.)

Effect of hormone preparations (containing thyrotropin and the luteinising and follicle stimulating hormones) on the composition of milk and carotene and vitamin A metabolism of cows and goats.
Formation of lactose in the mammary gland.
Muscular dystrophy and vitamin E (calf).
Magnesium metabolism with reference to hypomagnesaemic tetany in calves.
Energy metabolism of feedingstuffs fed at different levels and effect of frequency of feeding, exercise and previous diet.
Energy metabolism of lower steam-volatile fatty acids in sheep.
Physiological response of cattle to climate, especially temperature and humidity,
Protein stability in milk.

Milk Marketing Board, Thames Ditton Surrey. 6th Report of the Production Division, 1955/56. Pp. 118.

INDIA

Annual Report of the Indian Veterinary Research Institute, Mukteswar and Izatnagar for the Year 1952-53 (1955). Pp. 114.

Tobacco seed cake as feed for cattle.
Juar (*Andropogon sorghum*) husk as feed for cattle.
Nutritive value of untreated, lime-treated and alkali-treated straws.
Utilisation of nitrogen, calcium and phosphorus from paddy straw.
Optimum level of fat in the ration of ruminants.
Nutritive value of tree leaves ; Gaujina (*Saurauja napaulensis*), Rohini (*Mallotus philippinensis*), Jaman (*Eugenia jambolana*), Kumbhi (*Careya arborea*), Tendu (*Diospyros tomentosa*), Kanju (*Holoptelea integrifolia*).
Ensiling tree leaves.
Histopathological studies of lambs under conditions of vitamin A and calcium deficiency.
Studies with sheep of chemical and morphological constituents of blood at different iron intake levels.
Processed cow manure as ingredient of poultry rations.
Feeding bajra to poultry as sole cereal.
Semen production in buffaloes at different levels of protein intake.

SOUTH AFRICA

The South African Institute for Medical Research, Johannesburg, Annual Report for the Year ended 31st December, 1955. Pp. 109.

Calcium and iron metabolism in the South African Bantu.
Incidence of clinical rickets in urban and rural Bantu children.
Studies on atherosclerosis in Bantu and white subjects.
Parasitism and nutritional state.
Serum electrolyte pattern in kwashiorkor.

TANGANYIKA

Annual Report of the Veterinary Department for the Year 1954. Vol. 2, Research and Statistics. Pp. 52.

Mineral imbalance in stock ; phosphorus, trace elements and fluorine. Occurrence of fluorosis.
Physiology of the hump in Zebu stock.

UNITED STATES OF AMERICA

68th Annual Report of the Pennsylvania Agricultural Experiment Station for the Fiscal Year ended June 30, 1955. Pp. 20.

Soft phosphate with colloidal clay as a source of phosphorus in swine feeds.
Factors affecting the vitamin content of canned foods.
Evaluation of grasses and legumes for use as poultry pasture.
Interrelations between nutrition, microbial flora of the rumen and " X " disease (hyperkeratosis) in cattle.
Physical and chemical properties of fats and fatty acid derivatives in relation to their composition, structure and utilisation.
Relationship of vitamin intake to growth, to longevity and to well-being (freedom from abnormal external and internal conditions) of the rat.
The nutritive value of grass silage as affected by species and stage of maturity.
The losses of nutritive value of grass silage in tower silos as affected by method of preservation.
The nutritive value of hay as affected by the method of curing.
Influence of soils and fertilisation on the composition and nutritive values of foods and feeds.
The efficiency of utilisation of normal diets of equal metabolisable energy but differing in protein, carbohydrate, or fat content.
The effects of specific food nutrients on energy metabolism.
The role of antibiotics in protein metabolism and growth.
The relation between age and nutritional requirements of dairy calves.
Study of riboflavin deficiency in eggs affecting hatchability.
The influence of energy-fibre concentrations and protein source of the diet on certain egg quality characteristics.
The etiology of calf scours and evaluation of control measures.
Ascorbic acid metabolism of the human.

Sixty-eighth Annual Report of the New York State College of Agriculture at Cornell University and the Cornell University Agricultural Experiment Station for the Year 1954-55. Pp. 126.

Relation of feeding and management to cause of " stiff lamb " disease.
Comparison of various protein supplemental mixtures, and effects of vitamin and antibiotic supplements for growing and fattening pigs.
Protein requirements of growing, fattening lambs.
Nutritional requirements of herbivora as studied by purified-diet methods.
Physiology and metabolism of fats and related constituents in animals.
Effect of curing methods upon feeding value of hay.
Investigations with young dairy calves on effects of composition of dry starters, levels of starter and hay consumption, rumen inoculation, levels of milk consumption, and antibiotics.
Requirements and functions of cobalt in rations of livestock.
Causes and prevention of ketosis in ruminants.
Development and use of indirect methods for measurement of digestibility and rate of consumption of feeding-stuffs, particularly forages, by ruminants.
Value of molasses and urea in rations for dairy cattle.
Influence of feeding and management practices of the young upon early rumen development and subsequent mature performance.
Nutritional requirements of baby pigs.

Whole body composition and carcase studies of cattle at different ages and at three nutritional levels.
Chemical and biological evaluation of nitrogenous requirements of animals.
Digestibility and dry matter consumption of various feeds for beef cattle.
Influence of antibiotics in rumen digestion and synthesis.
Relative value of roughage and concentrates for ruminants fed for production.
Development of dry diets for minks.
Value of fat (beef tallow) in ration for fattening lambs.
Investigations in body composition of swine.
Relationship of time of cutting to digestibility of different forages.

INTRODUCTION

To define a pathological state in pregnancy is sometimes difficult because knowledge of changes which might be accepted as normal and physiological is not precise. It becomes increasingly clear that metabolism generally and the whole *milieu intérieur* are grossly altered by pregnancy and that the "normality" of any biochemical finding in pregnancy cannot be decided by reference to the non-pregnant state. Some consideration of changes in haemopoiesis which occur in normal, healthy women during pregnancy is therefore an essential preliminary to the discussion of anaemia in pregnancy.

THE BLOOD IN NORMAL PREGNANCY

There is general agreement that, in terms of a given volume of blood, the haemoglobin, the red cells and the packed cell volume decrease during pregnancy in healthy women who are not taking iron medicinally: the "physiological anaemia of pregnancy". Some figures from the literature.

TABLE I.—HAEMOGLOBIN IN NON-PREGNANT AND PREGNANT WOMEN (NUMBER OF WOMEN IN BRACKETS)

Authority and Place	Haemoglobin, g. per 100 ml.									
	Non-pregnant	*Pregnant*								
Medical Research Council (1945) (United Kingdom)	13·9 ± 1·4 (770)	*Month 1* 13·4 (13)	*2* 13·2 (92)	*3* 13·2 (90)	*4* 12·6 (58)	*5* 12·8 (71)	*6* 12·0 (103)	*7* 12·1 (88)	*8* 12·1 (140)	*9* 12·2 (75)

which illustrate these changes, are given in Tables 1 to 3. The fall begins during the first trimester and the lowest point is usually reached early in the third trimester.

Haemoglobin Concentration (*Table 1*)

In studies in which pregnant and non-pregnant women were compared, haemoglobin towards the end of the first trimester of pregnancy averaged about 5 per cent. (0·78 g. per 100 ml.) and at the lowest point about 15 per cent. (2 g. per 100 ml.) below the mean for non-pregnant women, after which there was a slight rise, of the order of 2 per cent. (0·25 g.), to term. There is less information about changes which occur after delivery. Tysoe and Lowenstein (1950) reported haemoconcentration immediately after delivery, and Wills *et al.* (1947) and Lundström (1950) found a rise in haemoglobin concentration on the first day *post partum.* Thereafter haemoglobin falls by the middle of the first week of the puerperium to a little below the lowest level found in pregnancy (Wills *et al.*, 1947 ; Tysoe and Lowenstein, 1950 ; Turnbull, 1956). Normal non-pregnant level is regained by the third month of the puerperium, but there is no evidence to show the earliest time at which it is reached.

In healthy non-pregnant women the haemoglobin concentration, measured by standard techniques (for a note on technique see p. 867), is on the average about 13·9 g. per 100 ml. The lowest average levels recorded during pregnancy are between 11 and 12 g. per 100 ml. (74 to 81 per cent. Haldane) in most series, and where the data have been treated statistically the standard deviation of the mean is about 1 g. An exception is Lundström's (1950) reported mean, in over 100 Swedish women at term, of only 9·8 g. per 100 ml. In 98 healthy, non-parous women an average of 12 g. per 100 ml. is claimed. The admitted discrepancy between these and other data for Swedish women is attributed by Lundström himself to "bias" on the part of his technical assistant. Clearly the data for his pregnant women have no value in absolute terms. At the other extreme 21 pregnant women in Boston, whose blood was examined by Rath *et al.* (1950), had an average haemoglobin value which did not fall below 12·7 g. per 100 ml.

Packed Cell Volume (*Table 2*)

The packed cell volume falls in parallel with the haemoglobin concentration to reach an average of about 34 per cent. at its lowest point ; the value generally accepted as normal for non-pregnant women is 40 to 42 per cent. The average lowest values found by Rath *et al.* (1950), 36·7 per cent., and by Hamilton (1950), 38·3 per cent., were exceptional. Like the haemoglobin concentration, the packed cell volume rises slightly towards term and reaches the range for non-pregnant women by about the third month of the puerperium.

Red Cell Count (*Table 3*)

There is relatively little information about the red cell count; what evidence there is suggests that it, too, runs parallel to the haemoglobin concentration.

Mean Cell Volume

There is general agreement that the mean cell volume does not change (Roscoe and Donaldson, 1946; Wills *et al.*, 1947 ; Rath *et al.*, 1950 ; Merivale and Richardson, 1950); but Tysoe and Lowenstein (1950) found that the size of cells "increased throughout pregnancy, although the values remained within normal limits", Edgar and Rice (1956) found a similar small rise and Lundström (1950) records a decrease during the last two months. The mean cell diameter as measured by Merivale and Richardson (1950) was slightly below the mean for non-pregnant women, which means that the cells were more spherical; Elliott (1944) found no deviation from the non-pregnant.

Mean Cell Haemoglobin Concentration

The mean cell haemoglobin concentration appears to vary little from an average of about 32 to 33 per cent. during pregnancy. Lundström (1950), Rath *et al.* (1950), Tysoe and Lowenstein (1950), Lund (1951) and Turnbull (1956) found no appreciable change ; Benstead and Theobald (1952) and Davis and Jennison (1954) showed a fall of about 0·5 per cent. during the last trimester in two small series of women, and Edgar and Rice (1956) showed in 25 women a mean fall from 32·6 per cent. at 16 weeks to 30·2 per cent. at term ; Roscoe and Donaldson (1946) found a small rise during pregnancy in a series of 20 women. The mean cell haemoglobin similarly remains almost constant throughout pregnancy, although Rath *et al.* (1950) and Lundström (1950) reported a small decrease during the last month.

Individual Variation

All reports emphasise that the individual variation is much greater in pregnant than in normal non-pregnant women, so that, although the trends indicated above represent those in the *average* healthy, pregnant woman, they may not hold for a particular individual, and averages from small series must be accepted with reserve. For example, some women show no fall in haemoglobin concentration during pregnancy, or even a slight rise, and others may show a considerable fall. It appears

TABLE 2.—PACKED CELL VOLUME IN NON-PREGNANT AND PREGNANT WOMEN (NUMBER OF WOMEN IN BRACKETS)

Authority and Place	Packed cell volume, per cent.									
	Non-pregnant	*Pregnant*								
Roscoe and Donaldson (1946) (Edinburgh)	42·3 ± 3·9 (20)	*Weeks 8–16* 39·2 ± 3·2 (20)				*20–27* 37·0 ± 2·0 (20)			*33–38* 36·4 ± 2·2 (20)

Rath *et al.* (1950) (Boston, U.S.)		*Month 2* 39·5 (12)	*3* 38·8 (13)	*4* 37·2 (9)	*5* 37·0 (16)	*6* 36·7 (15)	*7* 37·2 (18)	*8* 37 (17)	*9* 37·9 (9)	
Lund (1951) (New Orleans, U.S.)			*Week 12* 40 (3)	*16* 39 (8)	*20* 37 (9)	*24* 35·5 (6)	*28* 35·2 (6)	*32* 34·2 (7)	*36* 34·4 (7)	*40* 35·7 (8)
Benstead and Theobald (1952) (Bradford)				*Week 16* 39·8 (36)	*20* 38·3 (36)	*24* 37·1 (36)	*28* 35·5 (36)	*32* 34·6 (36)	*36* 35·5 (36)	*40* 36·8 (36)
Edgar and Rice (1956) (Nottingham)				*Week 16* 37·8 (25)	*20* 36·2 (25)	*24* 34·4 (25)	*28* 34·2 (25)	*32* 33·0 (25)	*36* 33·0 (25)	*40* 36·3 (25)

that age has little or no effect, and parity a doubtful effect, on these changes. Roscoe and Donaldson (1946) found in one of their series, but not in another, a greater fall in haemoglobin concentration during pregnancy in older mothers, whatever the parity, but Lundström (1950), Magee and Milligan (1951) and Walsh *et al.* (1953) found no association with age. Multiparae showed a greater fall in haemoglobin concentration than primiparae in the studies of Wills *et al.* (1947), Magee and Milligan (1951) and in one series of Roscoe and Donaldson (1946), but no difference with parity was found by Lundström (1950), Walsh *et al.* (1953), or Roscoe and Donaldson in their second series.

To summarise, the haemoglobin concentration, the red cell count and the packed cell volume all decrease during the first 7 or 8 months of normal pregnancy and rise again slightly towards term; the size of the red cell and its haemoglobin content do not alter.

Dilution

The plasma volume rises, on the average, by about 35 to 40 per cent. during pregnancy, but there is an almost incredibly wide range in clinically well women. For example, Lund (1951) found the extremes of the rise during pregnancy in 66 women to be 14 and 121 per cent. There is no explanation of this variation. The maximum plasma volume is reached at about the 32nd to 36th week of pregnancy, after which there is a slight decline to term. It is estimated that total red cell mass increases by about 17 per cent. and with less variation than plasma volume; it rises continuously to the end of pregnancy. Plasma volume decreases rapidly to normal after parturition, with little, if any, rise in haemoglobin concentration, and there is a suggestion (Verel *et al.*, 1956) that a large quantity of red cells may be removed from the circulation at this time. They may be stored in the spleen.

The dilution of red cells which occurs in pregnancy is due to the disparity between the increases in plasma and red cells, and the wide variations in the degree of dilution are due to the variation in the increase of plasma. The concept of "dilution" is perhaps unfortunate if it gives the impression that the red cell concentration is less than it should be. The blood is dilute only in comparison with the blood of non-pregnant women. The two blood components are controlled independently by different mechanisms and for different purposes. The red cell mass increases in response to a requirement for increased oxygen-carrying capacity. The plasma volume increases for quite different purposes, the most important of which is to fill the increased vascular bed.

TABLE 3.—Red Cell Count in Non-pregnant and Pregnant Women (Number of women in brackets)

The Effect of Iron

There can be little doubt that the changes in the blood are considerably modified when extra iron is given to the pregnant woman.

Haemoglobin Concentration

Lundström (1950), Benstead and Theobald (1952), Davis and Jennison (1954), Fisher and Biggs (1955) and Edgar and Rice (1956) have all reported that the mean haemoglobin concentration in women given extra iron by mouth rose during pregnancy, sometimes to non-pregnant levels, and Wills *et al.* (1947), Lund (1951) and Magee and Milligan (1951) were able to arrest the usual fall. Gerritsen and Walker (1954) say that Bantu women, with an exceptionally high intake of iron, have no fall in mean haemoglobin concentration during pregnancy. The very small fall in haemoglobin concentration found for a group of Boston women by Rath *et al.* (1950) is remarkably close to that in other series in which medicinal iron was given, and suggests that those women may have been taking iron supplements of their own accord.

Other Values

The usual falls in packed cell volume and red cell count can be similarly modified by iron (Lundström, 1950; Lund, 1951; Benstead and Theobald, 1952; Wills *et al.*, 1947; Davis and Jennison, 1954; Edgar and Rice, 1956). The mean cell haemoglobin concentration and mean cell volume are not appreciably altered by iron, although Lundström and Edgar and Rice found higher values in their patients given iron, and Benstead and Theobald were able to raise the average mean cell haemoglobin concentration to the high value of 34 to 36 per cent. by the end of pregnancy.

The Evidence for Iron Deficiency

The finding that the haemoglobin concentration of the blood can be increased by giving iron raises the question whether the usual fall in pregnancy is truly normal or should be regarded as a sign of iron deficiency. It suggests cure by replacement, the classical test of deficiency, and other evidence is believed to support that suggestion.

Free Protoporphyrin

For example, the mean concentration of free protoporphyrin in the red cell was found to be raised during pregnancy (Fay *et al.*, 1949; Lund, 1951; Ventura and Klopper, 1951*a*) and is known to be increased in hypochromic anaemia (Cartwright *et al.*, 1948), but the rise in pregnancy, which varies widely in magnitude, is not necessarily analogous. Ventura and Klopper stated that free protoporphyrin values "are increased whenever the linkage between iron and protoporphyrin is disturbed. Anaemia is not the only condition which may disturb this linkage; it is just as reasonable to assume that pregnancy may itself be the disturbing factor."

Serum Iron

The average serum iron concentration is reduced at term to about 35 per cent. below the mean in non-pregnant women (Fay *et al.*, 1949; Lundström, 1950; Ventura and Klopper, 1951*a*; Mukherjee and Mukherjee, 1953), and the iron-binding capacity is raised, so that the percentage saturation of iron-binding protein is low. Similar changes are found in iron-deficiency anaemias (Laurell, 1947; Smith, 1952). Taken together with the fact that the serum iron can be raised by iron in pregnancy, as in iron-deficiency anaemia (Lundström, 1950; Davis and Jennison, 1954; Mukherjee and Mukherjee, 1953), and does not fall at all in women on diets rich in iron (Gerritsen and Walker, 1954), these findings are assumed by many to be strong evidence that the usual changes in the blood in pregnancy are due to deficiency of iron, but the analogy must be drawn with great caution. In health the serum iron shows immense individual variability, even from hour to hour (Jacot, 1951; Fowler and Barer, 1952; Howard, 1953; Rechenberger and Hevelke, 1955), and the processes which determine the changes are not understood. Serum iron is low during the first week of the menstrual cycle (Powell, 1944; Dahl, 1948; Smith, 1952) and during acute infections. It falls whenever production of red cells rises (Wasserman *et al.*, 1952; Finch and Finch, 1955), and may be low even when large stores of iron can be demonstrated histologically in the marrow (Davidson and Jennison, 1952). Goldeck *et al.* (1954) have shown that the concentrations of haemoglobin and serum iron are not correlated in pregnancy. In any event, the total amount of iron circulating in the plasma is probably raised, because of the increased plasma volume of pregnancy.

Iron-binding Capacity

The iron-binding capacity of the blood is even less well understood. It is now known to depend on the β_1-globulin transferrin, which is thought to act specifically as an iron transporter. Ventura and Klopper (1951*a*) attribute the raised iron-binding capacity to "the vastly increased turnover of iron in late pregnancy", but it may simply be associated with the rise in the concentration of plasma globulin. Gerritsen and Walker (1954) found an increased iron-binding capacity in the

blood of Bantu women who showed no reduction of either haemoglobin or serum iron.

The concept of *saturation* of iron-binding capacity is not helpful, since saturation occurs only when large quantities of iron are released into the bloodstream, either by haemolysis or after intravenous injection of iron. Laurell (1947) believed that the low saturation during deficiency of iron and in pregnancy presents a condition favourable for absorption of iron from the gut, but the saturation of 30 or 40 per cent. in non-pregnant women should provide an adequate margin for any further transport of iron which is required. A more logical explanation might be that the additional facilities for carriage of iron and the "enhanced power and speed in coping with an influx of iron" (Ventura and Klopper, 1951*b*) are needed to deal with the relatively large amount of iron returned to stores at the end of pregnancy, when the blood volume returns to normal. The amount is estimated to be equivalent to from 54 g. haemoglobin (Lund, 1951) to about 100 g. (Lowenstein *et al.*, 1950).

Serum Copper

The copper content of serum in pregnancy is above that of non-pregnant women (Fay *et al.*, 1949; Röttger, 1950; Ventura and Klopper, 1951*a*; Lahey *et al.*, 1953), as it is in iron-deficiency anaemia (Cartwright *et al.*, 1948). But the copper content of plasma is raised in many conditions (Lahey *et al.*, 1953) and is not related to serum iron. Its role is not well understood.

What, then, are the grounds for regarding the fall in haemoglobin concentration during pregnancy, which occurs in healthy normal women, as an indication of deficiency of iron? The low serum iron, the increased iron-binding capacity, the high serum copper and the high free protoporphyrin in red cells have been discussed. None of these specifically indicates deficiency of iron, nor does the peripheral blood picture. The cells are of normal size and the mean cell haemoglobin concentration, regarded by Whitby and Britton (1953) as "the true indicator of the presence or absence of iron deficiency", is normal. There remains the belief that because the haemoglobin concentration in the blood can be raised by giving iron, there must be deficiency of iron. Widdowson and McCance (1936), Fowler and Barer (1941) and Garry *et al.* (1954) have shown that iron will raise haemoglobin concentration even in normal persons, and in one of Fowler and Barer's series the haemoglobin fell again to its initial level even while iron was still being given. Iron appears to provide a specific, though temporary, stimulus to erythropoiesis. Wills *et al.* (1947), commenting on the rise in haemoglobin level which followed administration of iron in their series of pregnant women, say that ". . . judging from the nature of the changes in the haematological picture, [the iron] cannot have acted by correcting a latent hypochromic anaemia". Lund (1951) too saw that the total mass of haemoglobin could be increased in pregnancy by giving iron when there was no evidence of deficiency.

The fact that the fall in haemoglobin concentration in normal multigravidae has been found to be greater than in primigravidae (Goodall and Gottlieb, 1936; Wills *et al.*, 1947; Magee and Milligan, 1951) has been interpreted as indirect evidence of depletion of iron, accentuated by repeated pregnancy. But the blood pictures of primigravidae and multigravidae are not directly comparable; there is evidence of a relatively greater rise in plasma volume in multigravidae (Thomson *et al.*, 1938; McLennan and Thouin, 1948; Kjellberg *et al.*, 1950; Lowenstein *et al.*, 1950) and a lower haemoglobin concentration is to be expected.

The Significance of Haemodilution

The problem might be viewed in another way. Is there any clinical disadvantage in the "physiological anaemia of pregnancy"? The rise in cardiac output in pregnancy is closely parallel to the rise in total blood volume. It seems that, on the average, a volume equivalent to the total blood volume is pumped through the heart each minute at all stages of pregnancy. If the pregnant woman's blood has a relatively low oxygen-carrying capacity, blood will return to the heart from her peripheral circulation with less than the normal quantity of oxygen. But it has been shown by cardiac catheterisation (Palmer and Walker, 1949; Bader *et al.*, 1955) that the arteriovenous difference in oxygen content in normal pregnancy, at the time when dilution is greatest, is only 3·5 volumes per cent., so that blood is returned to the heart at a higher oxygen tension than usual, which is explicable in terms of function. Of the extra 1100 ml. of blood pumped into the systemic circulation each minute in late pregnancy, only about 600 ml. are required for carriage of extra oxygen, mostly to the uterus and its contents (Romney *et al.*, 1955). The remaining 500 ml. circulate in the skin, mainly of the arms and hands (Abramson *et al.*, 1943; Burt, 1950), where they help to eliminate the heat generated by the foetus. It can be calculated that the usual fall in haemoglobin concentration occurring in pregnancy would be produced by adding 600 ml. of whole blood and 500 ml. of plasma to the blood of a non-pregnant woman. The mass of red cells increases on the average by about 17 per cent. during pregnancy and the velocity of blood flow by 20 per cent. or

more. The increase in weight of tissue requiring oxygen, calculated as the mean gain of weight during pregnancy minus the weight of additional blood, extravascular fluid and liquor amnii, is less.

The average increase of basal metabolic rate as measured by Bader *et al.* (1955) in terms of oxygen consumption per square metre of body surface was 9 per cent. above the DuBois standard for non-pregnant women. Since the rise to be expected from gain of tissue alone is of the same order, the absolute increase would be about 19 per cent., which is in good agreement with other estimates.

As might be expected from such a favourable physiological balance, the woman with "physiological anaemia of pregnancy" does not feel any benefit from having her haemoglobin raised by administration of iron, which is freely admitted, even where medication with iron in pregnancy is recommended as a routine. Fisher and Biggs (1955) say that the women in their series, who did not respond to iron and whose haemoglobin fell throughout pregnancy, were nevertheless "clinically well at all stages", and Magee and Milligan (1951) commented that in their large series "the great bulk of women, whether taking iron or not, were perfectly healthy and had no complaints, which raises the question whether a haemoglobin level raised by iron therapy is in itself an advantage".

A possible advantage which had been claimed for a high level of haemoglobin in pregnancy is that the woman is in a stronger position to withstand haemorrhage and even that she has less tendency to haemorrhage *post partum*. Wills *et al.* (1947) reported a greater incidence of haemorrhage in women who took no additional iron, but Lund (1951) found no significant difference in the incidence of haemorrhage between treated and untreated women, and Benstead and Theobald (1952) say that "the only disadvantage of maintaining the haemoglobin level at its normal value throughout pregnancy would appear to be a slightly increased risk of post-partum haemorrhage".

In general, there is no convincing published evidence that the normal pregnant woman is at an advantage if she takes extra iron. Perhaps the real benefit is not to the woman at all, but lies in that ". . . the confidence of both doctor and midwife, particularly in domiciliary practice, is greatly increased by the knowledge that the haemoglobin level is high at term" (Fisher and Biggs, 1955).

The Iron Balance in Pregnancy

The total amount of iron required for the products of conception and for the extra needs of the mother during pregnancy is about 650 mg.; 250 mg. for the foetus (Iob and Swanson, 1938; Widdowson and Spray, 1951; Rechenberger, 1955), 50 to 100 mg. for the placenta (Rechenberger, 1955) and 300 mg. for the mother's additional haemoglobin mass of about 90 g. (Berlin *et al.*, 1953; Lund, 1951). Almost all of the 650 mg. is required in the second half of pregnancy. At 20 weeks the foetus weighs about 300 g. and the placenta 180 g., accounting for perhaps 60 mg. iron, and the increase in total haemoglobin in the mother has not begun (Berlin *et al.*, 1953; White, 1951; Lund, 1951), so that the mean daily requirement for the last 20 weeks is about 4·2 mg. Not all of it need be supplied by the diet. The stores in a healthy woman at the beginning of pregnancy are probably about 1500 mg. (Haskins *et al.*, 1952), so that in fact the whole of the requirement of mother and foetus should theoretically be present from the start. In the absence of excessive loss at parturition, much of the additional haemoglobin will be retained and the iron will eventually be returned to stores. Thus only the iron used for the foetus and placenta and for blood lost at delivery will require replacement, and an uptake of between 3 and 4 mg. daily for the second half of pregnancy will suffice. Absorption of iron is regulated so that more is absorbed when stores are low (Balfour *et al.*, 1942), which may account for what occurs in pregnancy, when relatively large quantities may be absorbed even from a normal diet. Hahn *et al.* (1951) showed that as pregnancy progressed women absorbed increasing proportions, for example, about 3·7 mg. from 9 mg. of labelled iron in the last trimester. There is no direct information about the normal state of the body's iron reserves at the end of pregnancy, but there seems no reason to suppose that they are grossly depleted. The average diet in the United Kingdom in 1954 (Ministry of Agriculture, Fisheries and Food, 1956) supplied about 13 mg. iron daily, which should be more than adequate for a pregnant woman.

Possible Ill Effects of Medicinal Iron

If additional iron does no good to a normal pregnant woman, it should not be assumed that it does no harm. Hamilton (1950) has shown that the relative viscosity of the blood, but not that of the plasma, falls in parallel with the fall of haemoglobin concentration, to reach an average of 3·84 at 22 to 28 weeks, compared with a mean non-pregnant value of 4·61. This fall considerably diminishes the work of the heart and must help substantially to keep arterial blood pressure normal as the cardiac output rises.

There may be a danger of excessive storage of iron. The proportion absorbed falls as the dose rises, but the total amount absorbed increases. Hahn *et al.* (1951) found an average absorption of 9·5 mg. from 120 mg. in the second half of pregnancy. A common prescription is 200 mg. daily, or more.

Such extra iron will raise the haemoglobin, and will probably also fill the stores. Lund (1951) found the total mass of haemoglobin added in pregnancy to be 86 g. in normal, untreated women and 152 g. in those given 240 mg. iron daily. Normally only about 30 g. haemoglobin is lost at parturition and the remainder is broken down and the iron is returned to stores, but if the stores are already filled it must be laid down as haemosiderin. Large deposits of haemosiderin are rare in women (Finch and Finch, 1955), but more than half the Bantu described by Gerritsen and Walker (1954), whose intake of iron was very high and who showed no fall of haemoglobin in pregnancy, had haemochromatosis at autopsy (Walker, 1956).

Anaemia due to Deficiency of Iron

All that has been said so far refers to the normal healthy woman in pregnancy, but of course, true deficiency of iron can occur in pregnancy and has often been described.

Diagnosis

It has been shown that the haemoglobin concentration in pregnancy is not a reliable guide to the presence or absence of true iron-deficiency anaemia. Tysoe and Lowenstein (1950) found it impossible, without knowing the blood volume, to predict haemoglobin concentration, red cell count or packed cell volume in a given patient, and Lund (1951) also found that the plasma volume increased independently of the mass of haemoglobin by amounts varying from 14 to 121 per cent. of the volume before pregnancy. He described one woman whose haemoglobin concentration fell to about 9·5 g. per 100 ml. while she was taking iron by mouth; the increase of 49 per cent. in her total haemoglobin was masked by an increase of 94 per cent. in plasma volume. Roscoe and Donaldson (1946) showed that by the third trimester there was little or no correlation between the total amount of haemoglobin and its concentration in the blood. The correlation coefficient was 0·145 (S.E. $\pm$ 0·233) and that in non-pregnant women was 0·843 (S.E. $\pm$ 0·127). Yet anaemia in pregnancy is defined by all textbooks in terms of haemoglobin concentration. Eastman (1950), for example, says " . . . the diagnosis of anaemia in pregnant women is not made unless the haemoglobin is less than 10·0 grams (about 70 per cent.), the red cell count less than 3·5 million or the haematocrit reading less than 30 per cent. ", and Brews (1953) states that " Haemoglobin levels of 70 to 80 per cent. are regarded as doubtful anaemia and levels below 70 per cent. as definite anaemia ".

The assessment of iron stores has been suggested as a method for detecting deficiency of iron. Davidson and Jennison (1952) say that " it is probable that ordinary hypochromic anaemia only develops after exhaustion of the iron stores . . . " and Hutchison (1953) goes so far as to say that " if stainable iron were present in the marrow the anaemia would not be improved by the administration of iron ", but Pratt and Johnson (1954) found some iron in marrow even when haemoglobin was low in both pregnant and non-pregnant subjects. Marrow biopsies for estimation of iron, which would be difficult and on a large scale probably undesirable, are not likely to provide a simple indication of deficiency of iron.

In anaemia due only to iron deficiency the bone marrow is normoblastic, but deficiency can occur in association with megaloblastic anaemia. Scott and Govan (1952) suggest that the two conditions do not form distinct entities, but shade into one another; megaloblastic changes occur as the anaemia increases in severity and the capacity to respond to iron is then lost.

The mean cell haemoglobin concentration, and possibly the mean cell volume, appear to be the only reasonably accessible laboratory criteria of iron deficiency in pregnancy. The diagnosis offers an opportunity for the exercise of clinical judgement.

Incidence

The incidence of iron deficiency causing anaemia in pregnancy is not anywhere known, because no survey has been attempted which differentiated the low haemoglobin concentration of anaemia from that of simple haemodilution. The many published series which give the distribution of haemoglobin concentration among pregnant women can be interpreted only on the broadest epidemiological basis. Because of differences in technique of blood sampling and of estimating and recording haemoglobin, and because the stage of pregnancy at which the samples were taken and the method by which women were selected are seldom stated, published surveys are rarely comparable and there would be little profit in listing them. In this country, the Medical Research Council's survey in 1943 (Medical Research Council, 1945) found about 5 per cent. of women with haemoglobin below 10·4 g. per 100 ml. (70 per cent. Haldane) in the first half of pregnancy, and Benstead and Theobald (1952) found that 6·5 per cent. of 2000 Bradford women had less than 10 g. per 100 ml. before 16 weeks. In Glasgow in 1946–47, Scott and Govan (1949) found that 17·6 per cent. of 4595 women had haemoglobin concentrations below 10·4 g. per cent. at their first visit to the antenatal clinic. But in Aberdeen in 1954–55 only 2·4 per cent. of 3841 women, of whom 55 per cent. attended before the 16th week, had a haemoglobin concentration below 10·4 g. per 100 ml. in venous blood taken at the first antenatal examination (Turnbull, 1956).

Elsewhere low concentrations of haemoglobin in pregnant women are reported to occur much more frequently. In Dublin, Doyle and McGrath (1954) found 31·4 per cent. of 1000 " unselected " women attending the Coombe Hospital to have 10 g. haemoglobin per cent. or less, and Lillie *et al.* (1954) found 23·8 per cent. with less than 10 g. at their first visit to the antenatal clinic at the Rotunda Hospital. Wesselhöft (1950) said that 46·9 per cent. of 2970 pregnant women in Hamburg in 1947–48 had less than 10·4 g. haemoglobin. By contrast, Walsh *et al.* (1953) reported that only 4 per cent. of Sydney women had 10 g. haemoglobin per cent. or less at any stage of pregnancy. Although these figures allow rough comparison, no conclusion can be drawn about the incidence of iron deficiency. There is considerable scope for research into iron deficiency in pregnancy on a population basis, with a more meaningful criterion such as mean cell haemoglobin concentration.

Etiology

It is usual for the low haemoglobin in the surveys quoted to be attributed in large part to deficiency of iron in the diet, or to a generally poor diet, but any supporting evidence is at best indirect. Many of the low haemoglobin values in these series form the lower end of the range normal in pregnancy and are not due to deficiency of any sort. In Magee and Milligan's (1951) series of Manchester women, the 5·2 per cent. who were graded as nutritionally " poor " or " fair " by the criteria of the Ministry of Health had a slightly, but not significantly, lower average concentration of haemoglobin than those of better nutritional status. In Doyle and McGrath's (1954) Dublin series the general social and economic circumstances, including the diets, of 504 women were assessed by an almoner ; where conditions were good, 30 per cent. were " anaemic ", and of the 27 women whose circumstances were poor, 22 were anaemic. From similar investigations, also in Dublin, Lillie *et al.* (1954) attributed low haemoglobin levels to defective diet and related seasonal variations in incidence to seasonal changes in diet. In the 6 months from December to May, the percentage of patients with less than 9 g. haemoglobin per 100 ml. ranged from 10 to 14, average 11·6 ; from June to November the range was from 4 to 9 per cent., the mean 6·6. The high incidence of anaemia in pregnancy in post-war Hamburg was attributed by Wesselhöft (1950) to poor diet.

A rough comparison can be made between recent data (Turnbull, 1956) and those of Fullerton (1936), both for Aberdeen ; exact comparison is not possible. From the recent data, all booked hospital patients from Social Classes IV and V were taken as the group most nearly comparable with Fullerton's " representative cross-section of the poor classes in Aberdeen ", but the later investigation used venous blood and the earlier capillary blood from finger pricks. The average haemoglobin concentration of the women in 1955 was about 1 g. per 100 ml. higher at all stages of pregnancy than that from the group investigated 20 years earlier. A proportion of this difference almost certainly results from the difference in methods of blood sampling (see p. 867), but the real difference, possibly of the order of 0·5 g., may be attributable to general improvement in nutrition between the two investigations.

The relationship between parity and anaemia has been discussed already, and it was suggested that the slightly lower haemoglobin concentration found by some in pregnancies after the first might be explained by greater dilution of blood. The only published study of a sufficient number of pregnancies of high parity is from Dublin (Doyle and McGrath, 1954). The proportion of women with haemoglobin concentrations of 10 g. per 100 ml. or less was about 30 per cent. for the first 5 pregnancies and then rose to about 40 per cent. for further pregnancies, which might suggest depletion of stores of iron.

Apart from deficiency of iron, several other contributory causes have been suggested. Strauss and Castle (1932) thought that reduced gastric secretion in pregnancy was likely to prejudice the absorption of iron, and Hamilton *et al.* (1953) were able to improve the clinical response to iron by giving dilute hydrochloric acid with it. On the other hand, Grace *et al.* (1954) have confirmed that absorption of iron is not necessarily related to gastric acidity, and most recent experiments with labelled iron show that absorption is always improved in pregnancy (Hahn *et al.*, 1951 ; Balfour *et al.*, 1942). Other evidence suggests that, in a few women, there may be a temporary breakdown in iron metabolism. Klopper and Ventura (1951), for example, described 5 women, out of 1804 studied, who had severe normocytic anaemia with reasonably high serum iron, in whom they believed there was a block in the utilisation of iron, and Scott and Govan (1951) have described a small proportion of anaemic pregnant women who responded slowly or poorly to intravenous iron, though women with puerperal anaemia always responded quickly. Scott (1956), on the basis of two subjects, attributes delayed response to intramuscular iron to haemodilution which temporarily masks haemopoiesis.

Clinical Features

The clinical features of hypochromic anaemia in pregnancy are similar to those of any hypochromic anaemia and need not be described here ; as in

other anaemias, pallor of the skin and mucous membranes is without significance. It is significant that, in pregnancy, apparently severe anaemia may be symptomless. For example, a third of the women found by Lillie *et al.* (1954) to have less than 10 g. haemoglobin per 100 ml. had no symptom, and symptoms were not always found until the haemoglobin concentrations were as low as 6 g. per 100 ml., a level which is unlikely to be physiological.

Treatment

Treatment with iron in pregnancy is probably seldom necessary. It will be clear from what has been said earlier in this review that a "low" haemoglobin without morphological evidence of deficiency requires no treatment. If a woman has had a low intake of iron for a long time, or has lost iron by bleeding, so that her stores are insufficient to supply the demands of the foetus and her own need for extra haemoglobin, her requirements are not likely to be met by ordinary diet.

To give salts of iron by mouth is the usual treatment. There is a large literature reporting the effects of many preparations of iron alone or in combination with other haematinics, but there are seldom comparable data from which relative efficiencies may be estimated. All seem to be effective in a high proportion of patients, and in a recent experimental comparison, not during pregnancy, O'Sullivan *et al.* (1955) found no difference in efficiency between ferrous sulphate, ferrous gluconate and ferrous succinate. It is generally agreed that ferric salts are much less effective than ferrous. Cope *et al.* (1956) have shown that ferrous succinate in pregnancy is as effective by mouth as about one-third of the amount of iron in preparations given parenterally. Copper, manganese and molybdenum added to iron have not been shown to increase the efficiency with which it is used.

Hahn *et al.* (1951), in a large study with ^{59}Fe in ferrous sulphate, showed that the mean quantity of iron absorbed from a given amount in "normal healthy . . . non-anaemic" women increased as pregnancy advanced, but above a certain level extra intake had only a slight effect on the amount absorbed. For example, after the 25th week of pregnancy about 5 mg. was absorbed from 20 mg., but with larger amounts the absorption increased relatively little; only about 6 mg. was absorbed from 40 mg. and 9·5 mg. from 120 mg. From these figures and on the assumption that such rates of absorption are maintained, it can be calculated that, in the second half of pregnancy, 3 standard tablets daily, each containing 55 to 60 mg. iron, would supply about 15 mg. iron to the body each day, 105 mg. in a week, so the total requirement of pregnancy would be provided in six weeks. More would probably be absorbed in true iron deficiency. In comparison, the doses of iron used in most of the reported series, varying from about 165 to 330 mg. daily, are large and seem to have been derived quite arbitrarily.

The common complications of oral iron medication are nausea and vomiting, and they may be a handicap to its use, but no clear picture can be formed from the literature to show whether the incidence or severity of these side effects is related to the amount given. Lund (1951), who gave 1200 mg. of molybdenised ferrous sulphate (240 mg. iron) daily to 75 women, had to stop treatment because of digestive disturbance in only one. But Lillie *et al.* (1954), who gave ferrous sulphate in doses of 1200 mg. daily, found that half the women could not tolerate it, and, in the series of Fisher and Biggs (1955), about the same proportion of women taking half that quantity of ferrous sulphate "complained of digestive disturbances". Such reports raise doubt about the validity of studies of iron treatment where there were few reactions or none. It may be that the lack of haematological response in some women in most studies may be due to failure to take the iron because of its side effects, not to failure to absorb or use it. Benstead and Theobald (1952), who found that a high proportion of women in their series were intolerant of ferrous sulphate, said "It can be assumed that between 30 and 40 per cent. of all antenatal patients will not, in fact, take these tablets if they are routinely prescribed in the antenatal department". It is widely agreed that, of all the ferrous salts, the sulphate is least well tolerated. Lund (1951) claimed that its side effects were less when it was given with molybdenum, and this was confirmed by Benstead and Theobald, who found 86 per cent. of women able to tolerate the combination, compared with between 60 and 70 per cent. of those who took the ordinary ferrous sulphate tablet.

Fisher and Biggs (1955) claimed that a preparation of ferrous sulphate with ascorbic acid was tolerated better than the routine ferrous sulphate tablet, but in the combined tablet the dose of ferrous sulphate was reduced by a third, so that the beneficial effect may not have been due to the ascorbic acid. Other ferrous salts are much better tolerated. Ferrous gluconate, in particular, causes considerably fewer and less severe side effects (Jones, 1953; Lillie *et al.*, 1954).

The possible value of hydrochloric acid given with the iron has already been discussed (p. 864). Failure to show the usual haematological response to oral iron has been reported for from 8 to 22 per cent. of women in many of the published series (Govan and Scott, 1949; Lund, 1951; Hamilton *et al.*, 1953; Fisher and Biggs, 1955; Edgar and Rice, 1956). They usually, but not always,

respond well to intravenous or intramuscular iron. Scott and Govan (1951) reported that of 13 pregnant women with anaemia refractory to oral iron, 11 responded rapidly to intravenous iron, but the other 2 had a "delayed" response. The result is not worse than the response shown by 78 other pregnant women with anaemia, of whom 26 showed a delayed or poor response to intravenous iron. Intramuscular iron has been used successfully by Jennison and Ellis (1954), Scott (1956) and Cope *et al.* (1956).

It has been calculated (Heath *et al.*, 1932) that the haemoglobin should be raised by 0·64 g. per 100 ml. by 100 mg. iron. In pregnancy the mean rise is much less than that. Klopper and Ventura (1951) found the haemoglobin to rise by only 0·44 g. per 100 ml. for each 100 mg. of iron, and Scott and Govan (1951 ; 1954) found a mean rise of only 0·3 g. per 100 ml. for each 100 mg. of iron given by either intravenous or intramuscular injection. Scott (1956) reports that " utilisation " falls from 0·309 g. to 0·173 g. as bodyweight rises from 100 to over 160 lb. The word " utilisation " has no meaning, since difference in weight may be merely difference in retention of water. Differences in response are presumed by Ventura and Klopper to be due to passage of iron to the foetus, but one would in any case expect a smaller rise in *percentage* of haemoglobin when the plasma volume is raised as it is in pregnancy. In one pregnant woman with severe anaemia the whole of 18 mg. of ^{59}Fe given intravenously was used for maternal haemoglobin (Dubach *et al.*, 1955).

The side reactions associated with parenteral administration of iron are apparently not altered by pregnancy. They will not be discussed here. The dose given appears to be generally quite arbitrary, but large, varying from 900 mg. intravenously (Hamilton *et al.*, 1953) to 2000 mg. by intramuscular injection (Scott and Govan, 1954). Jennison and Ellis (1954) gave iron by intramuscular injection in anaemia of pregnancy only when there was no demonstrable iron in the marrow. On the assumption that " 250 mg. would increase the haemoglobin of non-pregnant patients by 10 per cent ", they calculated their dose as

$$\frac{100 - \text{observed Hb per cent.}}{10} \times 250 + 500 \text{ mg.}$$

to allow for " depletion of iron, increased blood volume, and the demands of the foetus ".

There seems to be little doubt that iron given parenterally is useful both where iron by mouth is ineffective or not tolerated and where iron deficiency must be corrected quickly, but it has a drawback ; there is considerable evidence that the body normally regulates its uptake of iron according to its requirements, as it must when it has no mechanism for excretion, and the same is true even in pregnancy, although the temporary diversion of stored iron to extra haemoglobin probably causes the real requirement to be overestimated. When iron is given parenterally this discriminating mechanism is by-passed and excess of iron must then be immobilised as haemosiderin. It is important, therefore, that the dose should be calculated with some regard to the changed circumstances of pregnancy. There is no need to fill the iron stores when they will be replenished after delivery ; and there is no evidence that an unphysiological procedure such as raising the haemoglobin during pregnancy to 14·8 g. per 100 ml. is beneficial in any way.

Summary

In normal pregnancy the plasma volume rises, on the average, by about 40 per cent. and the red cell mass by about 17 per cent. The result is reduction of the red cell count to about 80 or 85 per cent. of the non-pregnant ; the haemoglobin concentration and the packed cell volume show a parallel decrease. Minimum levels are usually reached during the third trimester. There is no qualitative alteration of the red cell ; the mean cell haemoglobin concentration remains within normal limits.

The fall in haemoglobin concentration during pregnancy is often interpreted as an index of iron deficiency because it can be reduced or prevented by giving additional iron, but iron in large doses appears to be a specific stimulus to blood formation even in healthy non-pregnant persons. There are other analogies between the blood in pregnancy and in iron-deficiency anaemia : the serum iron is lower and the iron-binding capacity is raised ; the serum copper is higher and there is an increase in free protoporphyrin. None of these is a specific sign of iron deficiency.

There are good theoretical reasons why the rise in plasma volume is proportionately greater than the increase in red cells. The red cell mass increases only in response to a demand for increased oxygen transport, and the mean increase of 17 per cent. with the 20 per cent. rise in velocity of blood flow more than covers the need for oxygen. This favourable balance is confirmed by a decrease in the mother's arterio-venous oxygen difference during pregnancy. Plasma volume is controlled by a different mechanism ; extra plasma is required both to carry the extra red cells and fill the increased vascular space and to dissipate foetal heat.

No advantage has been demonstrated from raising the haemoglobin level in normal pregnancy and there may be dangers. The fall in the concentration of red cells results in a fall in blood viscosity and this makes a substantial saving in

the work of the heart, contributing to the maintenance of normal blood pressure as the cardiac output rises.

Since iron absorption is proportionately much increased during pregnancy and large quantities are absorbed from medicinal doses, there is a danger of excessive storage of iron.

The very wide individual variation in the extent of haemodilution makes it impossible to give an arbitrary lower value for haemoglobin concentration in normal pregnancy. Nevertheless, all published surveys of the incidence of anaemia in pregnancy rely on haemoglobin concentration as their main criterion. There has been no survey of anaemia in pregnancy on a more meaningful basis such as mean cell haemoglobin concentration. The diagnosis offers an opportunity for the exercise of clinical judgement.

A high incidence of "low" haemoglobin levels has been taken as evidence of poor nutrition, but, in the United Kingdom at least, the average diet provides more than enough iron for the extra requirements of pregnancy.

The treatment of iron deficiency anaemia in pregnancy is discussed.

Note on Technique

It is uncommon, in published papers, for the technique of blood sampling and of haemoglobin estimation to be described in detail, and yet results from different investigations cannot be adequately compared without full knowledge of the procedures used. The technical pitfalls of haemoglobinometry have frequently been stressed; readings vary between instruments and observer errors can be large. Even if one assumes that the technique of examining the blood has always been accurate, the procedure used for obtaining the blood can introduce gross errors, many of which have been reviewed by Walsh *et al.* (1953). There are seasonal and diurnal variations in venous haemoglobin concentration. Walsh *et al.* found the mean haemoglobin level in Sydney women in summer to be about 0·5 g. per 100 ml. below the winter mean; in 34 women the mean haemoglobin concentration at 9 a.m. was 0·34 g. per 100 ml. higher than the mean at 3 p.m., and the difference in some women was as high as 1 g. per 100 ml. between morning and afternoon readings. Physical exercise can cause a transitory haemoconcentration and lying down can cause a fall in haemoglobin level in peripheral blood. A tourniquet round the arm causes a progressive rise in the haemoglobin concentration of blood distal to it which is obvious after half a minute of constriction. Capillary blood from the finger tip has a considerably lower haemoglobin concentration than venous blood in pregnant women; Lund (1951) found an average difference of about 0·5 g. per 100 ml.

It can be appreciated from this summary of the known influences on venous haemoglobin concentration that substantial differences in haemoglobin values between groups of women can be introduced by differences of technique. For example, blood samples obtained by finger prick at an afternoon antenatal clinic are bound to show much lower readings than venous samples taken in the morning from the same women.

1. TECHNIQUE

CHEMICAL

APPARATUS

4010

WOOD, T. **A laboratory electrodialyser and desalter.** *Biochem. J.*, 1956, **62,** 611–613. [Res. Dept., Bovril, Ltd., 148–166 Old St., London, E.C.1.]

4011

STADHOUDERS, J., MULDER, H. and VAN CAPELLEVEEN, A. G. **An automatic fraction collector for chromatographic analysis.** *Nederlands Melk Zuiveltijdschr.*, 1956, **10,** 60–63. [Lab. Dairying, Agric. Univ., Wageningen.] Dutch summary.

The device operates on the constant volume principle and is photo-electrically controlled.

H. G. Bray.

4012

HOTTA, K. and MORISHITA, M. **A Rf scale for paper chromatography.** *Nagoya J. Med. Sci.*, 1955, **18,** 183–185. [Dept. Biochem., Sch. Med., Nagoya Univ.]

The R_F scale consists of a plastic triangle with a right angle at the base and the sides forming the apex graduated into 100 equal divisions and joined by lines. If the origin spot of the chromatogram is placed at the beginning of the scale at the apex and the solvent front on the base, the line passing through the unknown spot seen through the transparent plastic gives the R_F value.—A. Hepburn.

4013

BANGHAM, D. R. **A collimated windowless Geiger counter for scanning chromatograms.** *Biochem. J.*, 1956, **62,** 550–551. [Nat. Inst. Med. Res., Mill Hill, London, N.W.7.]

4014

BANGHAM, D. R. **A simple helium-ethanol flow counter for monitoring chromatograph-column effluents containing weak β-emitting isotopes.** *Biochem. J.*, 1956, **62,** 552–553. [Nat. Inst. Med. Res., Mill Hill, London, N.W.7.]

4015

MIDKIFF, V. C. **Three devices which aid the crude fiber determination.** *J. Assoc. Off. Agric. Chem.*, 1956, **39,** 529–531. [Kentucky Agric. Exp. Stat., Lexington.]

Helpful additions to the apparatus used in the method of Midkiff and Shrader (Abst. 4, Vol. 20) are described.—A. Hepburn.

4016

HEIN, R. E., CLEGG, R. E., CLARK, T. J. and MCFARLAND, R. H. **Electrophoresis cells modified for determination of labeled protein fractions.** *Anal. Chem.*, 1956, **28,** 544–545. [Kansas State Coll., Manhattan.]

The ascending arm of the centre cell of the Tiselius apparatus is modified to permit measurement of the radio-activity associated with the protein front. The modification does not affect other observations usually required, *e.g.*, mobilities, electrophoretic patterns.—H. G. Bray.

4017

RAPPAPORT, F., EICHHORN, F. and NUTMAN, M. **An apparatus for microdetermination of CO_2 in plasma.** *J. Clin. Pathol.*, 1956, **9,** 166–170. [Beilinson Hosp., Petach Tiqua, Israel.]

A modified Van Slyke apparatus is described, for samples of from 0·05 to 0·1 ml. plasma. The results obtained can be read directly from Van Slyke's nomogram.—H. G. Bray.

4018

BOESEN, E. and LOUD, P. A. **A preliminary communication on a conductrimetric screening test for electrolytes.** *J. Clin. Pathol.*, 1956, **9,** 173–175. [Central Lab., Portsmouth.]

An apparatus for measuring the conductivity of plasma is described. The average normal range of values for plasma electrolytes found from 118 samples was from 290 to 310 m. equiv. per litre. The use of the test in the study of electrolyte balance is suggested.—H. G. Bray.

See also Absts. 4047, 4073.

ANALYTICAL METHODS

General

4019

CLAYTON, R. A. **Chamber size and R_f values of amino acids.** *Anal. Chem.*, 1956, **28,** 904–906. [Dept. Biochem., Sch. Med., George Washington Univ., Washington 5, D.C.]

The term " critical volume " is suggested for the volume of solvent necessary to saturate a specific chamber under given conditions. Volumes of solvent above this value give constant and minimum R_F values: volumes below the critical volume give constant maximum values. It is suggested that greater standardisation of R_F values would result if volumes of chamber and solvent were reported in publications.—H. G. Bray.

4020

POTTERAT, M. Une nouvelle technique de chromatographie sur papier. [**New technique for chromatography on paper.**] *Mitt. Geb. Lebensmittel. Hyg.*, 1956, **47**, 66–71. [Serv. Féd. Hyg. Pub., Berne.] German and English summaries.

A procedure is described by which 8 spots can be run on the same circular chromatogram (cf. Matthias, *Naturwissenschaften*, 1954, **41**, 17).

H. G. Bray.

4021

GORBACH, G. and DEMMEL, H. Beiträge zur quantitativen "Test-tube"-Papierchromatographie. [**Quantitative "test-tube" paper chromatography.**] *Mikrochim. Acta*, 1956, No. 7–8, 1264–1276. [Inst. Biochem. Technol., Tech. Hochsch., Graz.]

A procedure for small-scale quantitative paper chromatography is described.—H. G. Bray.

4022

AZERAD, E., LEWIN, J. and GHATA, J. L'électrophorèse sur papier. Étude critique. [**Electrophoresis on paper. Critical study.**] *Presse méd.*, 1956, **64**, 717–719. [Lab. Nutrit., Hôp. Beaujon, Clichy.]

4023

AFONSO, E. and AFONSO, S. Uma nova técnica de microelectroforese. [**New technique for microelectrophoresis.**] *An. Inst. Med. trop.*, 1955, **12**, 757–764. [Lab. Anál., Estado India.] French and English summaries.

4024

HIMES, M. and MORIBER, L. **A triple stain for deoxyribonucleic acid, polysaccharides and proteins.** *Stain Technol.*, 1956, **31**, 67–70. [Dept. Zool., Columbia Univ., New York.]

The sequence of stains is Feulgen with azure A-Schiff reagent, periodic acid Schiff with basic fuchsin-Schiff reagent, and 0·02 per cent. naphthol yellow S in 1 per cent. acetic acid. Nuclei stain blue to green, polysaccharides red and proteins yellow. The procedure was found to be specially useful for stomach, intestine, kidney, thyroid and plant root tips.—H. G. Bray.

Carbohydrate Constituents

4025

LORING, H. S., LEVY, L. W. and MOSS, L. K. **Detection and paper chromatography of sugars and sugar phosphates in picric acid system.** *Anal. Chem.*, 1956, **28**, 539–540. [Dept. Chem., Stanford Univ., Calif.]

The solvent mixture consists of picric acid, 4 g., dissolved in *tert.*-butanol, 80 ml., and water, 20 ml. The papers are dried in air, sprayed with ethanolic NaOH and heated at 85° C. for 7 to 10 min.: sugars and sugar phosphates give reddish brown spots. R_F values are given for 14 sugars and 6 sugar phosphates.—H. G. Bray.

4026

GORDON, H. T., THORNBURG, W. and WERUM, L. N. **Rapid paper chromatography of carbohydrates and related compounds.** *Anal. Chem.*, 1956, **28**, 849–855. [Dept. Entomol., Univ. California, Berkeley 4.]

An account is given of an ascending procedure for the rapid separation and identification of carbohydrates in biological fluids without previous desalting or purification. Interference by inorganic salts is eliminated by the use of pyridinium sulphate. The developing solvent is *iso*propanyl : pyridine : acetic acid : water (8 : 8 : 1 : 4). R_F values are given for about 70 carbohydrates and derivatives, as well as their reactions with 4 spray reagents.—H. G. Bray.

4027

WOLFROM, M. L. and MILLER, J. B. **Detection of carbohydrates on paper chromatograms.** *Anal. Chem.*, 1956, **28**, 1037. [Dept. Chem., Ohio State Univ., Columbus 10.]

The dry chromatogram is sprayed with 1 per cent. sodium metaperiodate and 3 to 4 min. later with 1 per cent. aqueous potassium permanganate. After 5 min. excess permanganate is washed away and the chromatogram is dried and sprayed with a benzidine reagent (benzidine 1 g., trichloroacetic acid 8 g., anhydrous acetic acid 20 ml. and absolute ethanol 160 ml.). Carbohydrates are revealed as dark blue spots against a light blue background.—H. G. Bray.

4028

MORENO CALVO, J. Cromatografía de glúcidos sobre papel. [**Chromatography of sugars on paper.**] 1. Resultados con el sistema acetato de etilo-piridina-agua. [**1. Results with ethyl acetate, pyridine and water.**] 2. Aplicación a productos alimenticios y a otras sustancias naturales. [**2. Application to food products and other natural substances.**] *An. Bromatol.*, 1955, **7**, 95–105; 107–115. [Inst. Español Fisiol. Bioquím.]

1. The sugars were in 1 per cent. solution. Chromatography was on strips of Whatman No. 1 paper, 4 by 41 cm. The solvent was a 2 : 1 : 2 mixture of ethyl acetate, pyridine and distilled water. The developer was prepared by dissolving 930 mg. aniline and 1·6 g. phthalic acid in 10 ml. distilled water saturated with butanol. An illustration is given of a chromatogram showing arabinose, glucose, mannose, fructose, sucrose,

lactose and raffinose. R_F values are tabulated. Maximum sensitivity was obtained with 1·6 μl. of 1 per cent. solutions.

2. Sugars were identified in cow's milk, coffee with milk, sherry and fruit juices. Pure coffee was free from sugar. Inorganic ions present did not interfere.—D. Duncan.

4029

TING, S. V. **Rapid colorimetric methods for simultaneous determination of total reducing sugars and fructose in citrus juices.** *J. Agric. Food Chem.*, 1956, **4**, 263–266. [Florida Citrus Exp. Stat., Lake Alfred.]

The sugars are oxidised with ferricyanide and the ferrocyanide formed is converted to a blue derivative by an arsenomolybdate reagent and estimated colorimetrically. At 100° C. glucose and fructose are oxidised to equal extents: at 55° C. fructose is completely oxidised, but only 1/8 to 1/9 of the glucose, so that differential analysis of the sugars is possible.—H. G. Bray.

4030

SZUMSKA, M. Porównanie środków odbiałczających stosowanych przy ilościowyn oznaczaniu cukrów. [**Comparison of protein precipitants used in the quantitative estimation of sugars.**] *Rocz. Państwowego Zakł. Hig.*, 1956, **7**, 185–190. Russian and English summaries.

The properties of basic lead acetate plus NaH_2PO_4 or Na_2SO_4 and of Carrez's reagents (see Hadorn and Jungkunz, Abst. 4571, Vol. 20) used for protein precipitation in the estimation of sugars in honey, marmalade and wine are discussed. It was concluded that Carrez's reagents gave the best results and basic lead acetate plus Na_2SO_4 produced the greatest adsorption of sugar on the precipitate. (From English summary.)—A. Hepburn.

4031

HADORN, H. and BIEFER, K. W. Über den Einfluss von Aminosäuren auf die Zuckerbestimmung speziell nach der Methode von Potterat und Eschmann sowie nach Hadorn und von Fellenberg. [**Effect of amino acids on estimation of sugar, especially by the methods of Potterat and Eschmann and of Hadorn and von Fellenberg.**] *Mitt. Geb. Lebensmittel. Hyg.*, 1956, **47**, 4–15. [Lab. VSK, Basle.] French and English summaries.

Some amino acids increase the reducing power of sugars and favour the formation of colloidal cuprous oxide.—H. G. Bray.

4032

GRIMBLEBY, F. H. **The determination of lactose in milk.** *J. Dairy Res.*, 1956, **23**, 229–237. [Dept. Agric. Chem., Univ. Reading.]

Protein-free milk serum was made by adding 5 ml. of a zinc acetate and phosphotungstic acid reagent (25 g. and 12·5 g., respectively, 20 ml. glacial acetic acid and water to 100 ml.) to 40 ml. milk, diluting to 50 ml. and filtering. The lactose in this solution of p_H 4·6 was estimated by polarimetry, with corrections for the percentage and specific volumes of the precipitated protein and fat. After experiments with different protein-precipitating agents at different p_H values it is suggested that any errors introduced by conditions affecting the lactose content of the serum, namely, (1) incomplete precipitation of protein, (2) formation of lactose-protein complexes and (3) degree of hydration of the protein coagulum, were reduced to a minimum by this method.—A. Hepburn.

4033

KRAJČINOVIĆ, M. and DJUKIĆ-JOVANOVIĆ, J. Über den Einfluss der Salzsäure auf den hydrolytischen Abbau von Stärke und Stärkerohstoffen im Zusammenhang mit der quantitativen Bestimmung der Stärke. [**Effect of hydrochloric acid on the hydrolytic decomposition of starch and materials containing starch, with reference to the quantitative estimation of starch.**] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1956, **103**, 350–355. [Tehnički Fak., Zagreb.]

The effect of different concentrations of HCl on the hydrolysis of maize, maize starch and residues was studied by estimating reducing values and dextrin content. The results obtained did not agree with those obtained with standard polarimetric procedures.—H. G. Bray.

4034

DOUGALL, H. W. **Crude fibre: its determination and its place in the analysis of animal feeding-stuffs.** *E. African Agric. J.*, 1956, **21**, 225–229. [Grassland Res. Stat., Dept. Agric., Kenya.]

The work of Voelcker, and of Henneberg and Stohman, leading to establishment of the Weende method for the estimation of crude fibre is described. The present modifications of the method by other workers and its shortcomings are discussed.

T. D. Bell.

4035

ROADHOUSE, F. E. and MACDOUGALL, D. **A study of the nature of plant lignin by means of alkaline nitrobenzene oxidation.** *Biochem. J.*, 1956, **63**, 33–39. [Ontario Agric. Coll., Guelph.]

4036

GYERMEK, L. and FEKETE, GY. **Studies with a simple method of liver glycogen estimation.** *Acta physiol. hung.*, 1955, **8**, 259–267. [Pharmacol. Dept., Pharmaco-Indust. Res. Inst., Budapest.] Russian summary.

Liver homogenate is deproteinised with trichloroacetic acid, alcohol is added to the filtrate and the turbidity is measured photometrically. The accuracy of the method is claimed to be comparable with that of hydrolytic methods and greater than that of colorimetric methods.—H. G. Bray.

See also Abst. 4134.

Nitrogenous Constituents

4037

SHAH, G. D., PANSARE, V. S. and MULAY, V. N. **A modified micro-Dumas method for rapid determination of nitrogen.** *Mikrochim. Acta*, 1956, No. 7–8, 1140–1143. [Nat. Chem. Lab., Poona, India.]

A procedure for serial estimations is described in which the copper oxide in the tube need not be changed for each analysis, nor heating discontinued.

H. G. Bray.

4038

BELCHER, R. and BHATTY, M. K. **The elimination of the distillation procedure in the Kjeldahl method.** *Mikrochim. Acta*, 1956, No. 7–8, 1183–1186. [Chem. Dept., Univ. Birmingham.]

After digestion, with mercury as catalyst, the solution is diluted, neutralised and treated with KBr. Excess sodium hypochlorite is added to oxidise ammonia, then excess arsenious oxide. The excess of the latter is estimated by titration with hypochlorite, with tartrazine as indicator. This procedure is not applicable when preliminary reduction is necessary.—H. G. Bray.

4039

MONTY, K. J., MORRISON, M., ALLING, E. and STOTZ, E. **Electrophoresis of cationic proteins on filter paper.** *J. Biol. Chem.*, 1956, **220,** 295–302. [Dept. Biochem., Sch. Med. Dent., Univ. Rochester, N.Y.]

Adsorption of cationic proteins on filter paper results in tailing, so that mobility depends on the concentration of protein. This can be prevented by impregnating the paper with a cation detergent.

H. G. Bray.

4040

SCHOBER, R. and HETZEL, H. Zur Trennung von Milchproteinen durch Säulenchromatographie. **[Separation of milk proteins by chromatography on columns.]** *Milchwissenschaft*, 1956, **11,** 63–65. [Staatl. Milchwirtsch. Lehr.-Forschungsanst., Wangen, Allgäu.] English and French summaries.

The proteins are adsorbed on alumina columns at *p*H 4·2 and fractionally eluted with phosphate buffers of different *p*H and ionic strength. The proteins in the eluates are estimated by the biuret reaction and examined by paper electrophoresis.

H. G. Bray.

4041

SCHOBER, R. and HETZEL, H. F. Über eine einfache, kolorimetrische Bestimmung von Milchproteinen. **[Simple colorimetric estimation of milk proteins.]** *Milchwissenschaft*, 1956, **11,** 123–126. [Staatl. Milchwirtsch. Lehr.-Forschungsanst., Wangen, Allgäu.]

Milk is treated with a solution of Amidoschwarz 10B at *p*H 2·8 and centrifuged. The dye not adsorbed by the proteins and remaining in the supernatant fluid is measured spectrophotometrically at 578 mμ. The method is standardised against the Kjeldahl method and gives results comparable with those of formol titration.—H. G. Bray.

4042

ROLAND, F. Die quantitative Bestimmung der Hüllenieweiss-substanz der Milchfettkügelchen. **[Quantitative estimation of the protein substance of the membrane of milk fat globules.]** *Milchwissenschaft*, 1956, **11,** 85–87. [Lab. Milchverwertungs-Genossensch., Herford.] English, Spanish and French summaries.

A method based on ascertainment of the partition of nitrogen between the layers of centrifuged milk is described. It is calculated that there is about 1 g. protein per 100 g. milk fat.—H. G. Bray.

4043

PARSONS, T. R. and BAKER, B. E. **Studies on protein hydrolysis. 3. The preparation and analysis of sulphurous acid hydrolysates of casein.** *J. Sci. Food Agric.*, 1956, **7,** 261–265. [Dept. Chem., Fac. Agric., Macdonald Coll., McGill Univ., Que.]

For part 2 see Abst. 1607, Vol. 25.

3. Casein was hydrolysed by heating for 24 hr. at 100° C. with *N* HCl saturated with SO_2. SO_2 was removed by evaporation under reduced pressure and HCl by passage through a column of anion-exchange resin. The hydrolysate contained half the tryptophan of casein, less total N, and relatively less acid amino acids and more basic amino acids. Rat feeding trials showed that the hydrolysate was not inferior to casein or a commercial enzymic digest of casein.—A. Hepburn.

4044

UDY, D. C. **Estimation of protein in wheat and flour by ion-binding.** *Cereal Chem.*, 1956, **33,** 190–197. [Field Crops Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Pullman, Wash.]

The method depends on the binding of the dye Orange G by wheat proteins at *p*H 2·2 to form an insoluble complex. The samples are treated with an excess of a buffered solution of the dye and the excess is measured colorimetrically. Starch and bran bind significant amounts of dye.

H. G. Bray.

4045

BUGYI, B. Vereinfachung der refraktometrischen Bestimmung des Bluteiweissgehaltes. [**Simplification of the refractometric estimation of blood protein.**] *Deutsch. Ztschr. Verdauungs- u. Stoffwechselkr.*, 1956, **16,** 120–121. [Komitatskrankenhaus, Szolnok, Hungary.]

A nomogram is given relating refractive index and temperature to protein content.—H. G. Bray.

4046

SMITHIES, O. and POULIK, M. D. **Two-dimensional electrophoresis of serum proteins.** *Nature*, 1956, **177,** 1033. [Connaught Med. Res. Labs.]

The proteins are separated first by electrophoresis on filter paper and then in a starch gel in a direction at right angles to the first. This technique gives information about the distribution of molecular sizes in electrophoretic fractions.

H. G. Bray.

4047

LAURELL, C. B., LAURELL, S. and SKOOG, N. **Buffer composition in paper electrophoresis : considerations on its influence, with special reference to the interaction between small ions and proteins.** *Clin. Chem.*, 1956, **2,** 99–111. [Lab. Clin. Chem., Malmö Hosp., Sweden.]

An apparatus built on the moist-chamber principle is described. The separated fractions were eluted with 0·1 *N* Na_2CO_3 and their absorption was measured at 595 mμ. When small amounts of Ca ions were added the β-lipoprotein fraction of serum was resolved into 2 fractions. The effect of Ca on the mobility of other fractions was studied.

H. G. Bray.

4048

HIRSCH, A. and CATTANEO, C. **The quantitative determination of plasma fibrinogen through the electrophoresis of blood plasma on filter paper.** *Arch. Biochem. Biophys.*, 1956, **61,** 27–37. [Dept. Biol. Chem., Clin. Tisiol., Univ. Rome.]

4049

WYCOFF, H. D. **A microassay for plasma fibrinogen.** *J. Lab. Clin. Med.*, 1956, **47,** 645–648. [Augusta, Ga.]

4050

GOTTSCHALK, A. and ADA, G. L. **The separation and quantitative determination of the component sugars of mucoproteins.** *Biochem. J.*, 1956, **62,** 681–686. [Walter and Eliza Hall Inst. Med. Res., Melbourne, Australia.]

The procedure consists in acid hydrolysis of the mucoprotein, neutralisation and concentration of the hydrolysate, removal of unhydrolysed protein and polypeptides by precipation with ethanol, removal of amino acids and peptides on an ion-exchange resin and identification of amino acids by paper chromatography. The accuracy of the method is $\pm$ 10 per cent.—H. G. Bray.

4051

BALIKOV, B. and CASTELLO, R. A. **Urinary peptides : method for assay.** *Clin. Chem.*, 1956, **2,** 83–90. [Surg. Res. Unit, Brooke Army Med. Centre, Fort Sam Houston, Tex.]

The method depends on application of the biuret reaction to a tungstic acid filtrate of urine treated with Permutit. The value, as glutathione, for normal subjects was found to be from 1·1 to 4·7 g. per 24 hr.—H. G. Bray.

4052

CHERKIN, A., WOLKOWITZ, H. and DUNN, M. S. **Modified ultraviolet spectrophotometric micromethod for determination of amino acids and peptides as copper complexes.** *Anal. Chem.*, 1956, **28,** 895–896. [Chem. Lab., Univ. California, Los Angeles.]

A simplification of the method of Spies (Abst. 1516, Vol. 22) is described.—H. G. Bray.

4053

BECK, M. T. and ÉBREY, P. **Interaction of substances during the process of paper chromatography.** *Biochim. biophys. Acta*, 1956, **20,** 393. [Inst. Inorg. Anal. Chem., Dept. Paediat., Univ. Szeged, Hungary.]

The interaction of amino acids is considered. The use of complexes of amino acids and metals, which do not interact, is suggested.—H. G. Bray.

4054

SAIFER, A. and ORESKES, I. **Color reaction of amino acids with alloxan, isatin and ninhydrin in circular paper chromatography.** *Anal. Chem.*, 1956, **28,** 501–504. [Isaac Albert Res. Inst., Brooklyn, N.Y.]

R_F values are given for 51 amino acids and related compounds in phenol : water and butanol : acetic acid : water systems, and the colours given on paper by these compounds with ninhydrin, alloxan and isatin. The use of these reagents for distinguishing compounds with similar R_F values is discussed.—H. G. Bray.

4055

BARROLLIER, J., HEILMAN, J. and WATZKE, E. Polychrome Sichtbarmachung von Aminosäuren auf Papierchromatogrammen und Elektropherogrammen. [**Polychromatic reagents for colouring amino acids on paper chromatograms and electropherograms.**]

Hoppe-Seyler's Ztschr., 1956, **304**, 21–25. [Hauptlab. Schering A.G., West Berlin.] English summary.

Two detecting reagents are described, containing isatin and 1 : 2-naphthoquinone - 4 - sulphonic acid, respectively. These give a range of colours with amino acids at different concentrations.

H. G. Bray.

4056

SCHOBER, R., PRINZ, I. and CHRIST, W. Quantitative Mikrobestimmung von Aminosäuren als Dinitrophenyl - Derivate; Anwendung auf Untersuchungen zur Verdaulichkeit von hocherhitzter Milch. [**Quantitative micro-estimation of amino acids as dinitrophenyl derivatives; application to studies of digestibility of milk heated to high temperatures.**] *Milchwissenschaft*, 1956, **11**, 209–210. [Staatl. Milchwirtsch. Lehranst., Wangen, Allgäu.]

The dinitrophenyl amino acids were separated by 2-dimensional paper chromatography, with toluene : ethylene chlorhydrin : pyridine : 0·8 *N* NH_4OH (5 : 3 : 1·5 : 3) followed by phosphate buffer as developing solvents. The separate compounds were cut out, eluted with water and estimated spectrophotometrically. Fifteen amino acids were estimated in the portal blood of dogs which had been given unheated milk and milk heated at 92° to 112° C.—H. G. Bray.

4057

ROSENBERG, H., ENNOR, A. H. and MORRISON, J. F. **The estimation of arginine.** *Biochem. J.*, 1956, **63**, 153–159. [Dept. Biochem., John Curtin Sch. Med. Res., Australian Nat. Univ., Canberra.]

The method depends on the reaction of arginine, diacetyl and α-naphthol in propanol solution to give a red colour and is applicable to protein hydrolysates. Other guanido compounds, *e.g.*, streptomycin, may also be estimated by the procedure described.—H. G. Bray.

4058

GILBOE, D. D. and WILLIAMS, J. N. (Jr.) **Evaluation of the Sakaguchi reaction for quantitative determination of arginine.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91**, 535–536. [Dept. Biochem., Univ. Wisconsin, Madison.]

A procedure is described suitable for the estimation of from 0 to 30 μg. arginine in 5-ml. samples of amino acid mixtures, *e.g.*, protein hydrolysates.

H. G. Bray.

4059

HOLASEK, A., LIEB, H. and MERZ, W. Zur mikroanalytischen Bestimmung von Cystin und Methionin. [**Micro-analytical estimation of cystine and methionine.**] *Mikrochim. Acta*, 1956, No. 7–8, 1216–1218. [Med. Chem. Inst., Univ. Graz.]

The apparatus described is a modification of that of Kuhn *et al.* (Abst. 26, Vol. 9) and can be used for the estimation of sulphydryl, thiomethyl and alkoxy groups.—H. G. Bray.

4060

HALPERN, Y. S. and GROSSOWICZ, N. **Determination of L-glutamic acid by use of L-glutamic acid decarboxylase from *Mycobacterium phlei*.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91**, 370–373. [Dept. Bacteriol., Hebrew Univ.-Hadassah Med. Sch., Jerusalem.]

The preparation used had no decarboxylase activity towards 18 other amino acids, and no glutaminase or glutamo-racemase activity.

H. G. Bray.

MILKS, J. E. and JANES, R. H. **Separation and detection of cyanamide and its derivatives and determination of urea by paper chromatography.** *Anal. Chem.*, 1956, **28**, 846–849.

[North American Cyanamid, Ltd., Welland Plant, Niagara Falls, Ont.]

The solvents used are 1-butanol : ethanol : water (4 : 1 : 1) and methyl ethyl ketone : light petroleum : water (9 : 4 : 3) and the paper is Whatman No. 3 or 3 MM. Detecting reagents are ferricyanide : nitroprusside, ammoniacal silver nitrate, *p*-dimethylaminobenzaldehyde, 2 : 6-dichloro-quinone - chloroimide and 1 : 2 - naphthoquinone - 4 - sodium sulphonate. R_F values and colour reactions are given for a number of cyanamide derivatives. Urea can be estimated with 95 per cent. recovery by elution, the intensity of the colour given with *p*-dimethylaminobenzaldehyde being measured at 420 mμ.—H. G. Bray.

MANGOLD, H. K., LAMP, B. G. and SCHLENK, H. **Indicators for the paper chromatography of lipids.** *J. Amer. Chem. Soc.*, 1955, **77**, 6070–6072. [Univ. Minnesota, Austin.]

Mixtures of microgram quantities of known lipids were subjected to reversed-phase chromatography on Whatman No. 1 paper impregnated with silicone, with acetic acid and water, tetrahydrofuran and water, and chloroform and methanol as solvents. The R_F values are given for a range of saturated and unsaturated fatty alcohols, acids, methyl esters of fatty acids and mono-, di-, and triglycerides. A spray of 1 per cent. α-dextrin in 30 per cent. ethanol followed by exposure to iodine vapour revealed unsaturated alcohols, acids, esters and monoglycerides; the corresponding saturated compounds remained colourless. Di- and triglycerides responded only after hydrolysis into free acids and monoglycerides; this was achieved by spraying the chromatograms with 1 per cent. pancreatin in water and incubating for 24 hr. at 37° C. in a damp atmosphere.

Direct exposure of the chromatograms to iodine vapour was found useful for the detection of certain unsaturated compounds, such as alcohols, esters, acids and some glycerides, which give yellow or brown spots on a white background. However, such compounds as symmetrical oleodipalmitin could not be located satisfactorily on chromatograms by this procedure. Lead tetra-acetate revealed monoglycerides as white spots on a black background and could be used to detect di- and triglycerides after they had been subjected to hydrolysis with the pancreatin spray.

PERILÄ, O. **Separation of saturated straight chain fatty acids. 3. Quantitative paper chromatography.** *Acta chem. scand.*, 1956, **10**, 143–144. [Finland Inst. Technol., Helsinki.]

For previous parts see Absts. 62, 1433, Vol. 26.

3. The acids are converted to their hydroxamic derivatives via their methyl esters and separated by circular paper chromatography. The spray reagent is ferric chloride. The spots are cut out and the ferric complexes of the hydroxamic acids are eluted with an acid ferric chloride solution and estimated photometrically at 520 mμ. For acids from formic to valeric the developing solvent is *n*-butanol : benzene : water (1 : 1 : 1) and for acids from caproic to pelargonic, benzene : formic acid : water (1 : 1 : 1). For acids from capric to cerotic, paper saturated with hydrocarbon is used, the developing solvent being acetic acid : water (9 : 1) saturated with hydrocarbon. After development

the dried paper is treated with 1·5 per cent. silver nitrate, washed and sprayed with 0·05 per cent. ethanolic *p*-diethylaminobenzylidenerhodanine, which gives silver spots visible in ultraviolet light. These are cut out and wet-ashed and Ag in the residue is estimated colorimetrically with dithizone.

H. G. Bray.

4071

BERGMANN, F. and SEGAL, R. **The separation and determination of microquantities of lower aliphatic acids, including fluoroacetic acid.** *Biochem. J.*, 1956, **62,** 542–546. [Dept. Pharmacol., Hebrew Univ.-Hadassah Med. Sch., Jerusalem.]

Fluoroacetate, formate, acetate and other fatty acids could be separated by 2-dimensional paper chromatography of the hydroxamates with, first, 95 per cent. ethanol containing 5 per cent. NH_3, pyridine and water (3 : 1 : 1), then 95 per cent. ethanol, dioxan, water and acetic acid (60 : 20 : 19 : 1) as solvent mixture. Mixtures of formate, acetate and fluoroacetate in water and in serum were quantitatively analysed by elution from the paper, oxidation with iodine to nitrite and colorimetric measurement of the azo dye produced on addition of naphthylamine.

A. Hepburn.

4072

JAMES, A. T. and MARTIN, A. J. P. **Gas-liquid chromatography: the separation and identification of the methyl esters of saturated and unsaturated acids from formic acid to *n*-octadecanoic acid.** *Biochem. J.*, 1956, **63,** 144–152. [Nat. Inst. Med. Res., Mill Hill, London, N.W.7.]

The previous method of the authors (Abst. 77, Vol. 22) for the separation of micro amounts of fatty acids has been extended to include acids up to C_{18} by using a gas density meter and the methyl esters of the acids. The methyl esters of the saturated acids C_1 to C_6 were separated at 78·7° C. with a stationary phase of liquid paraffin or dioctyl phthalate. Esters from C_5 to C_{18} were separated at 197° or 205° C. with a stationary phase of a vacuum stopcock grease or an extract of a heavy lubricating oil. A good separation of normal from *iso*- or *anteiso*-saturated acids and mono- from di-unsaturated acids was obtained, but saturated acids could be distinguished from unsaturated acids of the same chain length only by the chromatographic behaviour of the latter before and after chemical modification.—A. Hepburn.

4073

VANDENHEUVEL, F. A. and VATCHER, D. R. **Partition chromatography of aliphatic acids. Quantitative resolution of normal chain even acids from C_{12} to C_{24}.** *Anal. Chem.*, 1956, **28,** 838–845. [Fish. Res. Board Canada, Halifax, N.S.]

Use is made of reversed-phase chromatography on silicic acid columns treated with silane, with *iso*-octane as stationary phase and aqueous methanol as eluting solvent. The procedure is applicable to less than 50 mg. material and takes about 5 hr. An automatic device for changing the composition of the eluting solvent and a semi-automatic microburette driven by motor are described.

H. G. Bray.

4074

HASHMI, M. H. and CULLIS, C. F. **Paper chromatography of fatty acids and halogenated organic acids.** *Anal. chim. Acta*, 1956, **14,** 336–338. [Dept. Chem., Imp. Coll. Sci. Technol., London.] French and German summaries.

The developing solvent consists of propanol 70 and strong ammonia 30 per cent. All the acids can be detected by spraying with B.D.H. universal indicator, iodo acids by treating with chlorine to liberate iodine, which gives a dark colour with ammonia, and bromo acids by spraying with fluorescein and subsequent treatment with chlorine; this liberates bromine, which converts fluorescein to eosin. Fluorescein is also used to differentiate between bromo and iodo acids. R_F values are given for a number of simple fatty acids and their bromo and iodo derivatives.

H. G. Bray.

4075

MANUS, L. J. and BENDIXEN, H. A. **Effects of lipolytic activity and of mercuric chloride on the Babcock test for fat in composite milk samples.** *J. Dairy Sci.*, 1956, **39,** 508–513. [Dept. Dairy Sci., State Coll. Washington, Pullman.]

The decrease of fat and the increase of free fatty acids in composite milk samples after storage was apparently due to lipolytic hydrolysis. Tablets of $HgCl_2$ added to preserve the milk seemed to increase the hydrolysis, but this effect was slightly reduced by copper as $CuSO_4$. Hydrolysis of fat in milk preserved with $HgCl_2$ was effectively prevented by heating to 160° F. for 30 to 60 sec. to inactivate the lipase.—A. Hepburn.

4076

FREEMAN, T. R. and LEWALLEN, W. F. **Applying Hillig's rapid method for water-insoluble acids to fresh milk.** *J. Dairy Sci.*, 1956, **39,** 219–220. [Kentucky Agric. Exp. Stat., Lexington.]

Milk was separated within 15 min. after it was drawn from individual cows and water-insoluble fatty acids were estimated in the cream by Hillig's method (Abst. 2754, Vol. 24). Values were roughly inversely proportional to the fat content

of the cream and could be varied considerably by changing the setting on the skimmed milk screw. Dilution of the cream with skimmed milk produced a greater increase than dilution with water. The variations in values indicated lipolysis. Heating the freshly drawn milk at 160° F. for 30 min. to inactivate lipase was considered to give the best results.—A. Hepburn.

4077

CERUTTI, G. and TAMBORINI, A. Sulla determinazione del "numero di acido butirrico" nel burro. [**Estimation of the butyric acid number of butter.**] *Ann. Sper. agrar.*, 1956, **10,** 447–450. [Ist. Indust. Agrar., Univ. Milan.] English summary.

For the estimation 5 g. fat was melted, filtered and saponified with 2 ml. KOH solution and 10 g. glycerine, and was then treated while warm with 150 ml. saturated aqueous K_2SO_4 solution. After cooling to room temperature, 5 ml. H_2SO_4 solution, 1 part acid to 2 parts water, was added, then 10 ml. saponified coconut oil and some powdered SiO_2. After filtration, samples were titrated with 0·1 *N* NaOH. The difference between the value obtained and that from a blank was multiplied by 1·4 to give the butyric acid number.

Reichert Meissl Wollny number, Polenske number, Tortelli Jaffe reaction and butyric acid number are tabulated for Italian butters, ewe milk butter, margarine, whale oil, lard and adulterated butters. Adulterated butters tended to have lower butyric acid numbers than pure butter, for which the lowest value was 19·5.—D. Duncan.

4078

BARNETT, A. J. G. and TAWAB, G. A. **The estimation of the total volatile fatty acids in cheese.** *J. Dairy Res.*, 1956, **23,** 277–282. [Div. Agric. Biochem., Dept. Biol. Chem., Univ. Aberdeen.]

Total volatile fatty acids in different cheeses were estimated by extraction with ether in a Soxhlet apparatus for 8 hr. and micro-distillation from a Markham Kjeldahl apparatus. The results compared favourably with those obtained by the more complicated method of Smiley *et al.* (Abst. 2528, Vol. 16) and the method was more convenient for multiple analyses.—A. Hepburn.

4079

DOMART, C., MIYAUCHI, D. T. and SUMERWELL, W. N. **The fractionation of marine-oil fatty acids with urea.** *J. Amer. Oil Chem. Soc.*, 1955, **32,** 481–483. [Fish. Technol. Lab., Seattle, Wash.]

Menhaden oil fatty acids were fractionated at 1° C. by formation of urea complexes, with methanol as solvent; the molar ratio of urea to fatty acid was varied from 4·6 : 1 to 23·0 : 1. At molar ratios of 12 : 1 to 13 : 1 almost all the saturated and monoethenoid acids were removed as urea complexes. With higher proportions of urea to fatty acid, fractions with iodine values above 300 were obtained in the filtrates.

With a urea : fatty acid ratio of 9·2 : 1 the fatty acids of menhaden, herring, tuna and seal oils and oils from salmon eggs, viscera and heads were fractionated at different temperatures. At 25° and 1° C. the urea complexes included saturated and monoethenoid fatty acids; at − 30° an increased content of dienoic acids was found in the complexes.—G. A. Garton.

4080

COLLINS, F. I. and SEDGWICK, V. E. **A rapid spectrophotometric method for determining the linoleic and linolenic acid components of soybean oil.** *J. Amer. Oil Chem. Soc.*, 1956, **33,** 149–152. [U.S. Dept. Agric., Urbana, Ill.]

A procedure is described in which soya bean oil is subjected to alkali isomerisation using 11 per cent. KOH in glycerol at 180°C. in open bottles in a forced-draught air oven. Optical densities in methanol are then measured at 268 mμ. and 233 mμ. in special cells and the percentages of linoleic and linolenic acid are calculated from a nomogram.

G. A. Garton.

CORSINI, F. La determinazione degli acidi linoleico, linolenico e arachidonico nel latte e nel sangue. 3. La determinazione nel sangue. [**Estimation of linoleic, linolenic and arachidonic acids in milk and blood. 3. Estimation in blood.**] *Acta vitaminol.*, 1956, **10,** 64–69. [Ist. Clin. Pediat., Univ. Bologna.] French, English, German and Spanish summaries.

For previous parts see Absts. 4491, Vol. 21; 111, Vol. 25.

3. The fats are extracted from 2 ml. serum by boiling in Bloor's mixture (3 parts ethanol to 1 part ether) and saponified with KOH. The solvents are removed by evaporation and the fatty acids are then liberated with H_2SO_4 and extracted with ether. The ether extract is isomerised and examined in the Beckman spectrophotometer as described in Abst. 111, Vol. 25.

A negative value was commonly obtained for linolenic acid. The mean values for 5 estimations on the same sample were linoleic acid 55·6 ± 4·99, linolenic acid − 6·3 ± 2·48 and arachidonic acid 24·7 ± 3·06 mg. per cent.—D. Duncan.

HERMANOWICZ, W. and SIKOROWSKA, C. Badania nad oznaczaniem jodu w wodzie metodą chromatografii bibułowej. [**Estimation of iodine in water by paper chromatography.**] *Rocz. Państwowego Zakł. Hig.*, 1956, **7,** 177–184. Russian and English summaries.

Iodine is separated from other substances in water by paper chromatography and estimated by a modified catalytic cerium method in which ferric thiocyanate is used to measure the unreduced cerium ions. As little as 0·5 μg. I per litre could be estimated. (From English summary.)
A. Hepburn.

4105
ZIEVE, L., VOGEL, W. C. and SCHULTZ, A. L. **Determination of protein-bound radioiodine with an anion exchange resin.** *J. Lab. Clin. Med.*, 1956, **47,** 663–668. [Dept. Med., Veterans Admin. Hosp., Minneapolis, Minn.]
The standard procedure for estimation of protein-bound radio-active I in plasma in which the precipitate is washed 4 times with trichloroacetic acid was found to give a total loss of about 15 per cent. when the plasma contained an excess of inorganic ^{131}I. A column of Amberlite resin efficiently removed inorganic I from plasma in one passage and the loss of protein-bound I was about 4 per cent., but passage of plasma through a series of resin columns produced losses comparable with those of the standard method. Passage through a resin column gave results similar to those of the dialysis method.—A. Hepburn.

4106
TRINDER, P. **The improved determination of iron in serum.** *J. Clin. Pathol.*, 1956, **9,** 170–172. [Dept. Biochem., Central Lab., Royal Infirmary, Sunderland.]
Iron is extracted by trichloroacetic acid at 90° to 95° C. and the supernatant fluid obtained by centrifuging is treated with a 4 : 7-diphenyl-1 : 10-phenanthroline reagent in the presence of thioglycollic acid to give a red colour which is measured photoelectrically. In control experiments recoveries of ferric iron added to serum ranged from 99·5 to 102 per cent.—H. G. Bray.

4107
NEILL, D. W. and NEELY, R. A. **The estimation of magnesium in serum using titan yellow.** *J. Clin. Pathol.*, 1956, **9,** 162–163. [Dept. Biochem., Royal Victoria Hosp., Belfast.]
A modification of previous methods is described in which hydroxylamine is replaced as colour stabiliser by gum ghatti. The effect of Ca is eliminated by its addition to the Mg standards. The normal adult serum Mg level was found to be from 1·9 to 2·7 mg. per 100 ml.—H. G. Bray.

BRUEMMER, J. H. and O'DELL, B. L. **Inhibition of color development in the Lowry-Lopez phosphorus method by sulfhydryl compounds and its counteraction by copper.** *J. Biol. Chem.*, 1956, **219,** 283–286. [Dept. Agric. Chem., Univ. Missouri, Columbia.]

4112
KLEEMAN, C. R., TABORSKY, E. and EPSTEIN, F. H. **Improved method for determination of inorganic sulfate in biologic fluids.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 480–483. [Dept. Int. Med., Sch. Med., Yale Univ., New Haven, Conn.]

Protein is removed with trichloroacetic acid and the supernatant fluid is treated with a benzidine solution. The next day glass powder is added and the benzidine sulphate precipitated is separated by centrifuging and washed with a mixture of ethanol and ether. The precipitate is suspended in an alkaline sodium borate solution and the benzidine is estimated colorimetrically with sodium β - naphthoquinone - 4 - sulphonate, with which it gives a red colour in the presence of acetone.

4126

FEDER, E. and ANDREWS, F. C. **Measurement of butter quality by chemical and flavor tests.** *J. Farm Econ.*, 1956, **38**, 113–125. [Univ. Nebraska.]

Analyses of butter samples, primarily U.S. Grades B and C, showed that there was a small negative correlation between *p*H and water-insoluble acids (WIA) and a general tendency for fat acidity to increase as WIA increased, but the correlation between the last two was not high enough for accurate prediction of WIA from fat acidity. The Federal grades of butter, evaluated organoleptically, were negatively correlated with fatty acid and with WIA. The variation in chemical values was very large and tended to increase as a grade declined. Chemical values used as a measure of age and decomposition did not, therefore, appear to be related to flavour.

4127

SCHIFFMANN, J. **A microscopic method for evaluating the nutritional quality of brans.** *Ktavim, Rec. Agric. Res. Stat., Rehovot*, 1955, **4**, No. 3, 49–56.

Since bran consists chiefly of grain coats and very little endosperm, and since the aleurone layer of

the grain coat contains most of the nutrients in it, this was used as the basis of the method, which consisted in separating the grain coat from the endosperm and then estimating the area of aleurone layer in the grain coat under the microscope. The repeatibility of the results was good. The results were treated statistically and it is shown how they can be used to compare the feeding values of different brans. It was also shown that there was a highly significant negative correlation, $r = -0{\cdot}98$, between the percentage of carbohydrate and of grain coat, and a highly significant positive correlation, $r = +0{\cdot}94$, between the area of aleurone surface and the percentage of protein estimated chemically.—T. D. Bell.

4128

SCHIFFMANN, J. **A method for classifying brans according to feeding quality as determined by microscopic analyses.** *Ktavim, Rec. Agric. Res. Stat., Rehovot*, 1955, **4,** No. 3, 57–62.

A wide variety of terms, with no universal standard, are applied to bran. A method was sought by which all milling by-products could be classified and compared for feeding value and storage capabilities. The method included examination for adulteration by weed seeds and unwanted plant material, signs of rodent and insect infestation, mineral impurities and deterioration, and for nutritional value estimated by the microscopic method described in the previous Abst. Account was taken in the classification of possible added germs of the cereals, which enhanced the feeding value but reduced the storage quality. The method showed that of 933 samples of wheat, rye and barley brans obtained commercially in Israel, 12, 21 and 28 per cent., respectively, were valueless or actually harmful, and only 63, 54 and 52 per cent. were fair or good. The method is presented as a suggested basis for general use, which would need modification for other places and conditions.—T. D. Bell.

4129

SANDERS, G. P., HUPFER, J. A. and WISEMAN, H. G. **A phosphatase test for determining heat treatment of alfalfa meal.** *J. Dairy Sci.*, 1956, **39,** 561–567. [E. Utilization Res. Branch, Agric. Res. Serv., Philadelphia, Pa.]

Alfalfa hay contains both acid and alkaline phosphatase ; the latter is completely inactivated by the temperatures used in drying by artificial heat. The estimation of alkaline phosphatase by a modification of the spectrophotometric method of Sanders and Sagers (*J. Dairy Sci.*, 1947, **30,** 909), in which phenol is liberated from phenyl phosphate and reacts with 2 : 6-dibromoquinonechloroimide to give a blue indophenol, is used to detect the adulteration of meal made from artificially dried alfalfa with ground alfalfa hay, which is much poorer in carotene and other nutrients. As little as 1 per cent. adulteration could be detected.

MICROBIOLOGICAL

4133

FERNELL, W. R. and ROSEN, G. D. **Microbiological evaluation of protein quality with *Tetrahymena pyriformis* W. 1. Characteristics of growth of the organism and determination of relative nutritive values of intact proteins.**

ROSEN, G. D. and FERNELL, W. R. **2. Relative nutritive values of proteins in foodstuffs.** *Brit. J. Nutrition*, 1956, **10**, 143–156; 156–169. [Res. Dept., J. Bibby and Sons, Ltd., Liverpool.]

1. Studies were made on the effects of time, oxygen limitation and glucose concentration on the growth and metabolism of *Tetrahymena pyriformis*, W. The organism required a plentiful supply of oxygen. Production of ammonia was much less when the concentration of glucose in the culture medium was high, which was considered to be due to sparing of amino acids as a primary source of energy. With graded levels of protein growth of *T. pyriformis* did not necessarily accord with the values expected from accepted ratings.

Growth of *T. pyriformis* in relation to production of ammonia N was taken as an index of protein utilisation and used to calculate the relative nutritive values of the proteins of partly-purified meatmeal, fishmeal, herring meal, whalemeat meal, egg albumin, wheat germ, vitamin-free casein, which was used as the standard, soya bean meal, cottonseed meal, sunflower meal, linseed cake, overheated soya bean meal, sesame meal, groundnut meal, overheated groundnut meal, gelatine, gelatine plus 2 per cent. tryptophan, raw egg white and autoclaved egg white. The results were in general agreement with chemical data and with biological assays on growing rats. In general, the vegetable proteins were inferior to those of animal origin. Overheated groundnut and soya bean proteins had reduced nutritive values. The beneficial effect of supplementing gelatine with tryptophan was demonstrated. With fresh egg white, sterilised by filtration, *T. pyriformis* did not grow, but with autoclaved egg white a relative nutritive value of 115 was obtained.

2. Protein quality was estimated microbiologically with *T. pyriformis* in 20 different fat-extracted animal and vegetable foodstuffs without previous separation of the protein. These foodstuffs were vitamin-free casein, which was used as the standard, beanmeal, cottonseed meal, groundnut meal, sesame meal, soya bean meal, dried whole egg, herring muscle, herring meal, pilchard meal, whale meal, fin-whale meal, condensed whale solubles, spray-dried whale solubles, cod muscle, white-fish meal, Scottish fishmeal, bloodmeal, grassmeal and grass protein concentrate; of these, only the last 3 gave little or no growth. For satisfactory estimation a constant ratio of foodstuff N : glucose in the medium had to be maintained. The results compared favourably with the relative nutritive values for growing rats obtained by other workers.

These studies indicate that microbiological estimation of intact proteins may be a valuable preliminary to feeding trials on monogastric animals.—G. F. Garton.

[**The difference between " true " and " apparent " N retention, found by different types of method for evaluating the nitrogen of the feed.**] *Naturwissenschaften*, 1956, **43,** 203. [Inst. Physiol. Ernährung Tiere, Univ. Munich.]

Bender and Miller (Title 2726, Vol. 23) gave simplified methods for finding the net protein value of a food for rats either by ascertaining the N retained by estimation of N in their bodies or by calculating it from the water content of their bodies. The present work confirmed that, for whole egg and a complete rat diet, both methods gave results in good agreement with those obtained by multiplying Mitchell's biological value by the true digestibility, and the same was found by Wilmer (Fishing Indust. Res. Inst., Cape Town, *Annu. Rep.* **8,** 1955, p. 34) for fishmeal. But the mean N retention found by estimating body N by the Kjeldahl method in groups of rats of equal age and bodyweight of which some had and some had not the food in question was about 40 per cent. less than that found in the usual way, as difference between N consumed and N excreted. The former is taken to be the " true " N retention. On investigation, losses during analysis were found to account for 12 per cent. at most. It is thought probable that some of the N of the food is excreted in a combined form that escapes analysis, or in gaseous form. Further investigations are going on.—W. M. Deans.

ERWIN, E. S., DYER, I. A., ENSMINGER, M. E. and MOORE, W. **A portable metabolism stall for beef steers.** *J. Animal Sci.*, 1956, **15**, 435–439. [Dept. Animal Husb., State Coll. Washington, Pullman.]

A modification of a metabolism stall first proposed by Nelson *et al.* (Abst. 4188, Vol. 24) is described. The stall has wheels and a hand jack and tractor hitch to facilitate the exchange and loading of animals, easily removable water cups, a detachable rear door for use when transporting a steer, and rubber lining on the floor to make the animal more comfortable and to prevent it slipping or falling.—T. R. Preston.

4159

STRITE, G. H. and YACOWITZ, H. **A simplified method for estimating the rate of oxygen consumption of young chicks.** *Poultry Sci.*, 1956, **35**, 142–144. [Ohio Agric. Exp. Stat., Wooster.]

The respiration chamber consisted of an inverted 2000-ml. beaker painted black, in which the chicken stood on a wire mesh over a petri dish of 20 per cent. KOH solution ; the whole was sealed by standing in a glass dish of water through which the oxygen tube entered. The oxygen passed through a gas burette. Production of CO_2 could be estimated from the KOH solution.

In 10 chickens 2 weeks old fasted for 18 hr., 2 consecutive measurements of oxygen consumption gave mean values of 27·4 and 26·6 c.c. per kg. per min. Thyroprotein at 150 mg. per lb. feed produced a highly significant increase in oxygen consumption.—D. Duncan.

4160

HEUSNER, A. Technique de mesure de courte durée de la consommation d'oxygène et de l'activité du rat. Étude critique du circuit de Benedict. [**Technique for short-term measurements of oxygen consumption and activity in the rat. Critical study of the Benedict circuit.**] *C.R. Soc. Biol.*, 1956, **149**, 2254–2257. [Inst. Physiol., Fac. Méd., Strasbourg.]

The Benedict apparatus can be improved by keeping not only the metabolism cage but also the absorbers and the spirometer at constant temperature, by keeping both cage and circuit to the minimum volume, by increasing the rate of flow of air and by preventing the evaporation of urine. In such conditions the errors in estimation of oxygen consumption are only 2 to 3 c.c., or about 5 per cent. in 15-min. experiments with rats. The adaptations are described.—D. Duncan.

Simple methods are given for obtaining an estimate of the safe dose when the relation between log dose and effect is linear, with 3 examples from rat feeding tests, one with antimalarial drugs and the others with insecticides which might leave residues in foods.—W. M. Deans.

4167

HARPER, R. **Factor analysis as a technique for examining complex data on foodstuffs.** *Appl. Statistics*, 1956, **5,** 32–48. [Dept. Psychol., Univ. Leeds.]

A description of a sample of a given foodstuff may become very long, including the results of tests of a number of physical and chemical characteristics, which may involve both objective measurements and skilled judgements. Hence the comparison of different samples may become unmanageable, and factor analysis may serve to provide a simplified statement of the main features of the results. The assumption is made that there are only a small number of underlying variables, and that the result of each different test is influenced in a slightly different way by them. From a study of the interrelations of the test results from a large number of samples, estimates can be made of the number of factors required and of the factor levels in terms of linear combinations of test results. Even if the objective reality of the factors may be a matter of doubt, a useful simplification of the data is achieved, and at least some light is shed on the interrelations of the attributes under test.

The ideas of factor analysis are illustrated in this paper by reference to a study of Cheshire cheeses. A geometrical model is used to show how the measurements on the cheeses would be interpreted in terms of three independent underlying factors, and tentative suggestions are made as to how these factors could be identified objectively.

Unfortunately computational processes are laborious, but this drawback would be overcome if electronic computers were more numerous. There remains the question whether factor analysis is theoretically applicable to any given problem of this type, or whether special statistical techniques should be devised to fit the idiosyncrasies of each particular set of measurements.—I. McDonald.

4168

CHURCH, B. M. and LIPTON, S. **The use of an electronic computer in the estimation of sampling errors in a nutritional survey.** *Brit. J. Nutrition*, 1956, **10,** 27–32. [Rothamsted Exp. Stat., Harpenden, Herts.]

A valuable by-product of any exhaustive set of data consists of the information it contains on the accuracy which would have been obtained from only a sample of the data. In principle this information is quite easy to extract, but in practice little has been done on these lines because of the large amount of arithmetical drudgery involved. Now that electronic computers are coming into use, all that is necessary is to lay out appropriate routines of calculation, or "programmes", and the machine can work through the data and produce the results demanded. A description is given in this paper of a programme suitable for dealing with numerical sequences. This was applied to data from a diet survey consisting of 61 observations on weekly intakes of each of 13 dietary constituents relating to a total period of 63 weeks, the records for 2 of the weeks being missing. The programme takes account of missing observations and could easily be applied to any other numerical sequence.—I. McDonald.

4169

BOYNE, A. W. and GREIG, W. A. **The value of repeated observations in biological sampling.** *J. Agric. Sci.*, 1956, **47**, 145–149. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Increases in precision will often be obtained more economically by repeating observations on individual animals than by increasing the number of animals under study. A method is outlined whereby the advantage to be gained by such repetition may be predicted, for any measurement for which repeat readings are available on a number of animals. The method is applied to a number of haematological observations made on 8 pairs of monozygous twin calves on each of 3 successive days. Since the differences between the members of each pair are comparatively small, it is found that great improvements in accuracy can be achieved by making a number of observations on each animal. In making comparisons between unrelated animals, on the other hand, little additional accuracy can be obtained by making more than about 3 observations on each, since these repeats do not cut down the large between-animal variability. It follows that in these haematological measurements, at least, the full advantage of using identical twins is not achieved unless at least 10 readings are made on each.—I. McDonald.

4170

LUCAS, H. L. **Switchback trials for more than two treatments.** *J. Dairy Sci.*, 1956, **39**, 146–154. [Dept. Exp. Statistics, N. Carolina State Coll., Raleigh.]

A switch-back or double-reversal trial is one in which observations are made in 3 consecutive periods. One treatment is applied in the first and third of these, and a second treatment in the middle period. The comparison of the effects of the treatments on the same animal is very much more accurate than a comparison between animals, at least in experiments on the performance of dairy cattle. Period effects must be eliminated by using pairs of cows and applying the treatments in reverse order to the second cow.

Switch-back designs can be extended to compare more than 2 treatments by taking each possible pair of treatments and applying these as described above. A comparison of p treatments would thus require the use of $p\ (p-1)$ cows. The method of analysis for such an experiment is described in great detail, as are also reduced designs with half the number of cows, which are permissible when the number of treatments is odd and not less than 5.

It may not always be convenient to put all the cattle on experiment at the same time, but a valid analysis is still possible provided that they are divided into blocks in a suitable way and the animals in one block are put on experiment at one time. A description is given of the consequent modifications of the analysis, and also of the treatment of any missing values.

The method of analysis is illustrated numerically from uniformity data.—I. McDonald.

4171

GESELLSCHAFT FÜR ERNÄHRUNGSPHYSIOLOGIE DER HAUSTIERE. Richtlinien zur Durchführung und Auswertung von praktischen Fütterungsversuchen an Haustieren. [**Guide to the performance and interpretation of practical feeding experiments on domestic animals.**] *Ztschr. Tierernährung Futtermittelk.*, 1956, **11**, 126–130.

Standard procedures for evaluation of feeds are suggested. Proper training and supervision of technical assistants is essential. Feeds should be analysed chemically or when necessary biologically for crude protein, crude fat, crude fibre and ash, and for other components as necessary; for chemical analyses the methods in "Handbuch der Landw. Versuchs- u. Untersuchungsmethodik", Bd. 3, Neumann-Verlag, Radebeul and Berlin, 1951, are suggested.

Animals of the same strain, age and sex and similar in bodyweight should be used, and preferably those similar in conformation and state of nutrition, and they must pass a veterinary inspection. Young animals should when possible be littermates and the feeding of the mother in pregnancy should be known, as well as that of the young from birth. In arranging groups the arithmetic mean of the initial weights should be similar and also the distribution of individual weights. For dairy and beef cattle and sheep the smallest group should be 8, young calves and pigs 6, chickens 30 and laying hens 60.

A "normal" group should always be included. For vitamin assays one group should always receive the carrier without the active substance. Digestibility trials are sometimes useful. The duration of experiments with dairy cows should be at least 2 months, with a fore-period of 1 to 2 months, but for mineral preparations a year is needed; with fattening cattle, calves, sheep and pigs the whole fattening period; with chickens at least 8 weeks, young birds 12 weeks, and laying hens at least 9 months beginning in October.

It is advantageous to use 3-day mean weights. Fattening animals should be weighed weekly. Yield of fattening animals is based on weight increase and carcase studies. Milk yield and fat content must be known and analyses of dry matter and protein may be necessary. For laying trials trap-nests must be used.

The evaluation and presentation of results is discussed briefly. Comparison of results with

those of others is possible only when all the conditions of environment, number of feedings and nutritional state of the animals are comparable.

D. Duncan.

4172

HOMB, T. Bestemmelse av biologisk verdi av proteinet i fôrmidler. [**Estimation of the biological value of protein in fodders.**] *Nord. Jordbrugsforsk.*, 1955, **37**, 106–124.

This survey deals with estimation of biological value by N balance experiments and the importance of the N content of the ration, the estimation of metabolic N in faeces, the negligible effect of fat, the consistency of the faeces, true and apparent digestion, endogenous N in urine and the reliability of the balance method. Six older methods are rejected for obvious sources of error. It is not, at present, possible to assess biological value from a complete analysis of amino acids and knowledge of the requirement of each one, but Mitchell and Block's method of comparison with egg protein gives results in good agreement with balance tests. It is impossible to say whether, or to what extent, such a chemical method may be developed to replace animal experiments.—I. Leitch.

4173

ANDERSON, R., CHENG, E. and BURROUGHS, W. **A laboratory technique for measuring phosphorus availability of feed supplements fed to ruminants.** *J. Animal Sci.*, 1956, **15**, 489–495.

The technique described made use of fermentation tubes as artificial rumens.

Cellulose digestion during a 24-hr. fermentation period by washed suspensions of rumen inocula to which were added the sources of phosphorus under investigation was estimated. As a preliminary a P-deficient medium was used, and then a standard phosphate source, 2 parts dibasic Na phosphate and 1 part monobasic K phosphate, was tested. The amount of phosphate was expressed in μg. per ml. medium. Maximum response to P was facilitated by the addition of specially hydrolysed casein or feather meal. The rumen inocula were obtained from cows with a fistula, and results from different cows or on different days agreed well. When the method was used to compare P sources commonly in use for cattle, composite dicalcium phosphate was almost as good as the standard phosphate when added in amounts supplying 10, 20 or 40 μg. P per ml. medium. An acidulated phosphate product at the same levels was only 60 to 70 per cent., steamed bonemeal 30 per cent., and Curação rock phosphate 10 per cent. as effective. Soft phosphate with colloidal clay was ineffective at 10 μg. and only 2 per cent. effective at higher levels. The technique is not yet perfected, and further work is necessary to establish its value in relation to actual conditions.—T. D. Bell.

4174

MEYER, J. H. and LOFGREEN, G. P. **The estimation of the total digestible nutrients in alfalfa from its lignin and crude fiber content.** *J. Animal Sci.*, 1956, **15**, 543–549. [Dept. Animal Husb., Univ. California, Davis.]

Lignin, crude fibre and N were estimated in 31 widely different samples of alfalfa hay, which were also used in 152 digestibility trials with wethers. Calculated total digestible nutrients (TDN) of the hays ranged from 36·2 to 63·4 per cent. The regression of lignin content of dry matter on TDN was $y = 84{\cdot}57 - 3{\cdot}21\,x$, with correlation $r = -0{\cdot}88$. For crude fibre the equation was $y = 79{\cdot}7 - 0{\cdot}84\,x$, with $r = -0{\cdot}86$. The correlation with percentage N was not quite so close, $r = +0{\cdot}77$, with the equation $y = 9{\cdot}25\,x + 27{\cdot}8$. TDN could be satisfactorily predicted from either lignin or crude fibre content, but this applies to alfalfa hay, and not to other forages.—T. D. Bell.

4175

VAN DER KLEY, F. K. **A simple method for the accurate estimation of daily variations in the quality and quantity of herbage consumed by rotationally grazed cattle and sheep.** *Netherlands J. Agric. Sci.*, 1956, **4**, 197–204. [Div. Grassland Husb., Agric. Univ., Wageningen.]

The method requires careful cutting of as many sample areas of the pasture as possible. The herbage must be cut to a constant level, below the level grazed by the animal, and hand clipping is recommended. It is shown how the daily quantity of herbage available to the grazing animal, and the quality of that day's herbage, can be estimated from the clippings. With careful clipping and analysis, the accuracy is high. Quality and intake of dry matter were found to decline on consecutive days on the same pasture, but on the first day excess might be taken.—T. D. Bell.

4176

VAN DER KLEY, F. K. Is radioactief bariumsulfaat bruikbaar om de hoeveelheid mest van weidend vee te schatten? [**Can radio-active barium sulphate be used to measure the quantity of faeces produced by grazing cattle?**] *Landbouwk. Tijdschr.*, 1956, **68**, 665–671. [Afd. Graslandcultuur, Landbouwhogesch.] English summary.

The characteristics of a suitable inert marker for measurements of fodder eaten and residues excreted by grazing cattle are that it should be well tolerated, not retained, uniformly distributed in faeces and excreted at a uniform rate. In tests with 4 bullocks, of about 450 kg. weight, fed indoors on cut grass, and given, in the main part of the experiment, for 16 days 2 capsules daily, to provide 2, 4, 6 or 8 g. barium sulphate with 0·1

mC. ^{35}S per g., there was no sign of intolerance, but $BaSO_4$ tended to be retained, was not uniformly distributed in faeces and was irregularly excreted. Such a heavy substance is therefore considered unsuitable as a marker.—I. Leitch.

4177

DEIJS, W. B. and BOSMAN, M. S. M. De bepaling van de verteerbaarheid van voedingsstoffen met behulp van plantaardige gekleurde verbindingen, die in het voer voorkomen. [**Estimation of the digestibility of feedingstuffs with the help of plant pigments that are present in the feed.**] 1. Algemene beschouwingen en colorimetrie. [**1. General considerations and colorimetry.**] 2. Toepassingen. [**2. Applications.**] 3. Plantaardige gekleurde verbindingen in gras en in mest van runderen. [**3. Plant pigments in grass and in faeces of cattle.**] 4. Toepassing bij grazende runderen. [**4. Application to grazing cattle.**] *Centraal Inst. Landbouwk. Onderzoek, Overdruk* No. 213–214, 1953 (1954), 155–160, 160–166 ; *Overdruk* No. 275–276, 1954 (1955), 219–223, 224–228. English summary.

1. An extract of grass made with 85 per cent. acetone has 2 maxima in the absorption spectrum, at 433 and 665 mμ. When oxalic acid, 0·03 *M*, is added to the acetone, the extract is green and the absorption maxima are at 412 and 666 mμ., which correspond to phaeophytin. Similar extracts of faeces showed maxima at 414 and 665 mμ. with acetone alone, and oxalic acid increased the optical density at 414 mμ. Extracts of silage with acetone alone gave maxima at 412 mμ. and oxalic acid had little effect. Acetone extracts of hay had little colour and no clear maximum ; oxalic acid increased density and gave a maximum at 414 mμ. When, therefore, plant chromogens are to be used in the estimation of digestibility, to get comparable results with feed and faeces acetone, 85 per cent. with 0·03 *M* oxalic acid, should be the solvent and absorption should be measured at wavelengths between 415 and 420 mμ.

2. Tests were made with cows stall-fed on hay, silage and dried grass, the silages made with molasses and with A.I.V. fluid, or stall-fed on fresh cut grass, or grazing, the pasture being sampled at the same time. In all the feedingstuffs and in faeces, dry matter (soil-free), crude protein, pigments and Cu were estimated. Digestibilities of crude protein by the chromogen method and calculated by the method of Dijkstra (*Landbouw*, 1951, **13,** 23) agreed well. Cu was absorbed in each of the tests in which the cows were stall-fed, most from molassed silage, and the Cu content of blood rose correspondingly. In 7 grazing tests with 52 cows in all, mean balance of Cu was positive only once.

3. Chromatography on aluminium hydroxide separated 4 pigment fractions from extracts of fresh grass and of faeces of grazing and stall-fed cows made with acetone, 85 per cent., containing 0·03 *M* oxalic acid. These were : carotene, phaeophytin, xanthophyll and a residual mixture of porphyrins of which one was phylloerythrin.

4. Another experiment with grazing cattle is described in which pigments were extracted from grass and faeces with acetone and oxalic acid, but as reference chromogen the residue after removal of the carotene and xanthophyll fractions was used. Again digestibility of crude protein so measured agreed well with that calculated by Dijkstra's method. Cu and Mn were estimated also. Per kg. dry matter grass contained 9·3 mg. Cu and 55·0 mg. Mn, and of these amounts 1·8 and 4·2 mg. were absorbed. When grass was cut into top, middle and base portions chlorophyll, crude protein and Cu in terms of dry matter all decreased from top to bottom ; the ratio of crude protein to Cu remained almost the same. The correlation between pigment and protein reduces the error when the cut sample of grass does not exactly correspond to the grass eaten.

Since the absorption spectra of extracts of grass in acetone, with and without oxalic acid, have maximum densities at 412 mμ. and 430 mμ., and the graphs of density cross at 422·5 mμ., it is suggested that an extract of grass without oxalic acid may be comparable, in terms of phaeophytin, with an extract of faeces when examined at that wavelength, and the possibility will be tested.

CARENA, A. L'influenza della penicillina, della streptomicina e della cloromicetina sulla flora microbica e sulle qualita casearie del latte. [**The influence of penicillin, streptomycin and chloromycetin on the microbial flora and suitability of milk for cheesemaking.**] *Ann. Sper. agrar.*, 1956, **10**, 865–897. [Ist. Zootec. Piemonte, Turin.] English summary.

The milk samples were obtained from healthy cows and to them were added, per ml., 0·1, 0·5, 1 or 5 units penicillin, or 0·1, 0·5 or 2·5 μg. streptomycin, or 0·1, 0·5 or 2·5 μg. chloromycetin. Larger amounts of antibiotics prevented fermentation. The results of 1890 tests were analysed statistically.

Penicillin was most effective in slowing down the production of lactic acid in the milk, which was reduced by 35 per cent. after 4 hr. even with the smallest amounts of penicillin. After 12 hr. the acidity was almost normal when only 0·1 unit penicillin per ml. was added, but the larger doses still retarded acid formation to from 40 to 25 per cent. of the normal. The largest amounts of streptomycin and chloromycetin reduced acid formation in 12 hr. to 50 and 13 per cent. of normal. Reduction of methylene blue was affected in the same way as acidity.

The rate of coagulation was appreciably slower with 0·5 unit or more of penicillin or 2·5 μg. chloromycetin per ml., but the effect of streptomycin was slight. The maturation of curd was much delayed by chloromycetin, least by streptomycin. There was no interaction between the antibiotics. All the effects were highly significant.

TOEPFER, E. W., PRITCHETT, C. S. and HEWSTON, E. M. **Boneless beef: raw, cooked, and served. Results of analyses for moisture, protein, fat and ash.** *U.S. Dept. Agric. Tech. Bull.* No. 1137, December 1955, pp. 33. [Human Nutrit. Res. Branch, Agric. Res. Serv.]

This report is in 3 parts.

Beef as cut for the United States army is known as 4-way boneless beef: 7 cuts for oven roasts or broiled steaks, 5 for pot roasts or Swiss steaks,

diced beef for stews, and ground beef for meat loaves, hamburgers and the like. Army and civilian retail cuts are shown in a diagram.

In 1951 preliminary studies were made of yield and composition of the different cuts and forms, raw frozen or after cooking by army methods, from 8 carcases of Army grade B (= U.S. Choice). The detailed results are given in tables. Boneless beef formed 66 per cent. of carcase weight. Thaw juices ranged from 3·8 to 5·0, mean 4·2 per cent. of raw frozen weight of cuts. Yields of drained cooked beef ranged from 64 per cent. of raw frozen beef for oven roasts (drippings 3·6 per cent.) to 77 per cent. for Swiss steaks. Energy, moisture, protein (N × 6·25), fat, ash, and, in some, total carbohydrate by difference are tabulated per 100 g. of the different cuts and forms, raw and cooked, and of the drippings. The factors for calculating energy value of different products are stated. Losses of protein and fat in thaw juices were small, as were losses of protein in drippings, except for Swiss steaks and pot roasts. On a carcase basis, the cooked beef contained 85 per cent. of the energy in the raw, 94 per cent. of the protein and 82 per cent. of the fat. From data on separable lean and separable fat, it was deduced that on the average, the separable fat contributed about half the energy of the cooked beef though it formed only about 20 per cent. by weight of the raw beef.

In the second part a large-scale study of plate waste from oven roasts, with fat trimmed to 3/4 in. or to 1/4 in., is reported (23 meals, 4854 men, at one army location). Trimming reduced percentages of beef not served from 7·2 to 4·3 and of plate waste from 6·0 to 4·4, but not drippings or scrapings. Of protein in raw beef issued, about 80 per cent. was in beef presumed eaten, and trimming made little difference. On the assumption that the fat dripping from trimmed cuts would be used and consumed as gravy, and no more than this, it was concluded that further trimming of surface fat at meat-packing plants would save weight to be handled and freezing space without impairing nutritive value.

Finally, in 1952–53, a study of composition of boneless beef as cooked and served on a still larger scale (542 meals, nearly 110,000 men, at 5 army locations in different states) is reported. Weight of beef issued varied considerably from the standard issue ; the amount, but not the percentage, of plate waste was a linear function of weight issued. Plate waste per standard issue for 100 men (42 lb. for most forms) ranged from 1·132 ± 1·08 lb. for hamburgers to 4·417 ± 2·33 for broiled steaks. Percentage of fat in plate waste was significantly correlated with that in beef served.

For protein and fat content of raw beef, the values for 8 carcases (part 1) were found to be representative of those in the largest field study, except for ground meat, which had significantly more fat in the field study. The beef presumed eaten was calculated to contain 67 per cent. of the energy, 84 per cent. of the protein and 51 per cent. of the fat of the beef issued. The plate waste contained 10, 6 and 11 per cent. and the unserved edible beef 7, 9 and 6 per cent.—W. M. Deans.

4188

FENTON, F., FLIGHT, I. T., ROBSON, D. S., BEAMER, K. C. and HOW, J. S. **Study of three cuts of lower and higher grade beef, unfrozen and frozen, using two methods of thawing and two methods of braising.** *Cornell Univ. Agric. Exp. Stat. Memoir* No. 341, March 1956, pp. 68. [New York State Coll. Home Econ.]

One-third of the beef produced in the United States in 1953 is said to have been from dairy animals, and in New York State about 300,000 cows and 700,000 calves are annually slaughtered off dairy farms. Only certain parts are sold as beef ; the rest goes for sausages or processing.

To get information about cow beef, a statistically planned experiment was made with 4-lb. boned and rolled joints from top and bottom round and chuck from 6 cow carcases, U.S. Utility grade, and 6 bullock carcases, U.S. Good or Choice grade. After storage in cellophane wrappings for a few days in a household refrigerator or for 6 months at — 18° C. the meat was braised in an oven at 149° C. (300·2° F.), or in a pressure cooker at 116° C. (240·8° F.) and 10 lb. pressure with intermittent escape of steam. Some of the deep-frozen meat was thawed to 1·1° C. (34° F.) before cooking. There were 144 joints in all. In raw and cooked meat moisture, fat, N, vitamin B_1 and riboflavin were estimated. The results are tabulated and analysed statistically.

For all the joints mean loss of weight was 39 per cent., fat loss in drip 4, mean evaporation loss 20 and cooking drip 14 per cent. Among significant differences were the following. Weight loss was greater for cow beef and with pressure-braising. Fat loss was greatest from chuck. Evaporation loss was greater with pressure-braising but cooking drip was less. Cooking drip was greater for cow beef. Differences in shrinkage were probably not of practical importance.

Moisture content, fat content after trimming and N content (mean 15 per cent.) of lean on a dry fat-free basis did not differ between grades. When cooked, chuck had least N.

Mean vitamin B_1 content of lean on a dry fat-free basis was 0·273 g. per 100 g. raw and 0·104 cooked (drip not analysed). Chuck had less than round. For cow beef only, thawing before cooking and oven-braising were advantageous.

Mean riboflavin content was 1·34 mg. per 100 g. raw and 0·795 cooked. Chuck had more than

round. Pressure-braising was at least as good as oven-braising. Freezing, and thawing before cooking, did not affect riboflavin content.

MIYADA, D. S. and TAPPEL, A. L. **The hydrolysis of beef proteins by various proteolytic enzymes.** *Food Res.*, 1956, **21,** 217–225. [Dept. Food Technol., Univ. California, Davis.]

For the extraction of meat proteins 0·1 *N* NaOH was superior to 0·5 per cent. KCl or 20 per cent. urea, and when collagen and elastin were estimated in the residue the values agreed well with those deduced from the amount of hydroxyproline present (for method of estimating hydroxyproline see Abst. 4061, Vol. 26).

Soluble beef proteins were well hydrolysed by papain, bromelin, ficin, trypsin and Rhozyme P-11, a fungal enzyme. Collagen was hydrolysed by all 5 and elastin by papain and ficin. All were powerful proteolytic enzymes and might be useful for making meat tender.—A. Hepburn.

HENRICKSON, R. L., BRADY, D. E., GEHRKE, C. W. and BROOKS, R. F. **Dehydrated pork studies. Removal of glucose by yeast fermentation.** *Missouri Agric. Exp. Stat. Res. Bull.* No. 586, June 1955, pp. 12.

To prevent the "browning reaction" in dried pork, which was thought to be due to the reaction between amino groups and free aldehyde groups of glucose, an attempt was made to remove the glucose by fermentation with yeast.

Washed cells of *Saccharomyces cerevisiae* were used in concentrations of 1·7 to 20 per cent. with pork ground to 1/2 or 1/8 in. or blended in a Waring blendor. Pork was used cooked or uncooked. The 1/2-in. and blended products had an unsatisfactory texture. During 2 months' storage the 1/8-in. particles treated with yeast were more stable than those not treated. The best product was obtained with 5 per cent. yeast and fermentation for 4 hr. When 10 or 20 per cent. yeast was used, yeast flavour was detected in the finished product. Fermenting for more than 4 hr. did not improve the process. When the pork was cooked the glucose was more readily fermented and the product was better.—T. D. Bell.

4193

DESKINS, B. and WINTER, A. R. **Cooked, edible meat in parts of poultry. 2. Geese.** *J. Amer. Dietetic Assoc.*, 1956, **32,** 211–213. [Sch. Home Econ., Ohio State Univ., Columbus.]

Studies similar to those on chickens (broilers) (Abst. 4677, Vol. 25) were made on young geese aged from 8 to 24 weeks. For 55 geese, liveweight from 7 to 13 lb., dressing loss was between 13 and 14 per cent. and average evisceration loss was 28·5 per cent. of liveweight. More detailed study of 19 geese showed that the average cooking loss of the carcase, excluding giblets and neck, was 38 per cent. at 24 weeks (7 birds) and 33 per cent. for the younger birds; loss of fat accounted for from 2·8 to 9·4 per cent. of this, increasing with age. Legs and breast formed a smaller percentage of the carcase than in chickens of the same age. In cooking, breast lost 39·3, back 38·3, legs 34·0 and wings 26·0 per cent. Edible meat formed 39 per cent. of eviscerated weight in the younger birds and 42 per cent. in the older, compared with 51·4 per cent. in chickens. In the cooked carcases, edible meat amounted to 64 per cent., compared with 69 per cent. in chickens.—W. M. Deans.

FEKETE, L. A vágóhídi vér tartósítása nyáron. [**Conservation of slaughterhouse blood in summer.**] *Rep. Fac. Animal Husb., Hung. Univ. Agric. Sci.*, 1955, **1,** No. 8, 13–21. [Inst. Animal Breeding, Univ. Agric. Sci., Budapest.] Russian, German and English summaries.

Blood from the slaughterhouse was mixed within 6 hr. of collection with an equal weight of barley grits and the mixture was dried in the open in layers not more than 2½ to 3 cm. deep, stirred every half hour. Drying took about 4 to 6 hr. in the open, longer in a closed air space. As no heat was needed, the process was very cheap. The product was free from disagreeable odour and could be stored. One man without mechanical aids could preserve about 250 kg. blood in 8 hr. The product was readily accepted by pigs and poultry and also by breeding bulls. If pig blood is used it is advisable to boil the feed for 10 min. before giving it to pigs, but the risk of spreading infections could be reduced by giving pig blood to poultry and blood of other species to pigs. (From English summary.)—D. Duncan.

the distribution and migration of contaminated fishes on the basis of the compiled data of radiological survey. 2. Actual state of radiological contamination in fishes and its possible routes on the basis of the findings of "Bikini Expedition". 3. Radio-chemical studies of contaminated fish. *Jap. J. Med. Sci. Biol.*, 1955, **8**, 337–346; 347–358; 359–372. [Dept. Food Control, Nat. Inst. Health, Tokyo.]

4196

RAMOS, V. P. Auto-oxidação e antioxigénios nas gorduras alimentares. [**Auto-oxidation and anti-oxidants in edible fats.**] *Agronom. lusitana*, 1955, **17**, 17–53. [Estação Agronom. Nac., Portugal.] English summary.

The material studied consisted of 12 samples of natural fats. Their stability to active oxidation at 100° C. ranged from 3 hr. for both liquid and solid phases of palm oil to from 9 to 17 hr. for different olive oils. In an incubator at 60° C. the stability of palm oil was 3 days, that of pure groundnut oil 9 days. In ordinary storage conditions the solid fraction of palm oil was stable for 8 months, the liquid fraction for over 12.

The stability of whole palm oil and of both fractions was slightly improved by from 0·01 to 0·03 per cent. nordihydroguaiaretic acid, butylhydroxyanisole, ethyl gallate or hydroquinone. Beneficial effects of critic and phosphoric acids are ascribed to their forming inactive complexes with Fe or other metallic oxidants.—D. Duncan.

4197

BRIDGES, R. G. **The fate of labelled insecticide residues in food products. 5. The nature and significance of ethylene dibromide residues in fumigated wheat.** *J. Sci. Food Agric.*, 1956, **7**, 305–313. [Pest Infestation Lab., London Rd., Slough, Bucks.]

For previous parts see Abst. 3902, Vol. 20 (DDT); *J. Sci. Food Agric.*, 1955, **6**, 251; 261; 269 (methyl bromide).

5. Laboratory studies with ethylene dibromide labelled with ^{82}Br showed that thorough airing is needed to remove ethylene dibromide sorbed by wheat. There was evidence suggesting that ethylene dibromide reacted with some constituent of wheat protein, but only to a very small extent. On heating, some of the ethylene dibromide sorbed on wheat breaks down to HBr and ethylene glycol, which is less toxic than ethylene dibromide, but may react with the SCH_3 group of methionine; and the HBr causes some breakdown of starch granule sheaths. None of these changes is considered at all likely to endanger human beings or affect the nutritive value of wheat for them; there may be some risk to chickens given unheated wheat.—W. M. Deans.

4198

LE GROS CLARK, F. **A new assize of bread.** *Med. Officer*, 1956, **95**, 289–290.

The question of the extraction rate of flour is rediscussed, with criticisms of the opposing points of view. The suggestion is made that flour of 70 per cent. extraction should be enriched with riboflavin as well as with vitamin B_1, nicotinic acid and Fe, but to assume that such enrichment will restore the difference between flour milled to 70 per cent. and that milled to 80 to 85 per cent. extraction is not wise.—W. M. Deans.

4199

BECHTEL, W. G., HAMMER, G. E. and PONTE, J. G. (Jr.) **Effect of calcium stearyl-2 lactylate in bread made with nonfat milk solids of varying baking quality.** *Cereal Chem.*, 1956, **33**, 206–212.

Addition of 0·5 per cent. calcium stearyl-2 lactylate to the dough improved the quality, especially the texture, of bread baked from flour containing 3, 4, 6 or 8·5 per cent. roller- or spray-dried non-fat milk solids, irrespective of the baking quality of the latter. Experiments with wheat starch and gluten separately suggested that calcium stearyl-2 lactylate alters the structure of gluten and retards the swelling of starch during baking.—W. M. Deans.

[**Causes of discolouration of steamed potatoes. 3. Significance of time of steaming, temperature and possible enzyme residues.**] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1956, **103**, 285–290. [Deutsch. Forschungsanst. Lebensmittelchem., Munich.]

Previous papers dealt with chlorogenic acid (Abst. 188, Vol. 26) and bivalent iron (Abst. 1540, Vol. 26).

3. With or without added Fe, maximum blackening of potato meal or dough required 20 minutes' steaming. Discolouration by added Fe did not occur unless the potatoes reached at least 80° C. during steaming, and that was about the temperature at which chlorogenic acid was set free. All

these experiments were with a single variety (Ackersegen), but chlorogenic acid in varying amount was found in 5 other varieties liable to blacken on cooking. No evidence that blackening was caused by enzyme residues was found. It was concluded that blackening was due to the reaction between bivalent Fe, chlorogenic acid and some unknown substance in potatoes.

W. M. Deans.

LEE, F. A. **The effect of sunlight on crude lipids extracted from fresh and frozen vegetables.** *Food Res.*, 1956, **21**, 254–263. [Dept. Food Technol., New Jersey Agric. Exp. Stat., Rutgers Univ., New Brunswick.]

When crude lipids prepared as previously described (Abst. 1734, Vol. 25) from asparagus, sweet corn, Lima beans, peas, spinach and snap beans, blanched or unblanched and fresh or stored for a year or more at 0° F., were exposed for up to 120 min. to bright mid-day sunlight, peroxides developed more rapidly and to a greater extent in unblanched than in blanched samples, except in Lima beans. Frozen storage made little difference except to sweet corn (*cf.* Abst. 190, Vol. 26). Little peroxide was found after brief (5-min.) exposure. Lipids from stored blanched spinach developed little peroxide, which is attributed to their high carotene content. The absorption spectra of solutions of the crude lipids in ether are reproduced. There was evidence that visible light was the active agent, not ultraviolet; this is being investigated.—W. M. Deans.

4204

REITH, J. F. Over het gebruik van difenyl als schimmelwerend middel bij sinaasappelen en andere citrusvruchten. [**Use of diphenyl as protective against fungus for oranges and other citrus fruits.**] *Voeding*, 1956, **17**, 169–174. [Afd. Chem. Levensmiddelenleer, Rijksuniv. Utrecht.]

The amount of diphenyl to be found on treated fruit, the metabolism of diphenyl in experimental animals and its toxicity are briefly discussed on the basis of published reports. The Netherlands has, so far, made no regulation of its use; the United Kingdom prescribes an upper limit of 40 mg. per sq. in wrapping paper, the United States does not restrict its use.—I. Leitch.

4205

NIESAR, K. H. Lagerung und Qualität des Leinsamenmehles. [**Storage and quality of linseed meal.**] *Ztschr. Tierernährung Futtermittelk.*, 1956, **11**, 109–112. [Inst. Physiol. Tiere, Univ. Munich.] English summary.

A sample of linseed meal was found to contain crude fat 33, crude protein 20 and ash 4 per cent. and, in mg. per 100 g., Ca 266, P 630, vitamin E 20, vitamin B_1 1, riboflavin 0·6, nicotinic acid 3·9 and vitamin B_6 2.

The meal, stored in sacks at the temperature and humidity of a room or of a byre [not further specified], with or without dry ice to provide an atmosphere of CO_2, was examined after 2, 5 and 10 months; vitamin E was estimated and acid value, saponification value, iodine value and Lea (peroxide) value were ascertained. Although after 12 months there was no change in appearance, feel, smell or taste the chemical studies revealed moderate changes. After 5 months the vitamin E content had fallen by between 15 and 20 per cent., and then remained steady; the fall may have been due to the grinding. After 10 months the acid value had increased tenfold, the saponification value had decreased by about 20 per cent. and the peroxide value had doubled. Changes in iodine value were slight until 10 months had elapsed, and there was no fall then when dry ice was added; otherwise, dry ice made little difference. Feeding trials would be required to test whether these changes affect the feeding value.—W. M. Deans.

4206

DEIJS, W. B. and SPRENGER, J. J. I. De bereiding van eiwit uit groenvoedergewassen. [**The preparation of protein from green crops.**] *Centraal Inst. Landbouwk. Onderzoek, Overdruk* 166, 1952 (1953), 178–185. English summary.

Laboratory methods of isolating protein from green crops are briefly discussed. The Powling process (E. M. Bentall and Co., Maldon, Essex) is described in terms of composition of the product, a press cake, residue, loss of soluble components, and costs. The machinery is thought to be satisfactory, but not the details of processing. The main application, when these details have been improved, may be to the conversion of crop residues, such as beet leaves, to more valuable feeds.—I. Leitch.

DIJKSTRA, N. D. De verandering van het drogestofgehalte van het geënsileerde gras tijdens de bewaring. [**Changes in dry matter content of ensiled grass during conservation.**] *Landbouwk. Tijdschr.*, 1956, **68**, 724–726; *Landbouwvoorl.*, February 1956, 83–84. [Rijkslandbouwproefstat., Hoorn.] English summary.

Data for the dry matter (DM) of grass, fresh or wilted, and that of the corresponding silage, made with or without preservative, are shown in a graph and, from the equation of the fitted parabola, a table is derived giving the dry matter of silage from grass of 13 to 50 per cent. DM by unit steps. The point at which no change occurs is 22·8 per cent. DM; above that, moisture is lost, below it moisture is gained.—I. Leitch.

4209

MURDOCH, J. C., HOLDSWORTH, M. C. and WOOD, M. **The chemical composition and loss of nutrients in silage made with the addition of sodium metabisulphite and halogenated acetate of glycol.** *J. Brit. Grassland Soc.*, 1956, **11**, 16–22. [Nat. Inst. Res. Dairying, Univ. Reading.]

Metabisulphite was used at rates of from 4 to 16 lb. per ton of herbage. In 3 small-scale trials the silages produced were generally of better quality than the control silages made without additive. Nutrient losses were lower and volatile acid and base formation were reduced. There appeared to be little effect on lactic acid production. In one instance metabisulphite had little effect because, it is suggested, rain leached it out of the silage. Results from 2 trials on a larger scale were not clear-cut, and it is suggested that this was due partly to the difficulty of securing even distribution of the metabisulphite. The results of 2 preliminary trials with the glycol compound ("Sovilon") were inconclusive.—J. L. Corbett.

4210

KARPOV, M. C. Primenenie bakterial'nykh zakvasok pri silosovanii kormov. [**Use of bacterial fermentation in ensilage of fodders.**] *Zhivotnovodstvo*, 1955, No. 9, 83–84.

The use of bacterial cultures in the preparation of silage has proved its value as shown by results at several experimental stations. The cultures contained large amounts of lactic acid bacteria. The smell and quality of the silage were improved and in some cases there was direct evidence of increased production by cows and pigs given this silage.—H. Scherbatoff.

4211

SEREN'EV, V. M. and VIL'NER, R. A. Pitatel'nost silosa iz pochatkov kukuruzy. [**Feeding value of silage from maize cobs.**] *Zhivotnovodstvo*, 1956, No. 3, 77. [Inst. Zernov. Khozyaistva Nechernozemnoi Polosy.]

One hundred kg. ensiled cobs of waxy ripeness contained 65 feed units, *i.e.*, 3 times as much as in cobs ensiled at the milky stage.—H. Scherbatoff.

CULTURE OF MICRO-ORGANISMS FOR FOOD

4212

MOJONNIER, M. L., HEDRICK, L. R. and PORTER, T. **The microbiological assay of the amino acids of five genera of yeasts grown under controlled conditions.** *J. Nutrition*, 1955, **57**, 579–591. [Univ. Chicago, Ill.]

The amino acids of *Candida krusei*, *Pichia membranaefaciens*, *Saccharomyces carlsbergensis*, *Hansenula anomala* and brewer's yeast grown in a synthetic medium containing glucose and $(NH_4)_2SO_4$ as sources of C and N were estimated microbiologically. Total N in the first 4 ranged from 5·57 to 7·45 per cent., compared with 8·76 per cent. for brewer's yeast. The amino acids (18) accounted for 73 to 79 per cent. of the total N. All the yeasts contained the 8 essential amino acids and were relatively rich in lysine but poor in cystine and methionine. When KNO_3 replaced $(NH_4)_2SO_4$, *H. anomala* produced the same amount of protein but the amino acid composition was quite different.—A. Hepburn.

4213

VAVRA, J. J. and JOHNSON, M. J. **Aerobic and anaerobic biosynthesis of amino acids by bakers' yeast.** *J. Biol. Chem.*, 1956, **220**, 33–43. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

4214

GARRIDO, J. M. and WALKER, T. K. **Mycological formation of fat. 2. Synthesis of fat from various carbohydrates in surface cultures of *Aspergillus nidulans*, *Penicillium javanicum* and *Penicillium spinulosum* and the influence of the nitrogen source on the synthesis of fat from glucose.**

MURRAY, S. and WALKER, T. K. **3. Media conducive to formation of fat from sucrose by *Penicillium soppii* Zaleski in surface culture.** *J. Sci. Food Agric.*, 1956, **7**, 233–237 ; 237–240. [Div. Indust. Biochem., Fac. Technol., Univ. Manchester.]

See also Abst. 3332, Vol. 25 ; *J. Sci. Food Agric.*, 1954, **5**, 339.

2. By methods similar to those reported earlier the effects of different carbohydrates on fat production by moulds were studied. The best results were given by xylose, glucose, maltose and inulin. *Aspergillus nidulans* produced the greatest weight of fat from glucose and also the greatest amount of fat per g. sugar utilised. With xylose, *P. javanicum* gave the best result, with maltose, again *A. nidulans*. For all 3 moulds ammonium nitrate was the best source of N, though *A. nidulans* used $NaNO_3$ as successfully and urea slightly less well.

3. The growth of *Penicillium soppii* on inorganic media was improved by addition of maize steep liquor. With suitable media, mycelia were obtained with more than 40 per cent. fat and a production of 12·5 g. fat per 100 g. sucrose metabolised.

D. Duncan.

ENERGY VALUE, PROXIMATE PRINCIPLES AND INORGANIC CONSTITUENTS

GENERAL

4215

STROO, M., NUNNIKHOVEN, R. and WÖSTMANN, B. S. J. De aminozuursamenstelling van het gemiddeld dieet der Nederlandse bevolking. [**Amino acids of the average diet of the Netherlands population.**] *Voeding*, 1956, **17**, 132–136. [Nederlands Inst. Volksvoeding, Amsterdam.] English summary.

The composition of the average diet is taken as described by van der Rijst *et al.* (Abst. 876, Vol. 26). A corresponding mixture of foods was dried, hydrolysed with HCl and concentrated ; N was estimated by the Kjeldahl method and amino acids were separated by column chromatography by the method of Moore and Stein (Absts. 4469, Vol. 21 ; 3200, Vol. 25) as modified by Schram *et al.* (Abst. 44, Vol. 24). The result is shown in a table in terms of 23 amino acids together with the requirements of growing rats for 12 of them according to Rose *et al.* (Abst. 5101, Vol. 19) and to Williams *et al.* (Abst. 4768, Vol. 24), requirements for 8 of them of grown men derived from experiments in which N equilibrium was the criterion, to be doubled for safety according to Rose (Abst. 3891, Vol. 19), and intake of 10 amino acids in the United States per 100 g. dry diet, according to Block and Bolling (Abst. 3814, Vol. 23).

The Netherlands diet appears to supply less than rats need of several amino acids. It supplies much more than twice the need of human adults for N equilibrium, except for methionine. The United States diet, per 100 g. dry food, supplies more of all 10 amino acids shown. There is no evidence to show whether or not the amino acid composition of the Netherlands diet is optimum.

BASSIR, O. **Nutritional studies on breast milk of Nigerian women : some biochemical features of breast milk of Lagos women during the first year of lactation.** *J. Trop. Med. Hyg.*, 1956, **59**, 139–144. [Dept. Physiol., Univ. Coll., Ibadan.]

A milk sample compounded of 2 small samples taken before and after the 6 a.m. feed was obtained from 200 Nigerian mothers of healthy babies up to 12 months old. The samples were analysed for " cream ", lactose, N, Ca and P. The mean values for the 3 major constituents were similar to those reported for European and American series. The

individual variation was extremely large, *e.g.*, from 1·8 to 16·0 per cent. for "cream". The mean Ca and P contents, 20·3 and 9·54 mg. per 100 ml., were much lower than the usual published figures from European and American sources, but the mean Ca : P ratio was similar.—F. Hytten.

Pounden, W. D., Frank, N. A. and Krauss, W. C. **The resistance of milk samples to the activity of *Streptococcus agalactiae* as affected by pasture.**

Pounden, W. D., Frank, N. A., Brown, R. W. and Scherer, R. K. **The resistance of milk samples to the activity of *Streptococcus agalactiae* as affected by feeding silage.** *Amer. J. Vet. Res.*, 1956, **17**, 227–230; 231–234. [Dept. Vet. Sci., Ohio. Agric. Exp. Stat., Wooster.]

(a) The resistance of milk to *Streptococcus agalactiae* was judged by the amount of acid produced: the more acid, the less resistance. Milk was obtained from 3 groups of Holstein and Jersey cows, initially on the same feeds indoors. One group of 17 cows then went out on bluegrass pasture, one of 23 cows on legume and bromegrass pasture, and 14 cows were fed mainly on hay.

In both groups which went to pasture there was on the average an increase of 27 per cent. in acid production by *Str. agalactiae* cultures in the milk within a week. Experiments were repeated in the next 2 years, but the increases were smaller, 15·4 and 12·7 per cent. Sometimes the increase was maintained, sometimes it became less as the pasture season went on.

(b) When silage was given to cows which had been for 1½ years on hay and grain, acid production by *Str. agalactiae* in the milk increased, but this was not found when cows coming in from pasture were given silage. The interpretation of the results is discussed.—D. Duncan.

Marckmann, E. and Hingst, G. Erfahrungen und Ergebnisse einer einjährigen Untersuchung des Eiweissgehaltes der Milch von 1500 ganzjährig kontrollierten Kühen in Schleswig-Holstein. [**Tests and results of a one-year study of the protein content of the milk from 1500 cows recorded for a whole year in Schleswig-Holstein.**] *Milchwissenschaft*, 1956, **11**, 169–176. [Landeskontrollverband Schleswig-Holstein e.V.]

Milk accounts for 28 to 30 per cent. of farmers' income in Schleswig-Holstein. Of the yearly amount, 1·3 to 1·4 million metric tons, sold to dairies only 18 per cent. is sold liquid in Schleswig-Holstein and Hamburg; about 41,000 tons of butter and 11,000 tons of cheese are made yearly. Hence the protein content of the milk is important as well as the fat. From November 1953 to November 1954 it was estimated in samples obtained during 3-week milk recording from about 1750 cows [p. 170; about 2000 on p. 174, col. 1 and 1498 in col. 2] from 99 farms, some in the Eutin district and others from dry and marshy land in the Husum district, from herds of 20 and 11 cows on the average, mostly of the Black Pied Schleswig-Holstein breed, with some of the Red Pied Schleswig-Holstein and Angeln breeds.

Starting from work of Schulz and colleagues at Kiel [*Kieler Milchwirtsch. Forschungsber.*, 1953, **5**, 273], a routine method of formol titration was developed, by which, with the aid of automatic pipetting devices such as are used in routine estimation of milk fat by the Gerber method, protein could be estimated in 12 milk samples simultaneously and in 150 or even 200 daily. Much of the paper is devoted to the experimental details. An accuracy of 0·06 per cent. is claimed. Attempts were made to find a less dangerous preservative for the milk samples than corrosive sublimate with guaiacol, but neither potassium oxalate, hydrogen peroxide, sodium fluoride nor guaiacol alone proved satisfactory.

The results are appearing in full in publications of the *Deutsche Gesellschaft für Züchtungskunde*.

together with their biological and genetic implications. The most important are summarised at the close of this paper.

Significant positive correlations, from 0·5837 to 0·6852, were found between protein content and fat content ; as the fat content rises, the protein content rises one-third as rapidly on the average ; but the relation is not very close, for many cows show deviations from it. For a given fat content, a protein content higher by 0·25 per cent. may be expected in summer than in winter. The scatter of protein values was only about half that of fat values : protein ranged from 2·71 to 3·70 per cent. for 97·5 per cent. of the cows, and fat between from 3·01 to 5·00 per cent. for 97·6 per cent., and for 73·2 and 73·1 per cent., respectively, the protein and fat ranges were from 2·91 to 3·40 and from 3·41 to 4·40 per cent. Hence it is suggested [in the summary, not in text] that 2 to 3 times a month will suffice for testing milk to be used for cheese-making.

An effect of breed or locality on the protein-fat relation was not established. In mixed milk the protein content fell gradually from November to a minimum in April, rose suddenly when the cows went out to pasture, fell again to a second, less low point in July and rose again towards autumn. For fat content the minimum was in June. For cows at the stage of maximum yield (7- to 10-year-olds in the Eutin district) minimum fat occurred always during the time at pasture, *i.e.*, at different stages of lactation, but protein had a second, more pronounced, low point at the second to fourth test after calving. The fat content of milk from autumn calvers was 0·2 or 0·3 per cent. higher than from winter or spring calvers : for protein content the advantage of autumn calvers was about half that. Season of calving did not affect the protein-fat relation. Milk yield was highest in the sixth lactation ; the fifth and seventh were nearly as good ; it fell from the eighth onward. Fat and protein content were highest in the second and third lactation ; protein declined thereafter, but fat remained fairly constant until after the age of 10. Unlike fat, protein was nearly up to average in the first lactation. Except in extreme cases, yearly milk yield did not affect fat or protein content or the relation between them. From results for individual cows with the same yield and fat content of milk, it was found that the difference between actual and expected protein content was greatest from December to February, possibly owing to a decline in the quality of the feed in late winter ; but since in the June-July tests the protein content was highest in milk from autumn calvers and higher in winter calvers than in spring calvers, it may have been due to the cows' own need for more protein after calving and milking heavily.—W. M. Deans.

4224

DE VLEESCHAUWER, A. and HEYNDRICKX, G. V. Onderzoekingen over het verband tussen veten eiwitgehalte in melk. [**Relation between fat and protein content of milk.**] *Nederlands Melk Zuiveltijdschr.*, 1956, **10,** 10–17. [Leerstoel Technol., Rijkslandbouwhogesch., Ghent.] English summary.

Data on the composition of milk are not in agreement with reference to whether fat and protein or fat and particular components of the protein complex are correlated.

In this series fat and total protein were estimated in 28 samples, 9 of bulk milk and 19 of milk from individual cows, mostly of the red and white and black and white breeds. Total protein is (total N − N.P.N.) × 6·38. In 55 other samples, 8 of bulk milk and 47 from 28 cows individually, fat, total protein, casein, and albumin plus globulin were estimated by Rowland's methods (Absts. 12, 124, Vol. 8) and 4 fractions, probably α- and β-casein and β- and α-lactoglobulin, by electrophoresis by Tiselius's method. Between fat and total protein and fat and total casein there were significant correlations ($P = 0{\cdot}01$), but between fat and the casein fractions separately the correlation was less ($P = 0{\cdot}05$). It was also less but significant ($P = 0{\cdot}01$) for the albumin plus globulin and the sum of the α- and β-lactoglobulin fractions ; but with the lactoglobulin fractions separately there was no significant correlation.

STARY, Z. and CINDI, R. Über den Gehalt der Milchproteine an Galaktose und Hexosamin. [**The galactose and hexosamine content of milk protein.**] *Naturwissenschaften*, 1956, **43,** 179–180. [Inst. Biochem., Univ. Istanbul.]

Examination of casein hydrolysates by the method of Gurin *et al.* (*J. Biol. Chem.*, 1940, **133,** 467) showed that the hexose part of casein consists of galactose only. No hexosamine could be detected by the reaction with acetylacetone and dimethylaminobenzaldehyde. Whey protein, on the other hand, contained from 0·5 to 1·0 per cent. hexosamine, and about 5 per cent. hexose, mostly galactose. Cow colostrum contained more hexosamine and less galactose than the subsequent milk.—W. M. Deans.

BALIGA, B. S. and BASU, K. P. **Phospholipids in milk. 2. Variations in the lecithin, cephalin, sphingomyelin and total phospholipid contents of milk due to species, breed, season and stage of lactation.** *Indian J. Dairy Sci.*, 1956, **9,** 24–35. [S. Reg. Stat., Nat. Dairy Res. Inst., Bangalore.]

For method of estimation see Abst. 2720, Vol. 26.

2. The total phospholipin content of the milk of cows, buffaloes, sheep and goats, respectively, was 31·37, 21·03, 58·51 and 49·69 mg. per 100 ml., and the fat content 4·4, 6·7, 8·1 and 5·1. In all the species the proportions of lecithin, cephalin, and sphyngomyelin were similar, 30 : 45 : 25.

When different breeds of cow were compared, total phospholipins in the milk of Sindhi, Gir, Tharparkan and Ayrshire × Sindhi, respectively, were 31·55, 28·73, 33·71 and 31·39 mg. per ml., and fat 5·0, 4·5, 5·0 and 4·6.

Between sheep of different breeds a range from 51·78 to 67·38 mg. phospholipin per 100 ml. milk was found, and between milks from individual goats with wide differences in fat percentage even greater variation was found, from 25·84 to 82·38 mg. per 100 ml.

The effect of season was studied in cows and buffaloes. There was little effect in the former, any change found being no greater than might be due to individual variation. In buffaloes total phospholipins were low during the winter and high in the rainy season.

When the effect of lactation was studied, similar changes in cow and buffalo were found. Average values for colostrum phospholipins were from 45 to 50 mg. per 100 ml., but during the first 2 days they reached a peak of 60 to 70 mg. and fell quickly, then more slowly, till a value for normal milk of 30 mg. was reached by the 15th to 17th day. For 6 months values then remained constant. During the last months of lactation there was a steady rise to values similar to those of the later colostrum.—T. D. Bell.

ZEHREN, V. L. and JACKSON, H. C. **A survey of United States butterfat constants. 1. Reichert-Meissl, Polenske and refractive index values.**

KEENEY, M. **2. Butyric acid.** *J. Assoc. Off. Agric. Chem.*, 1956, **39,** 194–212 ; 212–225. [Dept. Dairy Food Indust., Univ. Wisconsin, Madison.]

1.2. The Reichert Meissl value, Polenske value, refractive index and butyric acid content were ascertained for over 500 samples of butter, obtained monthly for 1 year from 42 different sources in the U.S., covering 25 states with as wide a geographical range as possible. The results were analysed statistically.

The maximum average Reichert Meissl and Polenske values occurred during the late winter and the minimum average in midsummer. The maximum average refractive index was found in midsummer and the minimum average in late winter. The range of butyric acid values was from 9·6 to 11·3 mol. per cent. ; the arithmetic mean was 10·41 and the standard deviation 0·30 mol. per cent.—G. A. Garton.

4233

STADHOUDERS, J. and MULDER, H. **The composition of Dutch butter fat. 2. Seasonal variations in the saturated fatty acid composition of butter fat.** *Nederlands Melk Zuiveltijdschr.*, 1956,

10, 53–59. [Lab. Dairying, Agric. Univ., Wageningen.] Dutch summary.

For part 1 see Abst. 1562, Vol. 26.

2. The saturated fatty acid composition of 6 samples of Dutch butterfat was ascertained by the reversed-phase partition chromatographic method of Boldingh as described by van de Kamer *et al.* (Abst. 1435, Vol. 26).

In spring the butterfat contained much more butyric, caproic, caprylic and capric acid and more lauric acid than in autumn. The proportion of myristic and palmitic acids was greater in winter butterfat than in summer butterfat ; in spring the amounts of these acids suddenly fell. The amount of stearic acid was not correlated with that of any other higher fatty acid.—G. A. Garton.

4234

STEEN, K. Nyere undersøgelser over kendingstal for dansk smørfedt. [**Recent studies of values for Danish butterfat.**] *Forsøgslab. København. Beretn.*, 1956, No. 287, pp. 94. English French and German summaries.

Samples of butter were procured from the State Grading Centre (Statens Smørbedømmelser) which receives butter every week from 100 or more creameries. A compound sample was made each week and these totalled 367 [? 392] in the series between 1943 and 1951, 41 in 1953 and 47 in 1954. In addition, in 1953 and 1954, individual samples from 5 creameries chosen weekly at random totalled 212 and 237. Results in terms of Reichert Meissl, Polenske, saponification (Køttstorfer), Juckenack-Pasternak difference, and iodine number for part of the time, are reported in detail. Values for Polenske number corresponding to given Reichert Meissl values are given on p. 8 and means for the other numbers considered to be normal on p. 9. These standards are not Danish and are shown to be of doubtful validity in view of the changes in composition of butterfat which occur from one season to another and which have followed changes in feeding practice in recent years. According to these standards, of Polenske values in the series 1943 to 1951, there were, per cent., 43 above and 12 below normal, in 1953, 27 above and 51 below and in 1954 2 above and 70 below. The shift of Polenske in relation to Reichert Meissl values, which themselves appear to have risen, is attributable to the policy of increased use of home-grown feedingstuffs. Similar changes were found in the other values.

Data for iodine number of summer and winter butter are given separately. Softness of Danish summer butter, for instance in 1954, has been attributed to rise of iodine number, but the iodine number did not rise, so that the change must be in composition of pasture, or in the process of making butter. The iodine number of winter butter is low enough to account for brittleness and there are also complaints of " beety " taste. Both defects are explicable by increased use of home-grown feeds and reduction of the fat content of oilcakes and meals. Not only so, but iodine value of oilseeds and their products decreases from seed to cake to meal, which suggests that unsaturated acids may be removed before the more saturated.—I. Leitch.

4235

CERUTTI, G. and TAMBORINI, A. Sulle caratteristiche del burro attualmente in commercio. [**Characteristics of butter on the market.**] *Ann. Sper. agrar.*, 1956, **10,** 443–446. [Ist. Indust. Agrar., Univ. Milan.] English summary.

Of 95 samples of butter analysed, 40 were found to be adulterated with other fats. Thirty of these showed sufficient variation from normal standards to be illegal, the fats used, easily detectable, being from whale, dolphin, fish, or cocoa, or lard, palm oil or oleomargarine. In the other 10 the added fat was ewe's butterfat. The need for careful analysis and stringent application of the law is stressed.—T. D. Bell.

4236

WAUSCHKUHN, B. F.i.T.-Änderungen in Weichkäse während der Reifung. [**Changes in fat content of dry matter of soft cheese during ripening.**] *Milchwissenschaft*, 1956, **11,** 176–178. [Milchwirtsch. Lehranst., Hameln.] English and Spanish summaries.

A preliminary report on the fat content of the dry matter of small (80-g.) and normal-sized (125-g.) Camembert cheeses of nominal fat content 30 or 45 per cent., during ripening. The fat content first falls and then rises, but the curves vary so much with conditions that it is considered that standard curves should be established for different sorts and sizes of cheese. This would be of practical use in preventing the packaging and marketing of cheese too soon, *i.e.*, before it has reached its maximum fat content.—W. M. Deans.

4237

CERUTTI, G. and CRISTALLO, G. Sulle variazioni delle costanti chimico-fisiche e della composizione del grasso dei formaggi. [**Variations in the physicochemical constants and the composition of the fat of cheeses.**] *Ann. Sper. agrar.*, 1956, **10,** 439–442. [Ist. Indust. Agrar., Univ. Milan.] English summary.

The oleic acid content, Reichert Meissl Wollny number, Polenske number, refractometric index and peroxide number are tabulated for 30 samples of Italian cheeses. Four samples contained propionic acid and one *iso*valeric acid. The conditions governing production of these acids are to be studied.—D. Duncan.

HARPER, W. J. and LONG, J. E. **Italian cheese ripening. 4. Various free amino and fatty acids in commercial Provolone cheese.**

LONG, J. E. and HARPER, W. J. **5. Various free amino and fatty acids in commercial Romano cheese. 6. Effects of different types of lipolytic enzyme preparations on the accumulation of various free fatty and free amino acids and the development of flavor in Provolone and Romano cheese.** *J. Dairy Sci.*, 1956, **39,** 129–137 ; 138–145 ; 245–252. [Dept. Dairy Technol., Inst. Nutrit. Food Technol., Ohio State Univ., Columbus.]

For parts 1 and 2 see *Butter, Cheese and Milk Prod. J.*, 1952, **43,** (5), 24 and (8), 22.

4. The sources, type and principal organisms of the starters were recorded and are tabulated with descriptions of flavour and data for moisture and water-soluble N in 10 Provolone cheeses after ripening for 9 months under standard conditions. Free amino acids, estimated in water extracts, were qualitatively the same in all samples. Quantitatively, histidine, α-aminobutyric acid and threonine were present in small amounts only ; the amounts of the other acids varied greatly. Amino acids were not present in the same ratios as in the original casein. The amounts were not related to the type of rennet paste used but were related to the predominating organism, being higher with *Lactobacillus lactis* than with *L. bulgaricus*.

Free acetic, propionic and butyric acids were estimated ; the contents were not related to the type of starter but that of butyric acid was related to intensity of desired flavour. Twenty more commercial samples were analysed for butyric and glutamic acids only ; in these and in the 10 other cheeses the concentrations of these acids rose with the intensity of desired flavour and the ratio butyric : glutamic acid remained at about 1 : 2.

5. Samples from 14 Romano cheeses were analysed by the same methods as in part 4 and estimations also were made of fatty acids with more than 5 carbon atoms. Ages of the cheeses differed, their periods of ripening in months and numbers being 4 and 7 ; 10 and 3 ; 18 and 3 ; 26 and 1. The 4-month cheeses had been under standard conditions ; the others were commercial samples. In general the findings were similar to those for Provolone cheese but levels of free amino and fatty acids were higher in Romano cheese, possibly because the temperature during moulding is lower than that to which Provolone cheese is heated.

6. Eight vats of the same milk in one factory and with the same starter, *Lactobacillus bulgaricus*, were made, in pairs, into Provolone and Romano cheese. The type of enzyme differed for the pairs, being rennet extract alone or with a calf or kid glandular preparation or an imported crude rennet preparation from kids. Processing data are given. The cheeses were stored for 1 year under standard conditions and analyses were made generally at 1, 14, 30, 60, 90, 220 and 370 days.

In both types of cheese development of characteristic flavour was least with rennet extract alone ; flavour and butyric acid content were more pronounced and greater with the kid preparations than with the calf one. There was no relation between free amino acid content and the enzyme product used. The patterns of free amino acids were the same but concentrations were higher in Romano than in Provolone cheese.

The development of desired flavour was related to contents of both butyric and glutamic acid in Provolone but only to that of butyric acid in Romano cheese.—D. Harvey.

4239

HINTZ, P. C., SLATTER, W. L. and HARPER, W. J. **A survey of various free amino and fatty acids in domestic Swiss cheese.** *J. Dairy Sci.*, 1956, **39,** 235–244. [Dept. Dairy Technol., Inst. Nutrit. Food Technol., Ohio State Univ., Colombus.]

Swiss cheeses made under commercial conditions with the same starters were analysed after from 1 to 11 months. The findings are tabulated. Two amino acids not previously recorded in Swiss cheese were cysteic acid, in all 16, and taurine, in 10 of the samples. Valeric acid, also not recorded previously, was present in 6 of 7 cheeses tested for it. Before 3 months the glutamic acid content was low. There was some indication of a relation between the contents of proline and propionic acid ; if these were, respectively, below 2 and 5 mg. per g. cheese the rating for characteristic Swiss cheese flavour tended also to be low.—D. Harvey.

4240

SHARARA, H. A. **Retention of calcium and phosphorus in Egyptian Domiati cheese.** *Indian J. Dairy Sci.*, 1956, **9,** 17–23. [Fac. Agric., Univ. Cairo.]

Samples of Domiati cheese were prepared over a year from 10 lots each of cow's and of buffalo's milk. The average Ca content of the milks was 0·137 and 0·223 and of the cheese 0·588 and 0·624 g. per 100 g. ; corresponding values for P were 0·053, 0·102 and 0·144, 0·196 g. In the cheese the mean retention of Ca was for cow's milk 70·6 and for buffalo's milk 67·9 per cent., with corresponding values for retention of P of 48·9 and 49·0 per cent.

Vorkommen freier Aminosäuren und verschiedener Transaminasen in reifendem Sauermilchkäse. [**Biochemistry of cheese ripening. 17. Presence of free amino acids and of transaminases in ripening sour milk cheese.**]

SCHORMÜLLER, J. and HUTH, H. 18. Atmung und Gärung im Verlaufe der Reifung von Sauermilchkäse. [**18. Respiration and fermentation during the ripening of sour milk cheese.**] *Ztschr. Lebensmittel - Untersuch. Forsch.*, 1956, **103,** 291–305; 361–379. [Inst. Lebensmittelchem., Tech. Univ., Berlin-Charlottenburg.]

17. The problem of transaminases in ripening cheese (see part 11 of the series, *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1955, **100,** 200) was attacked again with a different method of analysis, described in detail, in which free amino-acids were separated and estimated by circular paper chromatography, generally with a 4 : 1 : 5 mixture of *n*-butanol, glacial acetic acid and water, with ninhydrin for detection. Isatin was a more sensitive detector for proline and hydroxyproline and for prolyl-peptides (see part 12, *idem*, p. 380), and diazotised sulphanilic acid for histidine and tyrosine. Comparison was with a standard mixture of 13 amino acids. Certain amino acids were not clearly separated by the above solvent; bands containing glutamic acid and threonine, or aspartic acid, glycine and serine, were separated by a 10 : 5 : 5 mixture of pyridine, *iso*amyl acetate and water, and this mixture, or a 25 : 5 : 5 mixture of *iso*propanol, glacial acetic acid and water, served to separate tyrosine and α-aminobutyric acid, or γ-aminobutyric acid and tryptophan, or valine and methionine. The separated acids were estimated by a modification of the method of Giri *et al.* (Abst. 41, Vol. 24) in which the ninhydrin-copper complex was measured photometrically.

When this method was applied to an ultrafiltrate of a 20 per cent. suspension of ripe cheese there was interference from lower peptides (see part 12), including leucylglycine and leucylglycylglycine, and to avoid this the ultrafiltrate was subjected to mild hydrolysis with HCl. (Further investigation of peptides is going on.)

All the main constituents of casein, namely, glutamic acid, proline, leucine, *iso*leucine, lysine, aspartic acid and valine, were found in fairly large amounts; but the leucines were plentiful only in the hydrolysates, which showed that in many (but not all) ultrafiltrates they were bound in peptides of low molecular weight. Only very small amounts of tyrosine, threonine and phenylalanine were detected, no arginine, and histidine only in traces; alanine and glycine were much more plentiful, so that the amounts in casein and the amounts of free amino acids by no means always conform. Only very small amounts of tryptophan and methionine were found and cystine and cysteine could not be detected. These results are mostly in agreement with earlier ones (Absts. 4263, Vol. 24; 220, Vol. 25; 2859, Vol. 26).

Attempts to isolate glutamic acid-aspartic acid transaminase were only partly successful. By estimation of glutamic acid by the method described above, transamination between α-ketoglutaric acid and 14 amino acids in presence of an active cheese suspension which had been centrifuged and dialysed to remove salts and free amino acids was investigated. Glutamic acid formed from peptides and proteins by proteolytic enzymes, or by transamination between α-ketoglutaric acid and amino acids set free by proteolysis, was allowed for by a blank experiment with α-ketoglutaric acid, cheese suspension and no amino acid. Transamination occurred with aspartic acid, and with methionine, leucine, *iso*leucine, valine and γ-aminobutyric acid to about half the extent, and with phenylalanine to a less extent; not with cystine, arginine, lysine, β-alanine or proline; α-aminobutyric acid and histidine gave doubtful results and require further investigation.

18. Respiration of a fine 10 per cent. suspension of cheese with *M*/15 Sörensen phosphate buffer, measured in a Warburg manometer at 37° C., was greatest between the 6th and 10th days of ripening and between *p*H 6 and *p*H 7·5. At *p*H 7·2 respiratory activity was greater in rind than in interior, and in unsalted curd than in normally ripening cheese; but, strange to say, addition of NaCl did not inhibit respiration. At the natural *p*H of the particular stage of ripening, the respiratory quotient was much the same for unsalted curd as for normal cheese, between 0·8 and 0·9; from the absence of extreme values it was concluded that under aerobic conditions decarboxylation does not occur. Respiration of washed suspensions was stimulated by L-glutamic acid, L-proline, L-lysine, DL-phenylalanine and DL-alanine (but 8 other amino acids from casein were without effect), and by glucose, DL-lactic acid, pyruvic acid, acetic acid and ethanol.

In normal cheese anaerobic fermentation set in about the 6th day and rose to the 10th day; it varied more with *p*H than did respiration, maximum at *p*H 6 to 7, but, unlike respiration, was unaffected by temperature. In addition to CO_2, hydrogen was produced, about a fifth as much.

The results are discussed at length. One practical conclusion is that sour milk cheese should not be wrapped in cellophane or other airtight material until respiration is maximum, or just after this.

W. M. Deans.

MAOLI, G. Contributo alla conoscenza della composizione chimica e del valore nutritivo della ricotta ottenuta dal siere di latte di pecora.

[Chemical composition and nutritive value of "ricotta" made from whey of sheep's milk.] *Ann. Sper. agrar.*, 1956, **10**, 565–576. [Ist. Sper. Zootec., Rome.] English summary.

Ricotta, or albumin cheese, is made by rapidly cooking the whey left after making cheese. Sheep's whey gives a better product than cow's and in Italy that from the Sopravissima breed is acknowledged the best. The original milk has 8·1 per cent. butterfat, and the residual whey 3·5 to 5·0 per cent., which is included, with the whey protein, in the ricotta.

Ten samples of ricotta were analysed. Average dry matter was 43·14, which was made up of crude protein 20·24, fat 71·11, ash 1·30 and lactose 7·20 per cent. The energy supplied by 100 g. fresh material was 330 Cal., 85 per cent. of which was from the fat, 11 per cent. from the protein and 4 per cent. from the lactose. Most of the protein was lactalbumin, with one-tenth as much lactoglobulin, and traces of N.P.N., and had a high biological value. The fat was high in caproic, caprylic and capric acids, but these did not impart any unwelcome flavour.—T. D. Bell.

Eggs

4243

MATSUDA, Y. and IWAMURA, I. **Chemical studies on the fertility and sex differences of eggs. 1. The ratio of arginine to tryptophane in fertilized and nonfertilized eggs of domestic fowl.** *Bull. Fac. Agric. Univ. Miyazaki*, 1956, **1**, 196–200. [Lab. Animal Feeding, Fac. Agric., Univ. Miyazaki.] In Japanese: English summary.

The percentage of arginine on a fresh weight basis in the fertilised germinal discs of 6 eggs from White Leghorn hens was 0·75 and from Barred Plymouth Rock hens 0·83. For tryptophan the values were 1·10 and 1·11. Corresponding values for other portions were: non-fertilised germinal discs 0·71, 0·81 and 1·07, 1·16; fertilised egg yolks 0·71, 0·87 and 1·04, 1·13; non-fertilised egg yolks 0·73, 0·83 and 0·98, 1·14. The arginine : tryptophan ratios in these 4 groups calculated from the above data were 0·71, 0·68, 0·73 and 0·74 [these differ slightly from the ratios given]. The arginine content of the acid hydrolysates of fertilised and non-fertilised germinal discs was 1·52 and 1·41 per cent.—A. Hepburn.

4244

RHODES, D. N. and LEA, C. H. **Composition of egg phospholipids.** *Nature*, 1956, **177**, 1129–1130. [Low Temp. Res. Stat., Downing St., Cambridge.]

Egg yolk phospholipins were selectively hydrolysed in the α′-position to yield lysolecithins by the action of snake venom; these compounds were found to have a residual unsaturation of about 0·15 double bond per molecule, indicating the presence in egg yolk of lecithins containing 2 unsaturated fatty acid residues in the molecule. The fatty acids of the lysolecithins were hydrogenated and found, by partition chromatography, to consist of palmitic acid 67 and stearic acid 33 per cent. Highly unsaturated lecithins were prepared by chromatography on silica columns and found to contain acids in the α′-position with an average unsaturation of 5 unconjugated double bonds per molecule; hydrogenation of these acids followed by chromatography showed that components of C_{20} and C_{22} chain length were present.—G. A. Garton.

Meat (All Kinds)

4245

ANDO, N. **Chemical studies on the beef of Korean cattle.** *Mem. Fac. Agric. Univ. Miyazaki*, 1955, **1**, 1–135. [Lab. Chem. Technol. Animal Products, Fac. Agric., Univ. Miyazaki.]

A study on 57 bulls, 11 cows and 12 bullocks is reported. Differences in composition of beef and visceral and external fat were investigated. Four cuts of beef were compared in each class of animal, the tenderloin, psoas major, loin, longissimus dorsi, fore shank, deltoideus and hind shank, biceps femoralis.

Significant differences were found between cuts in fat percentage and energy values, in both sexes being higher in the tenderloin. Fat and energy were highest in cows, lowest in bulls and intermediate in bullocks. The beef of young bulls 3 to 5 years old had more water and less fat and glycogen than that of bulls 6 to 10 years old. The range of age of the cows was only 7 to 11 years, and was too small to show clear differences. The beef of fat bulls had higher percentages of fat, protein and ash than that of medium or thin bulls.

A growth trial was made with bullocks castrated at 1, 2 or 3 years old, and intact bulls, all fattened for 310 days when they were 7 years old. Castration increased growth rate, improved efficiency and gave better carcase grades, the greatest improvement being after castration at 1 year old. In the bullocks the cut with the highest fat percentage was the loin.

Glycogen content of the muscle of bulls was not affected by site or standard of nutrition. In loin it was greatest in cows, intermediate in bullocks and least in bulls.

Digestibility of the protein of the beef of bulls was 95·85 per cent. and that of bullocks 96·13; these were not significantly different, and in neither class was there any difference between cuts.

Differences in distribution of N and total N were found due to sex, and to castration. Cows had higher total N, water-soluble N and amino N than bullocks, and bullocks more than bulls.

Visceral adipose tissue from the kidney, omentum and mesentery of bulls and cows and of external fat from the buttocks of cows were analysed. Great variation was noted between individual bulls. Of visceral adipose tissues, kidney fat had more fat and less water. External adipose tissue in cows had less fat and more water than kidney adipose tissue. The extracted fat of visceral adipose tissue had a higher melting-point and a lower iodine number than that of external adipose tissue from cows; the properties of visceral fat did not differ between sexes.—T. D. Bell.

4246

COVER, S., BUTLER, O. D. and CARTWRIGHT, T. C. **The relationship of fatness in yearling steers to juiciness and tenderness of broiled and braised steaks.** *J. Animal Sci.*, 1956, **15,** 464–472. [Texas Agric. Exp. Stat., College Station.]

The relationship of fatness to juiciness and tenderness in meat was investigated in samples from the carcases of 38 yearling Hereford and Hereford × Brahman steers. Fatness was determined by physical separation, visual assessment of marbling fat, and ether extracts of trimmed muscles; palatability scores for juiciness and tenderness were made on broiled and braised steaks from loin and bottom round.

The best correlation between juiciness and fatness was in broiled loin steaks and between tenderness and fatness in bottom round. Juiciness and fatness scores were more closely correlated with ether extract than with other measures of fatness. No correlation was high and although there was no doubt that fatness and eating quality were associated, variation in fatness accounted for no more than 30 per cent. of the variation in juiciness and only 10 per cent. of the variation in tenderness.—T. R. Preston.

4247

MILLER, M. and KASTELIC, J. **Chemical responses of connective tissue of bovine skeletal muscle.** *J. Agric. Food Chem.*, 1956, **4,** 537–542. [Dept. Home Econ. Res., Iowa Agric. Exp. Stat., Ames.]

This formed part of a thesis (Miller, Iowa State Coll., 1954). After a brief critical review of the literature, detailed studies of the connective tissue of beef muscle (semitendinosus and semimembranosus) are reported. The muscle was comminuted in a silent cutter and after extraction with a mixture of 0·6 *M* KCl and 0·03 *M* $NaHCO_3$, or with 0·1 *N* or *N* NaOH, stroma proteins were collected on glass wool. N was estimated by the micro-Kjeldahl method, and also calculated from hydroxyproline, estimated by the method of Neuman and Logan (Abst. 1335, Vol. 20). Digestion studies were made with papain or testicular hyaluronidase.

The more alkaline the extracting solution, the smaller the N content of the residue. The differing fractionations with KCl and NaOH, the differing absorption spectra of hydrolysates of the fractions, and the differing results of subsequent digestion with papain are shown in diagrams. The results are discussed and it is concluded that the traditional emphasis on the fibres, collagen and elastin, rather than the amorphous ground substance of mucopolysaccharides and complexes of these with proteins, does not really throw light on the nature of connective tissue or explain changes in tenderness of meat.—W. M. Deans.

ZIMMERMANN, W. Die Bestandteile des Schweineschinkens und ihre quantitativen Beziehungen zum Ganzen und untereinander. [**Components of the pig ham and their quantitative relations to the whole and to each other.**] *Züchtungskunde*, 1956, **28,** 212–219. [Inst. Tierzucht., Univ. Göttingen.]

The 250 pigs studied were of several breeds and were killed at 180 to 240, mean 210, days old. Liveweight was from 97 to 120, mean 108·8, and carcase weight from 78 to 98·5, mean 88·5 kg. All were from a testing station. The weight of the ham was from 9543 to 13,132, mean 10,431 g. The hams were dissected and their parts weighed separately.

There was a weak positive correlation, $r = 0{\cdot}378$, between carcase weight and weight of ham; the latter depended also on the type of pig. The total weight of the ham depended on both flesh and fat content, but less on bone and skin. There was a weak negative correlation, $r = -0{\cdot}358$, between flesh and fat. There was no correlation between external and internal fat. The total weight of flesh could be deduced with high probability from the weight of the gastrocnemius muscle.

The pig with a full-looking ham did not always produce qualitatively the best; there was often more meat in the leaner ham.—D. Duncan.

Fish

4250

KARKHANIS, Y. D. and MAGAR, N. G. **Component fatty acids in body fats of some marine fishes.** *J. Amer. Oil Chem. Soc.*, 1955, **32,** 492–493. [Inst. Sci., Bombay.]

The component fatty acids of 3 species of Indian marine fish, white pomfret (*Stromateus cinerus*), black pomfret (*Str. niger*) and pala (*Hilsa ilsha*), were found by the method of ester-fractionation. The saturated fatty acids of all 3 species consisted mainly of palmitic acid, with stearic and myristic acids; traces of arachidic acid were present in black pomfret and pala fats. About 32 per cent. (mol.) of the total acids of each fat was oleic acid. The amount of palmitoleic acid, 20 per cent. (mol.), in the acids of black pomfret fat was much greater than that found in the other fats. Polyunsaturated acids were present in black and white pomfret fats, but only in traces in pala fat.—G. A. Garton.

4251

KYTE, R. M. **Constituent fatty acids of salmon egg fat.** *J. Amer. Oil Chem. Soc.*, 1956, **33,** 146–149. [Fish. Products Lab., Ketchikan, Alaska.]

The constituent fatty acids in the egg fat from pink salmon (*Oncorhynchus gorbuscha*) were estimated by Hilditch's method. The percentages of C_{18}, C_{20} and C_{22} unsaturated fatty acids were 31, 31 and 15 with average unsaturation of 3·6, 7·3 and 11·8 hydrogen atoms. The alteration in fatty acid esters during vacuum distillation was calculated from the correlations of refractive index, carbon chain length and unsaturation given by Hammond and Lundberg (*J. Amer. Oil Chem. Soc.*, 1954, **31,** 427). The unsaturated fraction in the vacuum distillation was significantly altered by heat even in the first sub-fraction, and analysis by Hilditch's method gave low values for unsaturation and chain length.—A. Hepburn.

4252

MCBRIDE, J. and MACLEOD, R. A. **The sodium and potassium content of British Columbia sea foods. 2. Some commercially important fresh fish.** *Fish. Res. Board Canada, Progr. Rep. Pacific Coast Stat.*, 1956, No. 105, 19–21. [Technol. Stat., Vancouver, B.C.]

For part 1, dealing with canned salmon and tuna, see same journal, No. 101, 17.

2. In samples of the raw flesh of fresh spring salmon Na content ranged from 31·0 to 61·5 mg. per 100 g. and K from 320 to 470 mg. For coho, sockeye, pink and chum salmon the ranges were from 33·0 to 70·0 mg. for Na and from 340 to 485 mg. for K. For lingcod, graycod, halibut and herring the range for Na was from 48·0 to 83·5 mg. and for K from 355 to 485 mg. There was considerable variation between species, and also within species, according to the size of the fish.

J. S. Thomson.

4253

VARELA, G. and WOJCIECH, R. Sobre algunos procesos bioquímicos en la descomposición de la merluza ("*Merlucius merlucius*"). [**Some biochemical changes during decomposition of hake, *Merlucius merlucius*.**] *An. Bromatol.* 1956, **8,** 5–18. [Lab. Nutrición, Esc. Bromatol., Univ. Madrid.] English summary.

Fresh hake was bought in the Madrid market in slices of 500 to 750 g. The fish was analysed fresh or kept under different conditions before analysis.

Fresh hake contained 18·31 per cent. of dry matter, composed of protein 91·13, ash 6·81 and fat 1·56 per cent. When it was stored at 6° C. for 7 days the *p*H rose from 6·4 to 7·5, and dimethylamine N from 0·70 to 2·31 mg. per 100 g. fresh muscle, trimethylamine N from 9·48 to 37·71 and tyrosine from 18·08 to 40·08. Similar changes occurred under other conditions of storage. Dimethylamine N could be used as an index of decomposition. The form of the container had an important influence on keeping quality. The iodimetric test of Truttwin (Title 1554, Vol. 24) was much influenced by the degree of trituration of the sample.—D. Duncan.

4254

DA COSTA, A. and STERN, J. A. **The calcium and phosphorus contents of some foreign and domestic canned sardines.** *Food Res.*, 1956, **21,** 242–249. [Sch. Fish., Univ. Washington, Seattle.]

The sardine is not a particular fish; the term is applied to different small species of the genera Clupea, Sardinops and Sardina. This partly explains the wide range of Ca and P contents found in the literature, from which some are quoted. Ca and P contents are also affected by seasonal and physiological changes in the fish and still more by scaling of the larger fish or by removal of skin and bones.

Ash, Ca, P and Ca : P ratio are tabulated for 42 samples of canned sardines, representing at least 3 brands from each of the following regions (probable species in brackets): Portugal (*Clupea pilchardus*), Japan (*Sardinops melanosticta*), Norway and Sweden (*C. harengus* or *C. sprattus*), Maine, U.S. (*C. harengus*), California, U.S. (*S. caerula*); and also for tinned squid, anchovy fillets and tuna from Portugal and tuna from California. Ca was estimated by the A.O.A.C. micro-method (Abst. 3286, Vol. 22) and P by the methods of Fiske and Subbarow (*J. Biol. Chem.*, 1925, **66,** 378) and Lowry and Lopez (Abst. 1353, Vol. 16) in the fish drained of oil or tomato sauce.

Portuguese sardines in oil or tomato sauce were the best with Ca 580, 593 and P 624, 595 mg. per 100 g., respectively. Almost all the other kinds had only 2/3 as much Ca, or less, and 5/6 as much P, or less. Boneless sardines and particularly boneless and skinless sardines had much less Ca than whole sardines.

For whole sardines the Ca : P ratio was nearly unity for all regions but for skinless and boneless sardines it approached 1 : 6.

The other canned sea foods had about half as much P as sardines, and tuna and squid had little Ca.—W. M. Deans.

4255

WIERZCHOWSKI, J. Badanie i ocena krajowych pasztetów rybnych pod wzgledem zawartości niektórych składników odżywczych. [**Investigation and evaluation of fish pastes of Polish make with reference to the content of certain nutrients.**] *Rocz. Państwowego Zakł. Hig.*, 1955, **6**, 437–442. Russian and English summaries.

Tables are given of the results of analysis of 2 types of fish paste, made from fish liver or from minced fish.

The energy value of 100 g. fish paste was calculated with the coefficient 9·3 for fat and 4·1 for protein plus carbohydrate. The protein plus carbohydrate content was calculated by subtracting from the total mass the estimated contents of water, fat and ash. Fat was estimated by Gerber's method.

The 2 types of fish paste were found to differ considerably. For liver and minced fish pastes, respectively, the average protein content was 12·9 and 22·5 per cent. and the average fat content 37·4 and 22·3 per cent. The average energy values per 100 g. were about 425 Cal. and 280 Cal.

W. Z. Billewicz.

Other Types

4256

DE SIQUEIRA, R., PECHNIK, E., LOPES, N. and GUERNELLI, O. Pesquisas sôbre o sururu alagoano. [**Studies of *Mytilus mundahuensis*.**] *Arq. brasil. Nutrição*, 1954, **10**, 299–333. [Esc. Med. Cirurg., Rio de Janeiro.]

Mussels (sururu, *Mytilus mundahuensis*) were collected from the north side of a lake, at a mean depth of 2 m. They are sold cooked, pickled in vinegar, or shelled and sun-dried. The fresh mussels contained, per cent., moisture 62·8, protein 19·4, ether extract 2·3, ash 11·9 and other substances 3·6, Ca 0·14, P 0·28, Fe 0·006 and Si 0·38; vitamin A was not found, vitamin B_1 16 μg. per 100 g., riboflavin a trace and nicotinic acid 3300 μg. per 100 g. The nicotinic acid content was reduced in the pickled mussels. The dried flesh contained 64 per cent. protein. The mussel is thus a good source of protein, nicotinic acid and Fe.

The nutritive value of mussel protein in an experiment with rats was about equal to that of casein. The amino acids detected by paper chromatography were aspartic acid, glutamic acid, glycine, serine, threonine, alanine, arginine, lysine, tyrosine, tyrptophan, valine, phenylalanine, leucine, *iso*-leucine, methionine, cystine, histidine, proline and hydroxyproline.

The mussels could be collected in good quantities from a series of brackish lakes near the Atlantic coast of Brazil. They form an important part of the animal protein supply of the very poor inhabitants of the area. Production in 1952 was 1,074,600 kg. in the shell and 32,000 kg. meat.

Some methods of cooking the mussels are described.—D. Duncan.

CAMPEN, W. A. C. Het gehalte aan fytinefosfor in veevoeders. [**Phytin phosphorus in stock feedingstuffs.**] *Landbouwk. Tijdschr.*, 1956, **68**, 727–730. [Rijkslandbouwproefstat., Maastricht.] English summary.

Inorganic and phytin P are estimated together, after digestion of the sample in HCl, by precipitation as Ca salts, solution of the precipitate in mixed sulphuric, perchloric and nitric acids and estimation by the vanadium method or by colorimetry. Inorganic P is estimated separately in the original extract and deducted to give phytin P.

A table gives total, phytin, inorganic and undefined P in 44 feedingstuffs, most of them concentrates, and a second table compares the estimates of phytin P in 14 of these with values given by Common (Abst. 122, Vol. 10). There is no phytin P in potato and relatively little in beet pulp, 0·01 in a total of 0·08 per cent., or dried grass, 0·04 in 0·40; most cereals and oilcakes have from 60 to 80 per cent. of P as phytin P.—I. Leitch.

RÖSELER, M. Neue Untersuchungen über den Nährstoffgehalt einiger noch wenig gebräuchlicher Futtermittel (Phacelia, Melilotus albus, Kochia, Elodea canadensis). [**New studies of the nutrient content of some little-used feeds : *Phacelia, Melilotus albus, Kochia, Elodea canadensis.***] *Arch. Tierernährung*, 1956, **6,** 50–54. [Inst. Tierernährungslehre, Humboldt Univ., Berlin.]

Five samples of fresh *Phacelia tanacetifolia*, taken weekly from the end of May to the end of June, showed the following ranges : dry matter 14·75 to 30·26 per cent., containing crude protein 22·6 to 15·0, true protein 18·1 to 11·4, crude fat 3·0 to 4·8, crude fibre 14·5 to 23·2, ash 18·1 to 14·1, N-free extract 40·0 to 44·6 per cent. For 3 samples of *Melilotus albus* (white melilot), 2 in July and one from a second cut in September, the corresponding ranges were 15·25 to 17·54 ; 21·7 to 30·0, 16·4 to 19·5, 3·3 to 4·0, 20·8 to 27·0, 11·3 to 15·3, 35·5 to 28·5. These are compared with values in the literature and it is concluded that both would be useful as fodder plants.

A sample of *Kochia trichophylla* (summer cypress) a garden plant belonging to the Chenopodiaceae, had 18·36 per cent. dry matter, containing crude protein 21·2, true protein 15·0, crude fat 2·6, crude fibre 24·8, ash 16·8, N-free extract 34·8. Thus it resembles fodder plants, but cultivation and feeding trials are required.

For a sample of *Elodea canadensis* (Canadian water-weed), a fresh-water pest, the corresponding values were 16·59 ; 15·2, 14·3, 1·6, 9·6, 42·8, 30·9. Owing to the extraordinarily high ash content, much of it silicate, it is not likely that this plant will be useful for animal feeding.—W. M. Deans.

STEPURINA, Z. K. Dinamika proteina, mineral'nykh veshchestv i karotina v kukuruze v zavisimosti ot faz vegetatzii. [**Changes in protein, minerals and carotene content of maize in relation to stage of growth.**] *Zhivotnovodstvo*, 1956, No. 3, 78. [Stavropol'sk. Sel'skokhoz. Inst.]

The highest crude protein, 31·1 g., and carotene contents, 65 mg. per kg. green matter, were present in maize before flowering, at the stage of stalk formation. The Ca and P contents ranged from 1·28 to 1·69 and from 0·53 to 0·82 g. per kg. green matter, respectively, during the different stages of growth, being highest at the wax stage of the cobs. At all stages of growth there was more Ca than P, the ratio being of the order 2 : 1.

DÉVÉNYI, T. and SZÖRÉNYI, E. Artspezifität der Prolamine vom Gesichtspunkt der N-endständigen Aminosäuren. [**Species specificity of prolamines from the standpoint of N-terminal amino acids.**] *Acta physiol. hung.*, 1956, **9,** 301–308. [Biochem. Inst., Ungarisch. Akad. Wiss. Budapest.] Russian summary.

The findings of Deutsch (Abst. 1796, Vol. 25) that gliadin from wheat had phenylalanine as an N-terminal amino acid and that gliadin from rye had phenylalanine and glutamic acid were confirmed ; but no free N-terminal amino acid was found in gliadin from a rye-wheat hybrid or from *Agropyrum cristatum*, or in hordein from barley (*Hordeum vulgare*). Zein from maize had phenylalanine and threonine and avenin from oats had threonine as N-terminal amino acids.

W. M. Deans.

CHMIELNICKA, J. and MONIKOWSKI, K. Badanie nad rozmieszczeniem chloru w ziarnie pszenicy i żyta. [**Studies on the distribution of chlorine in wheat and rye grains.**] *Rocz. Państwowego Zakł. Hig.*, **6,** 461–467. Russian and English summaries.

To determine distribution of chlorine in wheat and rye, material for analysis was obtained by drilling the grain with dental drills varying in diameter, so that the substance analysed could be identified as belonging to different layers of the grain. It is admitted that this method is not perfect, since the grain is not perfectly cylindrical and therefore the first drilling will contain more substance near the crease than subsequent drillings, but the effect is considered too small to influence the results.

After dry ashing, chlorine was estimated by Roberts' method (H. F. Milton, "Methods of Quantitative Microanalysis", 1949, 182).

The chlorine content of the germ was estimated separately. Dental drills of 0·5, 1·0 and 1·5 mm. were used in turn and the grain was drilled lengthwise. Taking the whole grain as 100, the relative sizes of the layers were : wheat, layers 1–4, counting outwards from the centre, 12·8, 17·2, 40·0, 22·18 per cent., germs 7·82 per cent. ; rye, layers 1–4, 13·2, 15·9, 37·1, 24·5 per cent., germs 9·3 per cent. The chlorine content, in mg. per 100 g. dry substance, was found to be : wheat, layers 1–4, 6·3, 7·4, 6·7, 10·6, germs 2·5 ; rye, layers 1–4, 3·72, 12·9, 3·9, 9·3, germs 2·1. The percentage ratio of Cl to ash was found to be in wheat, layers 1–4, 9·6, 7·3, 0·89, 1·07, and in rye, layers 1–4, 5·18, 14·28, 0·71, 1·04. For the whole grain the proportions were 1·48 and 1·23 for wheat and rye, respectively. A table also is given showing percentage ash, percentage Cl and percentage Cl in 100 g. ash for different grades of wheat and rye flour. The results resemble those of the above analysis. [First row of col. 3 of this table (4) should read 1·23 per cent. Cl per 100 g. ash, not 1·74.]—W. Z. Billewicz.

Prokhorova, N. T. Soderzhanie letuchikh kislot v rzhanom khlebe kak pokazatel ego kislotnosti. [**Volatile acids in rye bread as an indicator of its acidity.**] *Vop. Pitan.*, 1956, **15**, No. 3, 26–30. [Otdel Gig. Pitan., Nauch.-Issled. Sanit.-Gig. Inst., Leningrad.]

Volatile acids were estimated in 22 samples of rye bread. They accounted for 40 to 50 per cent. of the total acidity. The total volatile acid was made up of acetic acid 37·8 to 68·4, propionic acid 28 to 52 and formic acid 1·16 to 10·7 per cent. The total volatile acid content was higher the sourer the flavour of the bread.—D. Duncan.

4271

Kulp, K., Golosinec, O. C., Shank, C. W. and Bradley, W. B. **Current practices in bread enrichment. Nutritive content of enriched bread.** *J. Amer. Dietetic Assoc.*, 1956, **32**, 331–334. [Amer. Inst. Baking, Chicago, Ill.]

In 255 samples of wrapped sliced enriched bread purchased in 52 cities in 39 states during 1952–54 moisture, protein, fat, ash, Ca and Fe were estimated by A.O.A.C. methods (Abst. 3286, Vol. 22), lactose by Munsey's method (*J. Assoc. Off. Agric. Chem.*, 1952, **35**, 697) and vitamin B_1, riboflavin and nicotinic acid by methods of the Association of Vitamin Chemists, Inc. (Abst. 2976, Vol. 21).

Average results on a 38 per cent. moisture basis were : protein 8·21, ash 1·90, milk solids calculated from lactose 2·59, fat 3·19 per cent., Fe 10·96, Ca 397·1, vitamin B_1 1·15, riboflavin 0·81 and nicotinic acid 10·56 mg. per lb. Average amounts of Fe and B vitamins exceeded the minima for enriched bread specified by the Food and Drug Administration, namely, 8, 1·1, 0·7 and 10·0 mg. per lb., respectively ; Fe was low in 4·7 per cent. of samples, vitamin B_1 in 24·5, riboflavin in 7 and nicotinic acid in 24·3, though many were only slightly below standard. Eighty per cent. of samples had from 7·5 to 8·5 per cent. protein and from 300 to 600 mg. Ca per lb. ; 0·8 and 15·6 per cent., respectively, had less. Seventy-five per cent. of samples had from 2·0 to 3·5 per cent. non-fat dried milk solids and 17·4 per cent. had less. More fat and milk solids and Ca and considerably more Fe and B vitamins were found than in studies made before 1941, when enrichment was recommended.—W. M. Deans.

Lunden, A. P. Undersøkelser over forholdet mellom potetenes spesifikke vekt og deres tørrstoff- og stivelsesinnhold. [**Specific gravity of potatoes and their dry matter and**

starch content.] *Forskning og Forsøk Landbruket*, 1956, **7**, 81–107. [Norges Landbrukshøgsk.] English summary.

The relations of dry matter and starch to sp. gr. in 1356 samples of potatoes of different varieties grown in different soils and under widely different weather conditions (1937 to 1947) are as follows:

$$Y = 17{\cdot}016 + 209{\cdot}038\ (X - 1{\cdot}0949),$$
$$Z = 24{\cdot}045 + 215{\cdot}732\ (Z - 1{\cdot}0949),$$

where Z=sp. gr. (Reimann's balance): Y= starch ("autoclave" method described by von Schéele *et al.*, *Nord. Jordbruksforsk.*, 1936, **17-18**, 17), and Z is dry matter (electric oven, 90° to 92° C. for 20 hr., 98° to 100° C. for 4 hr.). Correlation coefficients between sp. wt. and dry matter and between sp. gr. and starch were 0·969 and 0·945. In comparison with other data Norwegian potatoes have a high dry matter for the same sp. gr.—I. Leitch.

4273

LE TOURNEAU, D. **Carbohydrate components of the potato tuber.** *J. Agric. Food Chem.*, 1956, **4**, 543–545. [Dept. Agric. Chem., Univ. Idaho, Moscow.]

When potatoes (Russet Burbank) were extracted with hot 80 per cent. ethanol, sucrose, fructose and glucose were detected chromatographically in the extract. After further extraction with ether the dried ground residue was fractionated in different ways and found to contain, besides 80 per cent. starch, which was removed by hydrolysis with saliva, pectin, an araban-galactan soluble in 50 per cent. ethanol, hemicellulose and cellulose. The main sugars found on hydrolysis of fractions were arabinose and galactose.—W. M. Deans.

4274

MULDER, E. G. and BAKEMA, K. **Effect of the nitrogen, phosphorus, potassium and magnesium nutrition of potato plants on the content of free amino-acids and on the amino-acid composition of the protein of the tubers.** *Plant and Soil*, 1956, **7**, 135–166. [Agric. Exp. Stat., Groningen, Netherlands.]

Potatoes of 2 varieties, Noordeling and Voran, were grown in the years 1951 to 1954 on sandy, peaty soils originally low in one or more of N, P, K and Mg. The manurial treatments in kg. per ha. were (1) N as ammonium nitrate limestone 40 or 160, (2) P as superphosphate 0 or 300, (3) K_2O as potassium sulphate 0, 200 or 400, (4) MgO as magnesium sulphate 5 or 160, (5) K 400, N 150. In representative samples prepared after storage for 1 to 6 months from 25 tubers, water-soluble protein of about 90 per cent. purity was obtained by precipitation with salt, centrifuging, washing and drying, and was hydrolysed with 6 *N* HCl. Amino acids were estimated in the filtrate (soluble N.P.N.) and protein hydrolysate by the paper chromatography method of Thompson and Steward (Title 3040, Vol. 21), of which full details are given. The results are tabulated in g. amino acid per 16 g. amino acid N or g. per 100 g. protein (16 g. N), respectively, and also in mg. per 10 g. dry matter. Values are also given for the ratio protein N: soluble N.P.N. in 12 varieties, including the 2 mentioned, and for amino acids in the protein of crosses of *Solanum andigenum* or *S. demissum* with ordinary potatoes.

The amino-acid composition of potato protein (8 samples), in g. per 16 g. protein N, was glycine 5·5 ± 0·16, alanine 5·0 ± 0·29, serine 6·2 ± 0·30, cystine plus cysteine 0·9 ± 0·11, threonine 6·2 ± 0·21, valine 6·7 ± 0·18, methionine plus methionine sulphoxide 2·4 ± 0·19, leucines 16·5 ± 0·39, phenylalanine 5·2 ± 0·10, tyrosine 4·5 ± 0·22, proline 4·0 ± 0·21, tryptophan 1·9 ± 0·04, aspartic acid 9·5 ± 0·45, glutamic acid 9·7 ± 0·09, arginine 4·3 ± 0·37, lysine 4·2 ± 0·18, histidine 2·7 ± 0·11; ammonia 1·6 ± 0·03. On the whole these agree with values quoted from the literature.

Amino acid composition of potato protein, unlike protein content, was unaffected by the supply of N, P or K, and there was little evidence of varietal difference. Amino acid composition of soluble N.P.N. was affected by both fertiliser and variety. Amides formed a higher proportion of soluble N.P.N. in potatoes from soils high in N or low in P or K. There was no relation between the amounts of amino acids occurring free and those in the protein. Of some amino acids, free amino acids formed a considerable proportion of the total, *e.g.*, 30 to 50 per cent. for tyrosine, glutamic acid and arginine, and smaller proportions for valine, methionine and phenylalanine. An ample supply of N gave tubers containing from 30 to 40 per cent. more of almost every amino acid, owing to the effect on the protein content of the tuber, and tubers from plants deficient in P or K also had high contents of most amino acids.

As was found previously by Mulder (*Plant and Soil*, 1949, **2**, 59) K-deficient plants gave tubers with much tyrosine, which may cause blackening.

SPEIRS, M., MILLER, J., PETERSON, W. J., RIGNEY, J. A., MILLER, E. V., LUCAS, H. L., COCHRAN, F. D., REDER, R., CORDNER, H. B., O'DELL, G. V., FERNÁNDEZ, M. DEL C. C., RICHARDSON, L. R., WHITACRE, J., KAPP, L. C., BRITTINGHAM, W. H. and BEESON, K. C. **Influence of environment on the chemical composition of plants. 2. Variations in the composition of turnip greens with location, season, and concomitant environment.** *Southern Coop. Ser.*

Bull. No. 42, June 1955, pp. 123. [Puerto Rico Agric. Exp. Stat., Río Piedras.]

For part 1, a review, see Abst. 3366, Vol. 25.

2. A detailed account is given of an extensive investigation of turnip greens (leaves without midrib) of the Seven Top variety at 5 experimental stations in 4 southern states and Puerto Rico. At all but the last there were plots at 2 or 3 sites differing in soil type, and plants were also grown in pots of sand. Fertilising was uniform, except that at one station additional N was applied to ensure adequate growth, and cultivation was by the usual methods. From 1 to 3 sowings in rows 3 ft. apart were made in the spring and autumn of 1949, 1950 and 1951; plants were later thinned to about 3 in. apart. Samples were taken about 5 weeks after sowing and repeated weekly for 6, 4 and 2 weeks according to the sowing. Altogether about 1000 samples from field plants were analysed. Full details are given of methods of collecting soil and weather data and of sampling. Methods of estimating Ca, P, Mg, carotene, vitamin B_1, riboflavin and ascorbic acid have already been described (W. J. Peterson *et al.*, *Southern Coop. Ser. Bull.* No. 10, 1951). Na and K were estimated by flame photometer and Fe by the *o*-phenanthroline method as described by Sheets and Ward (Abst. 2331, Vol. 11). The basic data and the findings, on both fresh and dry basis, are presented in many tables and are analysed statistically. Portions have been published already (Ca and P, Abst. 122, Vol. 14; Fe, Abst. 1769, Vol. 18). Frequency distributions for the nutrients are shown graphically.

The all-over averages on a dry basis for plants grown in the ordinary way, with standard deviations, were: crude fibre 7·46 $\pm$ 0·83, ether extract 4·46 $\pm$ 1·38, total N 5·55 $\pm$ 0·99, P 0·575 $\pm$ 0·106, Fe 38·35 $\pm$ 17·17 per cent.; Ca 143·5 $\pm$ 29·3, Mg 35·8 $\pm$ 12·3, K 97·0 $\pm$ 29·4, Na 15·5 $\pm$ 11·3 m. equiv. per 100 g.; carotene 50·06 $\pm$ 12·87, ascorbic acid 1088 $\pm$ 170 mg. per 100 g.; vitamin B_1 1428 $\pm$ 332, riboflavin 2628 $\pm$ 570 μg. per 100 g. Values for plants grown in sand did not differ much from these except that Na was lower.

Analysis of variance showed that year, *i.e.*, weather, had a significant effect on dry matter and on crude fibre, ether extract, Ca, P, Mg, K and all vitamins but riboflavin, on both fresh and dry basis. Locality significantly affected P, Fe, K, Na and all vitamins but vitamin B_1. Soil type significantly affected N, all minerals and all vitamins but riboflavin. Differences between spring and autumn were mostly ascribed to weather, except for total N, carotene and riboflavin at some stations. Calendar date of sowing had little effect. The general conclusion was that organic constituents are affected chiefly by weather, inorganic by both soil and weather, and this was supported by comparison of plants grown in the field and in pots of sand.—W. M. Deans.

Legumes

Petronici, C. Contributo alla conoscenza del metabolismo azotato nelle piante: variazioni degli aminoacidi liberi e totali nella fava (*Vicia faba major*) durante il ciclo vegetativo. [**Nitrogen metabolism of plants: variations in free and total amino acids in the bean (*Vicia faba major*) during the cycle of growth.**] *Ann. Sper. agrar.*, 1956, **10,** 841–855. [Ist. Chim. Agrar., Univ. Palermo.] English summary.

The composition of bean plants was studied at 7 stages of growth, from plants 10 cm. tall to the stage of ripe seeds. Dry matter, total and soluble N, free amino acids and total amino acids after hydrolysis were studied.

The free amino acids found were aspartic acid, glutamic acid, alanine, asparagine, phenylalanine, leucine, lysine, proline, serine, tyrosine, threonine, valine and probably γ-aminobutyric acid. After hydrolysis glycine, cystine or cysteine and an unidentified amino acid were found also.

The variations with growth of the plant are shown in tables and in graphs for individual amino acids.—D. Duncan.

Learmonth, E. M. **Soya in the field of nutrition. A review of existing knowledge.** *Chem. and Indust.*, 1956, No. 18, 360–367. [British Soya Products, Ltd., London, E.C.3.]

4278

Gutiérrez Rojas, D. Contenido de aceite y proteina y respuesta al abonamiento de ocho variedades de soya. [**Oil and protein content and relation to fertilisers of eight varieties of soya.**] *Acta agronom., Columbia*, 1955, **5,** 211–221. English summary.

The yield and composition of the 8 varieties of soya bean tested were not significantly affected by fertilising with urea, dicalcium phosphate or KCl separately or in combination. The yields ranged from 568 kg. per plaza (6400 sq.m.) of the variety Hawkeye to 1809 kg. of Aksarben. The oil content ranged from 18·72 per cent. in Aksarben to 24·19 in Mammoth yellow; the latter gave the highest yield of oil, 423 kg. per plaza. The protein content ranged from 37·45 per cent. in Acadian 36 to 44·12 per cent. in Acadian 292; the protein yield per plaza is not given for Acadian 292, but for Aksarben, with 41·77 per cent. protein, the yield per plaza was 756 kg. Oil contents were more variable than protein contents, so total protein yield was closely related to total grain yield, but total oil yield was not.—D. Duncan.

4279

KROBER, O. A. **Methionine content of soybeans as influenced by location and season.** *J. Agric. Food Chem.*, 1956, **4**, 254–257. [Field Crops Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Urbana, Ill.]

Samples of 14 varieties of soya bean grown in from 12 to 18 localities in the United States in 1950, 1951 and 1952 were combined by variety and by locality and methionine was estimated in the protein by an adaptation of the chemical method of Horn *et al.* (Abst. 41, Vol. 17). The results were analysed statistically.

Seasonal differences were slight except in late-maturing varieties. Three-year averages ranged from 1·31 to 1·58 per cent. of the protein. Location differences were significant only among intermediate-maturing varieties, though there was a tendency for the methionine content to be higher in crops grown further south. Varietal differences were more important than either. Dunfield and related strains, and Clark, a Lincoln × Richland cross, were consistently good ; since the last surpassed its parents, it should be possible to improve the methionine content of soya beans by breeding.

Values for some varieties agreed closely with those found microbiologically by Alderks (*J. Amer. Oil Chem. Soc.*, 1949, **24**, 126).—W. M. Deans.

SMITH, D. G. and YOUNG, E. G. **The combined amino acids in several species of marine algae.** *J. Biol. Chem.*, 1955, **217**, 845–853. [Maritime Reg. Lab., Nat. Res. Counc., Halifax, Canada.]

Seaweeds were air-dried and ground and extracted with 75 per cent. ethanol. N and amino acids were estimated, the latter by paper chromatography of acid hydrolysates. Values are tabulated for *Fucus vesiculosus*, *Ascophyllum nodosum*, *Chondrus crispus*, *Rhodymenia palmata* and *Ulva lactuca*. In the first 4 species the N estimated in protein, free amino acids, peptides, organic bases, purines and pyrimidines accounted for 90 to 96 per cent. of the total N, but in *Ulva* only 80 to 86 per cent. of the total N was accounted for, and some peculiar form of N may be present. Amino acid N made up from 79 to 89 per cent. of the total N in the hydrolysate. Citrulline and ornithine were identified in the hydrolysate from *Chondrus*, but not in the other species. *Chondrus* was rich also in arginine. The composition of *Rhodymenia* and *Ulva* was similar, but differed from that of the brown algae.—D. Duncan.

Pasture, Hay and Silage

4289

HEINRICHS, D. H. and CARSON, R. B. **Chemical composition of nine grasses at six stages of development.** *Canad. J. Agric. Sci.*, 1956, **36**, 95–106. [Canada Dept. Agric., Ottawa.]

The grasses studied were smooth bromegrass (*Bromus inermis*), Russian wild ryegrass (*Elymus juncans*), Mandan wild ryegrass (*E. canadensis*), Fairway crested wheatgrass (*Agropyron cristatum*), Summit crested wheatgrass (*A. desertorum*), intermediate wheatgrass (*A. intermedium*), tall wheatgrass (*A. elongatum*), streambank wheatgrass (*A. inparium*) and green stipagrass (*Stipa viridula*). The grasses were analysed at 6 stages of growth: early leaf, shot blade, flower, mature seed, late autumn and the following spring, in the years 1951–52 and 1952–53. Crude protein, N-free extract, ether extract, ash, crude fibre, lignin, Ca and P were estimated.

Between species and between stages of growth there were significant differences in protein, N-free extract, ether extract, ash, crude fibre and lignin. There was also a difference between years. Protein in all was lower in 1952 than in 1951. Russian wild ryegrass was the best in both seasons, and maintained its protein content in the last cut better than the other grasses. Streambank wheatgrass also maintained its protein content well, but its initial value was lowest.

N-free extract was higher in 1952 than in 1951 in all and varied inversely with protein: bromegrass was exceptional, being high in both. The 2 grasses which maintained protein content were correspondingly lower in N-free extract at the later stages of cutting.

Ether extract was higher in 1951, and was higher in streambank wheatgrass than in the others at all stages.

Crude fibre was higher in 1952 than in 1951, but only in the early stages: this was related to the different growth induced by different weather in the 2 years. Bromegrass and Russian wild ryegrass were low in fibre at the later stages. Lignin, estimated in 1951 only, was related to the habit of growth; grasses which formed few stems and more basal leaves had a low lignin content.

Up to the mature seed stage the Ca : P ratio was good. After this stage the ratio was too wide, the best being in Russian wild ryegrass, tall and streambank wheatgrasses and green stipagrass, which had ratios of 5 or 6 : 1.—T. D. Bell.

SULLIVAN, J. T., PHILLIPS, T. G., LOUGHLIN, M. E. and SPRAGUE, V. G. **Chemical composition of forage grasses. 2. Successive cuttings during the growing season.** *Agronom. J.*, 1956, **48**, 11–14. [U.S. Reg. Pasture Res. Lab., State Coll., Pa.]

2. The results of plot experiments in 1950 and 1952 with Alta fescue, bromegrass, Kentucky bluegrass, orchardgrass, reed canarygrass, redtop,

timothy and tall oatgrass, systematically treated with N and cut at grazing height from 4 to 8 times during the season, are tabulated or shown graphically. Methods of analysis were as before (Title 4748, Vol. 25).

Alta fescue, Kentucky bluegrass, orchardgrass, reed canarygrass and tall oatgrass had crude protein contents ranging from 17·72 for Alta fescue to 18·58 for reed canarygrass and were significantly richer in protein than the 3 other species. Reed canarygrass and tall oatgrass were low in crude fibre, cellulose and lignin; orchardgrass was high in these and in ether extract and minerals. Kentucky bluegrass was low in ether extract, minerals and moisture and high in lignin. Correlations between constituents were not high, except that between crude fibre and cellulose, + 0·974; the regression equation, from 329 samples, was

$$y = 1{\cdot}694 + 0{\cdot}9318\,x,$$

where y = crude fibre, x = cellulose. Orchardgrass gave the highest annual yield of dry matter. Yields of dry matter decreased at successive cuttings. Crude protein remained steady until autumn, when it rose. Ether extract also rose in autumn. Cellulose, crude fibre and lignin were highest at the second cutting, at a time of long daylight; the first two decreased steadily thereafter, but lignin not till autumn. All the changes with time of year were small.—W. M. Deans.

HARBERTS, C. L., IMMINK, H. J. and DEIJS, W. B. Het chlorophylgehalte van gras in de loop van het weide-seizoen. [**Chlorophyll content of grass in the course of the pasture season.**] *Centraal Inst. Landbouwk. Onderzoek, Overdruk* 277, 1954 (1955), 228–230. English summary.

Chlorophyll is broken down, during digestion, to phaeophytin, which forms highly stable complexes with Cu; this might explain why Cu may be retained during stall feeding and lost at pasture. Chlorophyll a and chlorophyll b and phaeophytin were estimated by the method of Arnon modified as described in *Versl. Centraal Inst. Landbouwk. Onderzoek*, 1953, p. 168 and that of Joslyn and Mackinney (*J. Amer. Chem. Soc.*, 1938, **60,** 1132).

The first samples of grass taken in early May had less chlorophyll, 11·2 and 10·1 mg. per g. dry matter, in proportion to crude protein, 28·6 and 27·1 per cent., than later samples. The correlation coefficient between chlorophyll and crude protein contents for the 35 later samples was 0·88 ± 0·04. There was no seasonal change in that relation, except for the first samples, and none in the ratio of chlorophyll a to chlorophyll b, which varied between 3·3 to 2·8. Free phaeophytin varied between 0·5 and 1·1 mg. per g. dry matter without relation to season.—I. Leitch.

4292

DEIJS, W. B. Enkele gegevens over het nitraatgehalte van ruwvoedermiddelen. [**Some data on the nitrate content of roughages.**] *Centraal Inst. Landbouwk. Onderzoek, Overdruk* 212, 1953 (1954), 153–154. English summary.

Data are reported for samples from ordinary farms and a farm intensively fertilised with N as follows, in that order and per cent. of dry matter: fresh grass 63 and 40 samples, crude protein 20·2 and 22·5, nitrate as KNO_3 0·40 and 0·95; hay 11 and 30 samples, crude protein 14·7 and 20·8, KNO_3 0·29 and 1·02; grass silage 4 and 10 samples, crude protein 15·0 and 17·4, KNO_3 0·19 and 0·56; artificially dried grass, 11 and 3 samples, crude protein 18·0 and 21·1, KNO_3 0·47 and 1·52. I. Leitch.

A study of strains and the effect of fertilisers at two stations with some data on composition.

4294

GERI, G. Contributo alla conoscenza della composizione chimica e del valore nutritivo dei foraggi maremmani. [**Chemical composition and nutritive value of forages from the Maremma.**] *Ann. Sper. agrar.*, 1956, **10,** 577–618. [Lab. Zootec., Univ. Florence.] English summary.

Lucerne, sainfoin, bird's foot trefoil and cocksfoot pastures and natural pastures were analysed at different stages of growth. Natural pastures were better than leys as sources of fodder. The digestible protein content decreased and crude fibre content increased with advancing maturity. Ether extract and ash contents were not affected by the age of the plant. The P content of the plant was directly related to the available P_2O_5 in the soil.

Maturity affected the digestible protein content more than the nutritive value and hence the nutritive ratio was wider. As a whole the Maremma pastures investigated compared favourably with similar crops reported in the literature. The procedures are reported in detail, and results are tabulated.—T. D. Bell.

4295

WALKER, T. W., ADAMS, A. F. R. and ORCHISTON, H. D. **The effect of levels of calcium sulphate on the yield and composition of a grass and clover pasture.** *Plant and Soil*, 1956, **7,** 290–300. [Canterbury Agric. Coll., N.Z.]

Calcium sulphate as gypsum was applied to plots of sandy loam soil which had received also triple superphosphate at 100 lb. per acre. The gypsum was applied at 25, 50, 100 and 200 lb. per acre and the area was sown with a mixture of legumes. Plant and soil analyses were made 6 months later.

In comparison with the plot given no gypsum, large and significant increases were found in yield of clovers and of grasses. Total N was increased from 12 to 52 lb. per acre, and most of the increase was obtained with 50 lb. gypsum. The increase of N percentage in clover was twice that in grass. P was not much affected, but Ca was slightly increased by gypsum. Inorganic S remained low, but total S increased appreciably. More S was taken up by grass than by clover. It is concluded that the value of the gypsum was in the S content and that in South Island there are large areas where application of S is needed to promote fixation of N by legumes.—D. Duncan.

4296

LAZAR, V. A. and BEESON, K. C. **Mineral nutrients in native vegetation on Atlantic Coastal Plain soil types.** *J. Agric. Food Chem.*, 1956, **4,** 439–444. [U.S. Plant, Soil and Nutrit. Lab., Agric. Res. Serv., Ithaca, N.Y.]

Co, Cu, Mn, Ca and P were estimated in samples, mostly leaves, taken at different times in 1952 and 1953 from 5 browse or forage plants growing on six ½-acre plots of differing soil type on cut-over forest land, and in samples of the soil, at different places in North and South Carolina (at one place the forage was known to be too low in Co and Cu for cattle to survive). For methods, see Beeson, *J. Assoc. Off. Agric. Chem.*, 1953, **36,** 405 and Absts. 1883, Vol. 13 and 4515, Vol. 21. The results were analysed statistically and are shown for all plots in tables and for the plot known to be deficient also in graphs, and are discussed at length.

Swamp blackgum (*Nyssa sylvatica* var. *biflora* (Walt.)) and pepperbush (*Clethra alnifolia*, L.) were high in Co compared with the other 3 plants; about ½ lb. dry leaves of either from a Co-deficient area, along with the other browse and forage, would supply the minimum daily requirement of cattle. Cu did not vary much; blackgum and sweetbay (*Magnolia virginiana*, L.) were highest. Pepperbush was high in Mn; next came blackgum. No plant contained much P. Pepperbush was high in Ca. In most plants Co and Ca increased with maturity and Cu and P decreased. It was considered that blackgum leaves could serve as an indicator of the mineral content of forage as typified by broomsedge (*Andropogon glomeratus*, Walt.) except for Ca; 2 leaves per plot would suffice for Co and Cu, 5 for P and Mn. Although the Co content of the soil bore some relation to that of the plants, the relation was not close enough for the former to be used as a test of the adequacy of forage.—W. M. Deans.

MILLS, C. F. **Studies of the copper compounds in aqueous extracts of herbage.** *Biochem. J.*, 1956, **63,** 187–190. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Electrodialysis of aqueous extracts of freeze-dried herbage in a 4-compartment cell showed that although some Cu was present as the free ion or as positively charged complexes, most of it was present as neutral or anionic complexes. On the addition of radio-active $^{64}Cu(NO_3)_2$ the readiness of the water-soluble components of herbage to form complexes with Cu^{2+} was demonstrated. After incubation of the herbage extract with pepsin the Cu complexes were stable in the presence of a cation-exchange resin at *p*H above 2·5, but decomposed appreciably below *p*H 2·0.

BRZAC, T. Ekonomsko značenje primorske zajednice *Carex humilis-Centaurea rupestris*. [**Economic importance of the littoral association of *Carex humilis* with *Centaurea rupestris***.] *Vet. Arhiv*, 1956, **26,** 63–78. English and German summaries.

Typical hays from the natural forage investigated had dry matter 90·94 to 91·56, crude protein 7·27 to 8·86, N-free extract 47·64 to 53·78, ash 5·64 to 6·42, ether extract 3·04 to 3·44 and fibre 21·29 to 26·10 per cent. There were over 30 species in the association, some of them poisonous to stock. Only 6 species individually represented more than 5 per cent. of the total weight, and together those species represented 65 per cent. of the total. Analyses of the separate species, their

relative value as cover, and persistence are presented in tables. By virtue of its feeding value, and dominance due to covering capacity and persistence, *Carex humilis* is the most important species. There are other good species, from the feeding point of view. Improvement of the hay can be achieved only by sowing seeds of these species so that they will overcome the undesirable species. (From English summary.)—T. D. Bell.

4301

FRENCH, M. H. **The nutritive value of East African hay.** *Empire J. Exp. Agric.*, 1956, **24,** 53–60. [Joint Animal Indust. Div., E.A.A.F.R.O.]

Crude protein of 10 hays studied ranged from 3·7 to 9·2 per cent. of the dry matter, with a wide variation in digestibility from 30 to 60 per cent., which was related to species but not to stage of maturity. N-free extract ranged from 40 to 45 per cent., with digestibility 44 to 70 per cent., and crude fibre from 32·5 to 43·5 per cent., digestibility 52 to 65 per cent. In the more mature herbage digestibility of crude fibre was greater than that of N-free extract.

The more stemmy species were inferior to the others in both digestible crude protein and N-free extract. Of the others, the starch equivalent was comparable to that of temperate European hays, but the digestible crude protein content was lower. T. D. Bell.

HADORN, H. and SUTER, H. Über die Analyse und Zusammensetzung von Rohkaffee verschiedener Provenienzen. [**Analysis and composition of raw coffee of differing origin.**] *Mitt. Geb. Lebensmittel. Hyg.*, 1956, **47,** 33–51. [Lab. VSK, Basle.] French and English summaries.

Raw coffee beans from 4 regions were ground in a ball mill and analysed exhaustively by methods similar in principle to those of Slotta and Neisser (*Ber. Deutsch. Chem. Gesellsch.*, 1939, **72,** 126). Full details are given. The results are tabulated. Percentage ranges were for water 6·15 to 8·15, total lipids 10·95 to 16·40, total protein (minus trigonellin and caffeine) 10·11 to 11·29, water-soluble protein 5·23 to 5·65, caffeine 0·99 to 1·99, trigonellin 0·74 to 1·03, chlorogenic acid 4·58 to 5·74, sucrose 5·30 to 8·15, total ash 4 14 to 5·02, water-soluble minerals 0·89 to 1·93. An error was found in the balance drawn up by Slotta and Neisser: owing to incomplete extraction they underestimated the substances soluble in water. The present authors failed to account for about 10 per cent. of these, which may consist of organic acids and their salts and perhaps higher carbohydrates and tannins.—W. M. Deans.

4306

CERUTTI, G., CERUTTI, L. and TAMBORINI, A. Sul contenuto in ferro, bromo e piombo dei vini italiani. 1. [**Iron, bromine and lead in Italian wines. 1.**] *Ann. Sper. agrar.*, 1956, **10,** 451–454. [Inst. Indust. Agrar., Univ. Milan.]

1. The Fe, Pb and Br contents of 40 samples of wine known to be pure were estimated by methods described. The highest value for inorganic Br was 0·5 mg. per litre: no organic Br was detected. Up to 0·9 mg. Pb per litre was found, but most samples contained none. The Fe content ranged from 1 to 23 mg. per litre.—T. D. Bell.

4307

VITAGLIANO, M. I costituenti minerali del vino. [**The mineral constituents of wine.**] 2. Il ferro. [**2. Iron.**] 3. Lo zolfo. [**3. Sulphur.**] *Ann. Sper. agrar.*, 1956, **10,** 659–668; 711–719. [Ist. Indust. Agrar., Univ. Naples, Portici.] English summary.

2. Samples of wine and of the must from which it was fermented were analysed. The Fe content of the musts did not exceed 12 mg. per litre when only moderate pressure was used; when continuous and excessive pressure was applied values as high as 22 mg. per litre were obtained. The Fe content of the wines ranged from 2 to 114 mg. per litre. In ideal conditions of production, where pressure was not excessive and wooden vats were used for fermentation and maturing, there was little increase in Fe contents of must and wine. The great increases were caused by contamination from the equipment used, the worst being vats of cement.

An Fe content of more than 22 mg. per litre of wine gave a product that became cloudy on exposure to air. It is advocated that equipment in

the wine industry should be overhauled and renewed to eliminate the sources of contamination with Fe.

3. Inorganic and organic S were estimated in musts and wines. Inorganic S values, expressed as K_2SO_4, ranged from 0·12 to 0·43 g. per litre must in 25 samples analysed. Organic S ranged from 14 to 30 mg. per litre, slightly higher in black than in golden grapes. In 49 wines the inorganic S, as K_2SO_4, showed great variation, from 0·26 to 2·92 g. per litre, and 10 per cent. of the samples exceeded the legal limit of 1·5 g. per litre. The high S content was due to excessive use of SO_2 in the process of wine-making. Only a small portion of the organic S was present as methionine, and investigations on the form in which it is embodied are in progress.—T. D. Bell.

PLACIDI, L. and LARRE, J. Affection du poulet simulant la variole dans un élevage industriel (déficience alimentaire). [**Disease of poultry resembling fowlpox in a commercial breeding farm: a nutritional deficiency.**] *Rec. Méd. vét.*, 1955, **131,** 1108–1110.

On a large commercial chicken farm, 7022 chickens aged from 3 to 8 weeks died in 8 months. Those that survived remained in poor condition. The disease appeared in chicks a week old. The lesions were on the head and beak, and resembled those of fowlpox (*epithelioma contagiosum*). An epidemic of infectious disease was presumed, but after exhaustive investigation the idea had to be abandoned. An experiment was then made in which, at the same time, 80 of the chicks received the diet customary on the farm and 120 received a poultry food known to be highly satisfactory. The result was unequivocal. The second group remained well; the first group sickened but recovered when transferred to the good diet. The deficiency was considered to be multiple, but no further effort was made to find out its exact nature.

BURGER, M., HEIN, L. W., TEPLY, L. J., DERSE, P. H. and KRIEGER, C. H. **Vitamin, mineral, and proximate composition of frozen fruits, juices and vegetables.** *J. Agric. Food Chem.*, 1956, **4,** 418–425. [Wisconsin Alumni Res. Found., Madison 5.]

Eight vitamins, 6 minerals and 5 proximate constituents were estimated, and energy values calculated, for 14 frozen fruits, 7 frozen juices and 30 frozen vegetables produced by more than 150 freezing plants in the United States and Hawaii, and the results are tabulated. There were 796 sets of samples and 27,562 individual packages from 2 consecutive seasons. The packages were taken at statistically predetermined intervals to ensure representative sampling with regard to such variables as weather, variety, harvesting, processing, packing and grade. Citrus juices, almost all fruits and most vegetable products contained good quantities of ascorbic acid. Many products contained little sodium.—A. Hepburn.

VITAMIN A

4312

AMES, S. R. and HARRIS, P. L. **Slope-ratio liver storage bioassay for vitamin A.** *Anal. Chem.*, 1956, **28,** 874–878. [Res. Labs., Distillation Products Industries, Div. Eastman Kodak Co., Rochester, N.Y.]

Practical details are given of an improved and standardised modification of the liver-storage type of biological test.

Male rats were depleted of vitamin A, but not so far that disease was produced, and were divided into 5 groups of 10. One group was given in 3 days a standard preparation of vitamin A providing 1000 I.U.; another group was given a total of 2000 I.U. over the 3 days. Two groups were given the test material, in amounts estimated spectrophotometrically to provide about 1000 and 2000 I.U. per head. One group, the negative control, was given no vitamin A. Forty-eight hr. after the last dose the rats were killed, and the livers were kept frozen till analysed. Each liver was analysed separately. It was ground with anhydrous sodium sulphate, and vitamin A was extracted at room temperature with 100 ml. ether and estimated with the Carr Price reagent. The negative control group provided a common base line for testing the linearity of the responses. If the responses were linear within statistically accepted limits, the slopes of the response curves for the test material and standard were compared by a method that is explained. An example is worked out in detail.

When several compounds of vitamin A were tested by the storage method and by a standard growth method, the agreement was good. A value for the within-group precision of the storage method was calculated from the pooled results with 16 groups of rats. The mean standard error so calculated was 2·9 per cent. and is discussed. The method is much more rapid than the growth method and does not demand complete depletion of the rats. The response, in terms of the amount of vitamin A found in the liver in relation to that given, was linear over a dose range of from 500 to 10,000 I.U. The mean of 67 per cent. so recovered is higher than that usually recorded in the literature. The possible significance of such a high response is discussed.—V. H. Booth.

4313

LAGONI, H. and WORTMANN, A. Eine einfache quantitative Methode zur Bestimmung von Vitamin A and β-Carotin in Fetten und Ölen. **[Simple quantitative method for estimating vitamin A and β-carotene in fats and oils.]** *Milchwissenschaft*, 1956, **11,** 206–208. [Physik. Inst., Bundesforschungsanst. Milchwirtsch., Kiel.] English, Spanish and French summaries.

The method, developed from a qualitative one previously described (*Milchwissenschaft*, 1955, **10,** 360), was based on plate chromatography. Aluminium oxide, 5 to 7 g., was distributed uniformly over a glass plate 15 cm. square, and a drop of the sample or a dilution of it in groundnut oil was placed on the plate. The chromatogram was developed with light petroleum. β-Carotene formed an orange-yellow ring. The process was repeated with successive known dilutions as long as the characteristic ring could be seen. In the conditions used by the authors, this amount corresponded with 0·05 μg. carotene. Vitamin A could be estimated at the same time unless carotene was present in excess, by exposing the chromatogram to the light from a mercury vapour quartz lamp or, more sensitively, by spraying with the Carr Price reagent; the limiting amount of vitamin A was 0·06 μg. in oily solution. Annatto (bixin) and similar pigments did not interfere; if dimethylaminoazobenzene (butter yellow) was present, the plate had to be treated first with H_2SO_4 (45 per cent.). The method is claimed to be suitable for recording variations in the vitamin A content of butter with the feeding of the cows or during storage, and for controlling the carotene and vitamin A content of margarine.

W. M. Deans.

4314

GADE, E. T. and KADLEC, J. D. **Rapid estimation of vitamin A using a surface active agent.** *J. Agric. Food Chem.*, 1956, **4,** 426–427. [The Borden Co., Special Products Div., Elgin, Ill.]

The method of estimating vitamin A has been used for the analysis of chicken livers and of powdered preparations for infant feeding. Samples with a surface-active agent, which was a mixture of Triton X-100 and sodium tripolyphosphate dissolved in aqueous methanol, were extracted in one step with a mixture of light petroleum and ether, the extracts were purified chromatographically and the vitamin was estimated with the $SbCl_3$ reagent and an Evelyn photo-electric colorimeter. Extraction took 25 min. and several samples could be run simultaneously. Feed supplements containing *N*, *N'*-diphenyl-*p*-phenylenediamine and fortified with vitamin A embedded in a matrix were washed with ether. With 6 replicate samples of an infant food fortified with vitamin A palmitate, there was recovery of between 92 and 100 per cent. Comparison with methods that involve saponification showed good agreement of the results for each of the materials examined.—I. M. Sharman.

4315

DI CELSO, P. M. Illustrazione di un metodo rapido per la determinazione del carotene nei foraggi e nei mangimi. [**Rapid method for estimating carotene in fodders and foods.**] *Ann. Sper. agrar.*, 1956, **10,** No. 2, *Suppl.*, li-lv. [Ist. Sper. Zootec., Rome.] English summary.

Samples not exceeding 2 g. of fresh grass or 1 g. of dry forage or other material were triturated with quartz powder and extracted with methanol and benzene. The solvents were separated and the benzene fraction was saponified with alcoholic KOH in 90 per cent. ethanol. The benzene layer was again separated and washed first several times with methanol and then with 90 per cent. ethanol. The carotene was separated from the benzene extract by column chromatography and estimated in a Beckman spectrophotometer. Estimations by the method took only half an hour.

D. Duncan.

4316

OGDEN, R. L. **Effect of added fats and oils on carotene stability in dehydrated alfalfa meal during storage.** *J. Agric. Food Chem.*, 1956, **4,** 428–431. [Dept. Biochem. Nutrit., Univ. Nebraska, Lincoln.]

Animal fats and vegetable oils of several types were added to dehydrated alfalfa meal, which was then stored at 40° C. When only 40 per cent. of the carotene remained in untreated samples, carotene was estimated in the treated samples. The percentage remaining was called the carotene retention index. A value above 40 was evidence that the fat had protected the carotene.

The retention index of linseed, walnut, olive and some other vegetable oils was below 40. Cocoa butter, soya bean oil and refined maize oil had values slightly above 40. Beef tallow, pork lard, and mutton tallow had values at or near 60. Several other oils had little effect. In general, animal fats improved retention, but vegetable oils gave less protection or none or were harmful. Free fatty acids were estimated in each fat and oil. In general those with a high index had low free fatty acid values, and those with an index below 40 had high values. Retention was improved by treating oils with alkali to remove free fatty acids. Retention of carotene was improved by increasing the amount of animal fat added to the meal up to about 5 per cent., but with more than that there was little further effect. Oils or fats are applied to meal to reduce its dustiness, and, for that purpose also, proportions greater than 5 per cent. do not produce much further improvement. Five per cent., therefore, is about the highest proportion that is economically advantageous. The response to a given fat or oil was quantitatively different for different alfalfa meals, for which a possible explanation is discussed.—V. H. Booth.

BÄCK, K. **Effect of some metal ions on the stability of natural vitamin A.** *Acta chem. scand.*, 1956, **10,** 334–335. [Royal Inst. Technol., Stockholm.]

After metal ions had been removed from fish liver oil concentrates containing about 100,000 I.U. vitamin A per g., by percolation of a solution in propanol through a cation exchanger, solutions of metal chlorides in absolute ethanol were added to the samples to give final concentrations of 2 per cent. ethanol and 1, 10 and 100 p.p.m. of metal ion. Samples were stored in vials at 34·5° C. for different times, after which vitamin A was estimated spectrophotometrically. Typical curves are presented to show destruction of the vitamin relative to time of storage in the presence of aluminium ions. Ratios of the times for destruction of 50 per cent. of the vitamin A in oil containing 100 p.p.m. of metal ions, to those for the same loss from oil containing no metal ion were 0·5 for Al, 0·5 for Cu, 0·2 for Fe, 0·4 for Ni, 0·7 for Sn and 0·8 for Zn.—I. M. Sharman.

MATZKO, S. N. and ZHMEIDO, A. T. Periodichnost vvedeniya kak faktor, vliyayushchii na potrebnost v vitamine A. [**Vitamin A requirement as influenced by periodicity of administration.**] *Dokl. Akad. Nauk SSSR*, 1956, **106,** 367–369. [Nauch.-Issled. Inst. Vitaminol., Minist. Zdravookhran. SSSR.]

Male rats, one month old, in groups of 20 or 21 were kept, first on diets containing sufficient vitamin A to prevent signs of deficiency but allowing no storage and during the experiment on stock diet without vitamin A.

Groups 1 to 4 were given vitamin A daily, 1·3, 2·6, 5·1 or 10·3 μg., respectively; group 5 at weekly and group 6 at fortnightly intervals were given the equivalent of 5·1 μg. vitamin A daily.

In the first 4 groups increase of weight rose with the amount of vitamin A given.

In group 5, given vitamin A at weekly intervals, weight gain was as good as that in group 3; group 6, given vitamin A at 2-week intervals, put on less weight than group 3, but more than group 2.

In another series rats were given 1·3, 2·6, 5·1, 10·3 and 21 μg. vitamin A daily. Weight gain increased with increasing amount of vitamin A up to 10·3 μg.; the group given 21 μg. showed no further improvement. It is therefore concluded that a dose of 10 μg. fully covered the requirement and that the minimum physiological daily requirement is between 5 and 10 μg.

The general conclusion is that administration of vitamin A at weekly intervals did not affect the requirement, but that administration at intervals

of 2 weeks increased the requirement by half. That administration of vitamin A at intervals did not cause a spectacular increase of requirement is explained by the ability of the organisms to store large quantities of vitamin A in the liver.—F. Billewicz.

SHELDON, H. and ZETTERQVIST, H. **Experimentally induced changes in mitochondrial morphology: vitamin A deficiency.** *Exp. Cell. Res.*, 1956, **10,** 225–228. [Dept. Anat., Karolinska Inst., Stockholm.]

Specimens of corneal epithelium were taken at intervals from mice maintained for 250 days on a diet deficient in vitamin A. Light and electron microscopy of the corneal epithelium of 15 clinically ill animals showed keratinisation of superficial layers as histological evidence of vitamin A deficiency. The electron microscope showed that the basal cells of the epithelium contained many large mitochondria of normal appearance, and the cells of the most superficial layers contained few mitochondria. The cells in the intermediate layers of the keratinising epithelium showed many mitochondria with distorted internal structure and having dense areas within the matrix. It is suggested that vitamin A deficiency changes the metabolic pattern of the mitochondria so that there is accumulation of the dense substance which has hitherto been referred to as "keratohyaline", but whether the keratohyaline granules "actually stem from interference with normal mitochondrial metabolism" may require other methods to determine.—M. H. Pierce.

4320

SHELDON, H. and ZETTERQVIST, H. **An electron microscope study of the corneal epithelium in the vitamin A deficient mouse.** *Bull. Johns Hopkins Hosp.*, 1956, **98,** 372–405. [Dept. Anat., Karolinska Inst., Stockholm.]

Studies were made with the light and electron microscope of the corneal epithelium of mice deprived of vitamin A. The light microscope revealed keratinisation of the epithelium, with cornification and loosening of the outer layers. Keratohyaline granules were present in the cells of the intermediate and superficial regions, but the basal cells were apparently normal. Electron micrographs showed that in the basal cells the mitochondria were often arranged around the nucleus, which was frequently invaginated on the circumference and variegated in appearance. Granules were seen in the intermediate and superficial regions. Free and phagocytised bacteria were found occasionally in the loosened outer layers of the keratinised epithelium.—T. Moore.

SRÉTER, F. Adatok a karotinháztartás és az ásványi anyagforgalom összefüggéséhez. [**Relation of carotene to mineral metabolism.**] *Rep. Fac. Animal Husb., Hung. Univ. Agric. Sci.*, 1955, **1,** No. 10, 3–15. [Inst. Physiol., Univ. Agric. Sci., Budapest.] Russian, German and English summaries.

In 10 Hungarian spotted cows studied in 1954, about 1 g. carotene, given in the form of carrots, caused a transient rise of serum Ca, but there was no change when $CaCO_3$ was given. On another farm there was no rise in serum Ca after carotene, and in another test with Brown Swiss cows the rise occurred after 60 hr. In horses, also, carotene raised both serum Ca and inorganic P after 24 hr. (From English summary.)—D. Duncan.

4322

NERURKAR, M. K. and SAHASRABUDHE, M. B. **Metabolism of calcium, phosphorus and nitrogen in hypervitaminosis A in young rats.** *Biochem. J.*, 1956, **63,** 344–349. [Biol. Div., Dept. Atomic Energy, Govt. India, Indian Cancer Res. Centre, Parel, Bombay 12.]

Male rats from 6 to 7 weeks old were fed on a synthetic diet deficient in vitamin A and all received vitamin supplements including 100 I.U. vitamin A. After 10 days the amount of vitamin A was increased to 40,000 I.U. daily for 10 days, followed by a curative period of 14 days during which the intake of vitamin A was reduced to that given during the preliminary period. Metabolism experiments showed that the net retention of calcium during the preliminary period was about 65 per cent. of the intake; it fell rapidly during the period of high dosage to a negative value of 21 per cent. on the 8th day. During the curative period retention rose steadily to 53 per cent. Phosphorus metabolism gave a similar picture, with about 60 per cent. retained during the preliminary period, a fall to — 82·2 per cent. on the eighth day of high dosage and a rise to 57·2 per cent. at the end of the curative period. For nitrogen the net retention was about 80 per cent. during the preliminary period, — 51·7 per cent. on the 8th day of high dosage and 72·1 per cent. at the end of the curative period. Excess of vitamin A reduced food intake, and there was loss of weight with skeletal fractures and haemorrhages in the young rats. The concentration of Ca and inorganic P in the blood showed no change. Changes in composition of the bones were small, so that the loss of Ca and P was probably by thinning of the bones. Estimation of vitamin A in the liver showed absorption to be poor when the amount given was far in excess of the normal requirement.—I. M. Sharman.

MOURIQUAND, G., ROLLET, J., EDEL, V. and CHIGHIZOLA, R. Avitaminose et hypervitaminose A du pigeon. Identité de leur séméiologie oculaire. [**Lack and excess of vitamin A in the pigeon. Identity of their eye signs.**] *C.R. Acad. Sci.*, 1955, **241,** 348–350.

For earlier work see Absts. 4219, Vol. 18 ; 328, Vol. 24.

When pigeons were given vitamin A, 5000 I.U. daily, no eye change was seen and bodyweight and flight were unaffected ; index of chronaxie rose in the period from the 19th to 29th day and then returned to normal. When a larger amount of vitamin A, 25,000 I.U., was given the index fell to a very low value and between the 50th and 60th days there appeared in the eye signs of vitamin A excess which were similar to those produced by vitamin A deficiency. The view is held that deficiency or excess of the vitamin gives rise to the same pathological state.—D. Harvey.

4324

MOURIQUAND, G., ROLLET, J., EDEL, V. and CHIGHIZOLA, R. Sur la phase inapparente de l'hypervitaminose A. [**The concealed phase of vitamin A excess.**] *C.R. Soc. Biol.*, 1955, **149,** 1989–1991.

When pigeons were given daily doses of 25,000 I.U. vitamin A, vestibular chronaxie was slightly increased and later returned to normal. With 50,000 I.U. the index of chronaxie fell to very low values. The change preceded the appearance of the ocular signs of vitamin A excess which have already been described as resembling those of xerophthalmia (see preceding Abst.).—T. Moore.

MAYFIELD, H. L. and ROEHM, R. R. **The influence of ascorbic acid and the source of B vitamins on the utilization of carotene.** *J. Nutrition*, 1956, **58,** 203–217. [Dept. Home Econ. Res., Montana State Coll. Agric. Exp. Stat., Bozeman.]

Young rats in 20 groups with 4 males and 4 females in each were given a diet deficient in vitamin A until they showed signs of deficiency. One group was killed at that stage and vitamin A was estimated in the liver and kidneys. Groups 1 to 4 inclusive were given 30 μg. carotene, groups 5 to 10, 60 μg. and groups 11 to 19, 120 μg., daily for 14 days. Rats in the 3 sets of groups were given 0, 25, 50 or 75 mg. ascorbic acid daily, and those in groups 8, 9, 10, 14, 15 and 16 received B vitamins from a test diet in which 5 per cent. of a synthetic vitamin mixture was substituted for 8 per cent. of brewer's yeast. After 14 days of supplementary feeding the animals were killed and vitamin A was estimated in the liver and kidneys.

With 30 μg. carotene the average amount of vitamin A in the liver and kidneys of the females was 46·5 μg. for those receiving no ascorbic acid, 64·9 μg. for those receiving 35 mg. and 46·2 μg. for those receiving 50 mg. Corresponding values for the males were 52·0, 38·0 and 34·6.

The liver and kidneys of the females receiving 60 μg. carotene and 0, 25 or 50 mg. ascorbic acid had an average content of 90·8, 111·0 and 79·8 μg. vitamin A ; the values for the males were 102·3, 76·1 and 74·4 μg. When B vitamins were given instead of yeast the values for the females were 121·6, 144·3 and 117·3 μg. and for the males 113·4, 106·5 and 103·0 μg.

When 120 μg. was the carotene supplement with 0, 25 or 50 mg. ascorbic acid, the average vitamin A content of the liver and kidneys of the rats receiving yeast was 161·2, 175·1 and 185·3 μg. for the females and 131·8, 134·1 and 154·7 μg. for the males. The corresponding values for the animals receiving the synthetic vitamin mixture was 201·1, 200·0 and 225·0 μg. for the females and 178·9, 182·0 and 195·5 μg. for the males.

When 0, 50 or 75 mg. ascorbic acid was given with the supplement of 120 μg. carotene and yeast from a different source, vitamin A in the liver and kidneys of the females amounted to 194·2, 225·5 and 209·9 μg. and of the males to 185·7, 202·7 and 182·0 μg.—R. J. Ward.

4326

MAYFIELD, H. L. and ROEHM, R. R. **Carotene utilization as influenced by the addition of vitamin B_{12} to diets containing yeast or a synthetic vitamin mixture.** *J. Nutrition*, 1956, **58,** 483–493. [Dept. Home Econ. Res., Montana State Coll. Agric. Exp. Stat., Bozeman.]

A previous study (see preceding Abst.) had suggested that diets containing a mixture of synthetic vitamins allowed better utilisation of carotene than diets containing yeast. Rats were depleted of vitamin A and then given 60 μg. carotene daily with diets containing one of 4 different yeasts with or without vitamin B_{12}, or a mixture of synthetic vitamins. The vitamin B_{12} content of the yeasts estimated by microbiological methods varied considerably. The effect of carotene on growth and on storage of vitamin A in the liver was least with the yeast of lowest vitamin B_{12} content. Storage of vitamin A by rats given synthetic vitamins but no vitamin B_{12} was like that of rats given yeasts of moderate vitamin B_{12} content. Vitamin B_{12} added to the diet with a yeast of low vitamin B_{12} content improved growth and storage of vitamin A. No improvement occurred when vitamin B_{12} was added to the synthetic vitamin mixture, and more nicotinic acid added to the synthetic mixture did not

affect storage of vitamin A. There appeared to be substances in yeast, other than vitamin B_{12}, which were concerned in the utilisation of carotene by the rat.—A. M. Copping.

McGillivray, W. A., Thompson, S. Y. and Worker, N. A. **Further studies on the metabolism by rats of intravenously administered aqueous dispersions of carotenoid pigments.** *Brit. J. Nutrition*, 1956, **10**, 126–134. [Dept. Biochem., Massey Agric. Coll. (Univ. New Zealand), Palmerston North.]

For earlier work see Abst. 312, Vol. 26.

Rats deficient in vitamin A were given intravenously 250 or 35 μg. carotene in Tween 40, and 2 hr. later the values for vitamin A alcohol in the plasma in μg. per 100 mg., and for total vitamin A in the liver in μg., had increased to 66 and 3·7 or 36 and 3·2 compared with values in untreated rats of 21 and 1·6. After injection of 25 μg. into younger rats with lower reserves the corresponding values were 32 and 1·4 compared with 11 and 0·5 in untreated rats. In rats with greater reserves of vitamin A and injected with 250 or 35 μg. carotene, values in the plasma were 33 or 22 and for untreated animals 21.

Lycopene, xanthophyll, zeaxanthin and cryptoxanthin in amounts from 175 to 250 μg. had no effect on the vitamin A content of the plasma and liver of rats partly deficient in vitamin A, but a larger dose of cryptoxanthin given by mouth raised the values in plasma and liver. When 300 μg. α- or β-carotene was injected the amounts of vitamin A alcohol 24 hr. later in the plasma were 20 or 29 and in the liver 15·8 or 25·8 ; in untreated rats corresponding values were 15 and 1·0. Retinene was rapidly utilised, since half an hour after injection of 400 μg. the value for vitamin A in the plasma had risen to 27 and in the liver to 109. After 24 hr. the value in the plasma was 17 and in the liver 161. Groups of thyroidectomised, hyperthyroid and untreated rats, all partly deficient in vitamin A, had similar values in the blood and for liver storage of vitamin A 24 hr. after injection of carotene. Animals rendered hypothyroid by treatment with thiouracil showed an increase in liver storage from 12·3 to 18·7, 24 hr. after injection. When 400 μg. carotene was injected intravenously into rats deficient in vitamin A from which the liver had been removed, the value for vitamin A in the plasma rose from 10 to 57 after 5 min. and was 50 after 30 min.—R. J. Ward.

4328

Worker, N. A. **The effect of complete hepatectomy on the utilization by rats and rabbits of intravenously administered aqueous dispersions of carotene.** *Brit. J. Nutrition*, 1956, **10**, 169–175. [Dept. Biochem., Massey Agric. Coll. (Univ. New Zealand), Palmerston North.]

Thirty minutes after 320 μg. carotene in Tween had been injected intravenously into rats partly deprived of vitamin A, the average vitamin A alcohol content of the plasma in μg. per 100 ml. rose from 13 to 42. After a similar injection, plasma vitamin A alcohol in rats from which the liver had been removed rose from 10 to 49 after 10 min. and was 29 after 15 min. and 45 after 30 min. In rats given the injection of carotene after removal of the liver and viscera, the plasma value for vitamin A alcohol rose from 10 to 40 after 15 min. In rabbits from which the liver had been removed vitamin A alcohol in the blood plasma fell by a maximum of 27 μg. per 100 ml. after injection of distilled water or Tween ; it rose by about 10 μg. per 100 ml., 2 hr. after injection of 920 μg. carotene into such rabbits.—R. J. Ward.

Potter, L. M., Bunnell, R. H., Matterson, L. D. and Singsen, E. P. **The effect of antioxidants and a vitamin B_{12} concentrate on the utilization of carotenoid pigments by the chicks.** *Poultry Sci.*, 1956, **35**, 452–456. [Dept. Poultry Sci., Storrs Agric. Exp. Stat., Conn.]

For 4 weeks chicks were given a semi-purified diet low in vitamin A, supplemented with carotene in alfalfa meal to give the equivalent of 300 or 1200 U.S.P.U. vitamin A per lb. ration, and with or without 0·0125 per cent. N,N′-diphenyl-*p*-phenylenediamine (DPPD) or 2 : 6 di-*tert.*-butyl-4-methylphenol (BHT). With both amounts of carotene DPPD considerably increased the concentration of vitamin A and carotenoids in the plasma and liver ; BHT gave smaller increases. In a second experiment lasting 9 weeks, 12 mg. vitamin B_{12} per ton, in a practical diet containing 5 per cent. alfalfa meal, did not consistently increase vitamin A and carotenoids in the plasma and liver, but did greatly increase carotenoids in the skin. DPPD added to that diet increased only slightly the storage of vitamin A and carotenoids but DPPD and vitamin B_{12} together increased storage substantially.—E. M. Cruickshank.

Massonet, R. Activité antixéropthalmique des chromatoprotéides de crustacés administrés au rat blanc carencé en vitamine A. [**Antixerophthalmic activity of chromoproteins of crustacea given to white rats deficient in vitamin A.**] *C.R. Soc. Biol.*, 1955, **149**, 1971–1976. [Lab. Chim. Biol., Fac. Méd., Algiers.]

Solutions in physiological serum of chromoproteins from crustacea were injected by the

intraperitoneal route into albino rats deprived of vitamin A and showing xerophthalmia. Those treated with an extract prepared from the eggs of *Pandalus* or of *Scyllarus* lost weight, but were cured of xerophthalmia after 13 days. An extract prepared from the eggs of *Aristeus* also caused loss of weight, but the animals were cured of xerophthalmia after 6 days. Another extract prepared from the "conjonctif péristomacal" of *Aristeus* cured in 11 days and also caused a loss of bodyweight. Animals given injections of human serum alone gained weight, but xeropthalmia remained the same or became worse. The anti-xerophthalmia activity of the extracts, which was similar to that of oily solutions of the esters of astaxanthine given orally, could not be accounted for by the very small amounts of vitamin A, approximately 0·2 I.U., estimated to be present.—I. M. Sharman.

4331

MASSONET, R. Recherches sur l'activité vitaminique A des huiles de Pénéidés. [**Vitamin A activity of the oils of Penaeidae.**] *C.R. Soc. Biol.*, 1956, **150,** 170–173.

Three male rats, each of which received 3 I.U. vitamin A daily, were mated 100 days after weaning with 3 females which had been given 90 mg. daily of oil from the hepatopancreas of the crustacean *Aristeus antennatus*. The females aborted their young, and when killed at 5 months had no vitamin A in their liver. The males had only traces of vitamin A in their liver. In a second experiment the vitamin A was given to the females and the oil to the males. They produced no young and when killed the males had no vitamin A in their liver, and the females had 20 μg. vitamin A per g. liver. In a third experiment with groups each of 3 males and 3 females, all were given 1 mg. α-tocopherol daily. In one group both sexes received 90 mg. daily of the hepatopancreatic oil; they produced no young and had no vitamin A in liver. In another the males received 15 μg. vitamin A daily and the females oil from the "conjonctif péristomacal" (see above abst.) equal in activity to the oil from hepatopancreas. Their young were aborted and the females had no vitamin A in the liver; the males had 250 μg. per g. In a third group the oil was given to the males and vitamin A to the females. They produced no young and at death the males had no vitamin A in the liver and the females had 250 μg. per g. Animals in a fourth group received 5 I.U. vitamin A daily and those in a fifth group 15 I.U. daily, Females of both groups gave birth to normal litters. The livers of the animals of group 4 had an average of 20 μg. vitamin A per g. and of group 5 an average of 210 μg. per g.

HARMS, R. H., CAMP, A. A., REID, B. L., GRANT, E. L., CREECH, B. G. and COUCH, J. R. **Evidence for a substance in fish solubles which enhances vitamin A storage in chick livers.** *Poultry Sci.*, 1956, **35,** 285–291. [Dept. Poultry Husb., Texas Agric. and Mech. Coll. System, College Station.]

Chicks from hens receiving an adequate diet were given a basal ration of ground milo, soya bean meal, minerals and vitamins. Vitamin A, 2000 or 4000 I.U. per lb. feed, was supplied as fish oil concentrate or stabilised vitamin A. The diet was given alone or supplemented with 3 per cent. condensed fish solubles, or a water extract of them, or the residue remaining after the water extraction. The addition of fish solubles to the diet which contained 2000 I.U. vitamin A from either source increased storage of the vitamin in the liver four-fold in chicks 10 weeks old. Substantial increases in vitamin A were found also in the livers of chicks 3, 4 and 9 weeks old, when the diet contained 4000 I.U. vitamin A from either source. The substance in fish solubles which favoured storage of the vitamin was present in the water-soluble fraction. The residue contained an appreciable amount of vitamin A, estimated chemically, but its biological value was low compared with that of a corresponding amount of vitamin A from fish oil. It is therefore presumed that the vitamin A in fish solubles is not readily available or that its chemical estimation is inaccurate because of the presence of other substances.

E. M. Cruickshank.

4333

SQUIBB, R. L., BRAHAM, J. E. and SCRIMSHAW, N. S. **Absorption of vitamin A in aqueous and oil solutions by depleted New Hampshire chicks.** *Poultry Sci.*, 1956, **35,** 73–76. [Inst. Agropecuario Nac., Guatemala.]

Groups of from 8 to 15 chicks, depleted of vitamin A, were given vitamin A in aqueous or oily medium by mouth or by injection. The rate of absorption was gauged by estimating the vitamin A content of the serum without, and at intervals of up to 11 days after, administration of the vitamin. Absorption was poor in chicks injected subcutaneously with 1800 I.U. vitamin A in oil; the maximum response of 5 μg. vitamin A per 100 ml. serum occurred only after 4 days. When 7500 I.U. was given by subcutaneous or intramuscular injection in oil, the maximum responses were 33 and 29 μg., respectively, after 7 days. When 7500 I.U. in aqueous medium was given by intramuscular injection the maximum response of 66 μg. was attained after 24 hr. After oral administration of 7500 I.U. in aqueous or oily medium, the maximum of 50 to 51 μg. was found

within 24 hr. Death from vitamin deficiency was not prevented by parenteral injection of the vitamin in oil, probably owing to its slow absorption, but no death occurred when maximum absorption was attained within 24 hr.

HIGH, E. G. and WILSON, S. S. **Studies on vitamin A ester : alcohol partition between the liver, kidneys and plasma of rats.** *Arch. Biochem. Biophys.*, 1956, **62,** 163–172. [Dept. Biochem., Meharry Med. Coll., Nashville, Tenn.]

Albino rats maintained on a diet deficient in vitamin A were given 13 μg. vitamin A ester daily for the first 3 weeks ; they were killed at intervals up to 49 days after withdrawal of vitamin A. Vitamin A ester and alcohol, separated chromatographically, were estimated in the kidneys, liver and blood plasma. In the kidneys, the proportions of vitamin A ester and alcohol were about the same, but in the liver the ester form always predominated, constituting from 68 to 91 per cent. of the total vitamin A present. The proportion of ester in the blood plasma declined from 41·6 per cent. initially to 3·8 per cent. after 49 days. Other rats deprived of vitamin A were given daily, for up to 19 days, vitamin A ester in cottonseed oil in amounts ranging from 49 to 180,000 μg. In their kidneys there was relatively more of the ester form, from 52 to 77 per cent. of the total present. In the liver the ester form again predominated with values between 91 and 98 per cent. of the total. The total amount of the vitamin present in the liver varied widely ; the concentration in the plasma remained nearly constant. The results support the view that the concentration of vitamin A alcohol in the plasma is independent of the total concentration of the vitamin in the liver or kidneys.

LIU, C. H., FRAPE, D. L., ASHTON, G. C. and CATRON, D. V. **Vitamin A content of the livers of suckling pigs.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 571–572. [Iowa Agric. Exp. Stat., Ames.]

Fat and vitamin A were estimated in the liver of 35 piglets aged from 1 to 42 days. Average concentrations of vitamin A, in μg. per g. liver, were 15·1 at 1 day of age, 30·6 at 7 days, 26·4 at 14, 24·4 at 21, 21·7 at 28, 19·3 at 35 and 17·4 at 42. The mean total amount of vitamin A in the liver rose from 570 μg. at 1 day old to 2281 at 7 days, after which it continued to rise, though less rapidly than during the first week. At 14 days of age the average total content was 2689 μg., at 21, 3184, at 28, 3889, and at 35, 4539.

4336

SIBBALD, I. R., BOWLAND, J. P. and BERG, R. T. **The relationship between the blood plasma vitamin A levels of sows and of their suckling pigs.** *J. Animal Sci.*, 1956, **15,** 400–406. [Dept. Animal Sci., Univ. Alberta, Edmonton.]

Yorkshire sows with one male and one female pig from each litter were taken at random, grouped according to the season in which they farrowed, and given a ration with 15 per cent. protein based on oats and barley in a 2 : 1 ratio. Vitamin A, which was included in the ration during lactation at the rate of 1,250,000 I.U. per ton, was estimated in blood at weekly intervals.

The mean values, in μg. per 100 ml., for sows farrowing in January were 35·2, 22·2 and 22·5 on the 7th, 28th and 49th days, respectively. The mean values for the young pigs on the same days were 22·1, 15·6 and 16·8. For those that farrowed in February and March the corresponding values were, for the sows, 28·6, 37·2 and 39·8, and for the young pigs 24·9, 32·5 and 28·1 ; in July, 49·2, 33·9 and 41·0 for the sows, and 46·5, 28·2 and 27·4 for the young pigs ; and in September 49·8, 40·9 and 36·3 for the sows, and 35·9, 30·3 and 28·0 for the young pigs. Values for some groups are given at 14, 21, 35 and 42 days of age as well. From regression equations for the results the vitamin A content of the plasma of the sucking pigs could be predicted from that of the plasma of their dams. Predictions were most accurate when the sucking pigs were 28 days old, at which age the equation was $Y = 0{\cdot}473\,X + 10{\cdot}8$, where Y and X were the respective values for the young pigs and their dams.—R. J. Ward.

ÓCSAG, I. and SRÉTER, F. Időszaki változások lovaink szérumának karotinoid és A-vitamin koncentrációjában és ennek gazdasági jelentősége. [**Seasonal variations in the concentration of carotenoids and vitamin A in the serum of horses, and their economic significance.**] *Rep. Fac. Animal Husb., Hung. Univ. Agric. Sci.*, 1955, **1,** No. 2, 3–27. [Inst. Animal Breeding, Univ. Agric. Sci., Budapest.] Russian, French, English and German summaries.

Carotenoids and vitamin A were estimated in the serum of horses and foals at different seasons and under different conditions of feeding. The carotenoid content of the fodder was low except during late spring and summer, and the difference was reflected in the serum carotenoid values. Abortions were especially common in mares with serum carotenoid values below 15 μg. per cent., and fertility was highest on farms where the value was kept up to 15 or 20 μg. per cent. during the

winter. Where values were low in winter, fertility improved when green feed became available in spring. Wider use of good hay, carrots and silage is recommended, especially for foals. In the serum the values for vitamin A tended to vary inversely with those for carotenoids, but towards the end of winter both were often low. The values for carotenoids were higher and for vitamin A lower in foals than in mares. (From English summary.)—D. Duncan.

4338

Ócsag, I., Sréter, F. and Monostori, I. Az újszülött és a szopóscsikó karotinoid és A-vitamin ellátottsága különös tekintettel a kancák tejelési időszakára és takarmányozására. [**The supply of carotenoids and vitamin A to newborn and sucking foals in relation to the period of lactation and the diet of the mares.**] *Rep. Fac. Animal Husb., Hung. Univ. Agric. Sci.*, 1955, **1**, No. 8, 23–37. [Inst. Animal Breeding, Univ. Agric. Sci., Budapest.] Russian, German and English summaries.

Some of the mares studied previously (preceding Abst.) and their foals were investigated further, Carotenoids and vitamin A were estimated in the blood of the mares before and at intervals after foaling.

The carotenoid content of the blood was higher after foaling than a week before and it continued to rise for about 6 days. The vitamin A content did not always rise immediately, but was always higher by the sixth day after foaling.

In foals at birth the serum carotenoid value was always, and the vitamin A value almost always, below that of the mother. The carotenoid content rose steeply. Colostrum contained up to 20 times as much vitamin A as later milk, but by about the third day the content was like that of milk. The carotenoid content of the colostrum was little, if at all, higher than that of later milk. Green fodder increased the vitamin A content of the milk more than the carotenoid content. It is suggested that foals which do not get colostrum should be given eggs for the first few days of life. (From English summary.)—D. Duncan.

4339

Hennaux, L. and Antoine, A. L'importance de la vitamine A en élevage bovin. [**Importance of vitamin A in cattle rearing.**] *Bull. Inst. agronom. Gembloux*, 1956, **24**, 40–53.

Records were kept of the amounts of colostrum and milk taken by a calf during the first 6 weeks of life. The daily vitamin A intake during successive weeks was then calculated according to the average values found by the authors for the vitamin A content of colostrum and milk, and also according to their lowest recorded values. By the first method of calculation the calf received nearly 4 times its reputed requirement of vitamin A during the first week of life, after which intake only slightly exceeded requirement. By the second method the requirement was again exceeded during the first week, but afterwards was not satisfied. Intake was lowest in the fifth week, which appeared to be a time of danger, since the vitamin A content of the milk was falling and was not yet balanced by the hay eaten.—T. Moore.

4340

Plotnikov, K. I. Gipovitaminoz telyat i ego profilaktika. [**Vitamin deficiency in calves and its prevention.**] *Veterinariya*, 1956, **33**, No. 3, 70–72. [New Siberia nivos.]

Low values for vitamin A and carotene in the blood and colostrum of cows caused losses of calves. A meal from pine needles, given at the rate of 200 to 300 g. daily, improved the health of calves and sheep. Chopped pine needles mixed with hay in the proportion 1 : 3, salt 30 g. daily per animal and bran 1 kg., were soaked in vats for 3 days in warm water at the rate of 1 litre to 1·5 or 2 kg. cut pine needles, and given to cows at the rate of 2·5 or 3 kg. per head.—H. Scherbatoff.

Davis, C. L., Elliott, R. F. and Lassiter, C. A. **The effect of lecithin, choline, and methionine on the vitamin A and carotene plasma levels and liver stores of young dairy calves.** *J. Dairy Sci.*, 1956, **39**, 440–447. [Dairy Sect., Univ. Kentucky, Lexington.]

In an experiment repeated in 3 separate years, male Jersey calves were sorted at random into 9 groups, each of 2 animals. All had a basal ration low in carotene, group 1 without supplement, group 2 with 25,000 I.U. vitamin A daily, groups 3, 4 and 5 with the same amount of vitamin A and daily 3 g. DL-methionine or 2 g. choline chloride or 10 g. vegetable lecithin, groups 6 to 9 with 25,000 I.U. carotene daily alone or with one of the lipotropic substances. Blood samples were taken weekly, and liver and kidneys were taken at slaughter on the 42nd day for estimation of vitamin A and carotene.

In the experiment with vitamin A, the mean value for vitamin A in the plasma in groups 1 to 5 was 9·6, 17·6, 15·0, 16·1 and 20·1 μg. per 100 ml. The vitamin A content of the plasma of the animals receiving vitamin A and lecithin was significantly higher, at a 5 per cent. level, than that in the groups given the other lipotropic substances but not significantly higher than that in the group given vitamin A

alone. The average carotene contents of the plasma were 18·0, 19·2, 17·9, 18·0 and 27·0 μg. per 100 ml. The average vitamin A contents of the livers were 12·6, 102·2, 123·7, 132·9 and 113·2 μg. per g. There was no significant difference between any of the 4 groups given vitamin A. In the experiment with carotene the carotene content of the plasma in groups 1, 6, 7, 8 and 9 was 18·0, 83·5, 137·4, 124·0 and 90·8 μg. per 100 ml. There was superiority, significant at a 1 per cent. level, in the absorption of carotene given with methionine over carotene given alone or with lecithin, and superiority, significant at a 5 per cent. level, in the absorption of carotene given with choline over carotene given alone or with lecithin. The lipotropic agents had no effect on storage of carotene in the liver. The vitamin A content of the liver in groups 1, 6, 7, 8 and 9 was 12·6, 11·6, 19·2, 10·3 and 14·8 μg. per g.—R. J. Ward.

4342

BONDI, A., VOLCANI, R., NEUMARK, C. and DAVIDSON, J. **On vitamin A and carotene levels in blood of Israel cattle.** *Refuah Vet.*, 1955, **12**, 17–27 in Hebrew; 127–122 in English. [Agric. Res. Stat., Rehovot.]

During the years 1951 and 1952 the quality of roughage was poor and much ill health was attributed to deficiency of vitamin A. The present survey dealt with blood and liver of cows and calves, and colostrum from herds where feeding had been improved and where it was still bad. Blood from healthy cows had values for carotene and vitamin A above the lower values accepted as normal but never up to the highest reported elsewhere. Where there was acute ill health, blood contained less than the normal amounts of carotene and vitamin A; samples of liver from such a herd had 0 and 28 I.U. vitamin A per g., and those from other herds were from 34 to 625. Calf liver had less, up to 72 I.U. per g.; 4 out of 8 samples had none and they were from a herd where cow liver gave from 205 to 475 I.U. per g. Colostrum on the first and second day had, per 100 ml., from 90 to 600 I.U. vitamin A and from 84 to 260 μg. carotene.

When more carotene was supplied to cattle suffering from deficiency, plasma carotene rose at once but vitamin A rose slowly. It is suggested that the deficient diet impaired the power to convert carotene to vitamin A and that recovery of the power to do so was slow.—I. M. Sharman.

4343

NARAYANAN, K. M., ANANTAKRISHNAN, C. P. and SEN, K. C. **Co-vitamin studies. 1. Variations in tocopherol, carotene and vitamin A contents in milk and butterfat of cows and buffaloes.** *Indian J. Dairy Sci.*, 1956, **9**, 44–51. [Southern Reg. Stat., Nat. Dairy Res. Inst., Bangalore.]

Specimens of milk fat from 40 Red Sindhi cows, 20 Gir cows, 50 crossbred cows and 8 Murrah buffaloes were examined twice a month from February 1954 to January 1955. The animals were given a mixture of, per cent., oats 25, gram 20, groundnut cake 20, wheat bran 20 and gram husk 15, and fodder consisting partly of green grass and partly of silage and *ragi* straw or *ragi* straw alone. For all the cows taken together the ranges and average values, per g. of fat, were for tocopherol 26·6 to 42·7 and 34·8 μg., for carotene 3·2 to 7·4 and 4·8 μg., and for vitamin A 19·4 to 33·9 and 25·9 I.U. There was no difference between the breeds for any of the three components. For the buffaloes corresponding values were for tocopherol 18·0 to 36·7 and 25·9 and for vitamin A 17·2 to 38·4 and 25·9. Differences between the values for cows and buffaloes were significant for tocopherol but not for vitamin A.

In terms of milk the amounts of tocopherol and vitamin A were for cows 837 μg. and 620 I.U. per lb. and for buffaloes 896 μg. and 906 I.U. per lb.

Significantly more tocopherol, carotene and vitamin A were found in milk fat and milk during the monsoon season from June to November than in the hot or the cold season.—I. M. Sharman.

4344

BORRELL, S. Método de compensar la deficiencia de vitamina A en la ración alimenticia. [**Means of compensating for deficiency of vitamin A in the normal diet.**] *An. Bromatol.*, 1956, **8**, 19–37. [Dept. Invest. Bromatol., C.S.I.C., Univ. Madrid.] English summary.

Carotene was estimated by a modification of Booth's method (Abst. 2149, Vol. 15). The ranges and mean values for carotene and vitamin A are tabulated for a number of green foods, vegetables and fresh and preserved fruits, and the vitamin A content of several kinds of fish is given also. Selection of the better sources of vitamin A would eliminate the need for therapeutic administration of the pure vitamin for incipient deficiency.

VITAMIN D

4345

LAUGHLAND, D. H. and PHILLIPS, W. E. J. **Quantitative estimation of vitamins D_2 and D_3 in pure solution.** *Anal. Chem.*, 1956, **28,** 817–819. [Div. Chem., Sci. Serv., Dept. Agric., Ottawa.]

The basis of the method is the formation of coloured complexes between the D vitamins and a mixture of furfural and sulphuric acid. The spectral absorption of the reaction product was greatly affected by concentration of acid, temperature and duration of reaction, so that conditions are strictly laid down. Within the temperature range from 10° to 20° C., maximum absorption for vitamin D_2 was at 565 mμ. and the extinction coefficient was 950; the corresponding values for vitamin D_3 were 490 mμ. and 1060. The smallest amount of vitamin D that could be estimated was 15 μg.—E. M. Hume.

4346

SCHUBERT, K. Über die partielle Hydrierung des Vitamins D_2. Ein Verfahren zur Herstellung von kristallisiertem Dihydrovitamin D_2II. [**Partial hydrogenation of vitamin D_2. A procedure for the preparation of crystalline dihydrovitamin D_2II.**] *Biochem. Ztschr.*, 1956, **327,** 507–514. [Inst. Mikrobiol., Jena.]

For previous work see Abst. 3437, Vol. 25.

For the maintenance of the side chain and to secure that only one of the 3 conjugated double bonds in vitamin D_2 was hydrogenated, Raney nickel was preferred to platinum or palladium, with methanol as solvent. The characteristic ultraviolet spectrum of the dihydrovitamin D_2II thus obtained was modified by raising the temperature or changing the *p*H in either direction.

Dihydrovitamin D_2II was produced during the preparation of dihydrotachysterol. Its structure is discussed.—E. M. Hume.

HAAVALDSEN, R. and NICOLAYSEN, R. **Studies in calcium metabolism in rats. 1. A long term study in rats given an optimal diet with and without vitamin D.**

HAAVALDSEN, R., EGNUND, K. M. and NICOLAYSEN, R. **2. The interaction of vitamin D and the endogenous factor.**

NICOLAYSEN, R. **3. The adaption to low Ca intakes of old rats.** *Acta physiol. scand.*, 1956, **36,** 102–107; 108–113; 114–118. [Johan Throne Holst's Nutrit. Res. Inst., Univ. Oslo.]

1. Young male rats weighing from 50 to 60 g., 150 in all, were given a diet of, per cent., acid-precipitated casein 10, dried egg albumin 3, dried brewer's yeast 3, arachis oil 5, wheat flour 76, vitamin B_{12} mixture (20 mg. in 1 kg. rice starch) 0·5, KH_2PO_4 0·8, and $CaCO_3$ to give 0·5 per cent. Ca in the diet. The percentage of P was 0·5. Some of the rats received 70 I.U. vitamin D weekly. [It is stated further that all rats received also 140 I.U. vitamin D weekly, but it seems more probable that this should be 140 I.U. vitamin A.] Rats were killed at intervals of 5 or 6 weeks up to the age of 81 weeks. Ca and ash were estimated in the bones, and Ca balance experiments were made for periods of from 3 to 6 weeks.

In the rats given vitamin D weight gain was somewhat superior, and absorption of Ca was definitely superior, for the first 15 weeks but not later; the deficit of Ca incurred by those without vitamin D was never subsequently made up. Both groups excreted very little Ca in the urine; those given vitamin D excreted somewhat the larger amount. The bones of those given vitamin D contained more ash.

2. In one experiment, rats were given a diet of, per cent., whole wheat 84, acid-precipitated casein 10, dried brewer's yeast 3, NaCl 1, KH_2PO_4 0·8 and vitamin B_{12} mixture, as in the preceding Abst., 0·5. In the other experiments, rats were given the same diet as in the preceding Abst., except for variations in the Ca content and the introduction of Na oxalate to increase the negative Ca balance in 2 experiments.

In the first experiment, 18 rats were maintained on the first diet for about 30 weeks from 6 weeks old. For the last 6 weeks 6 of them were given 70 I.U. vitamin D a week. Ca absorption was measured throughout. The mean amount absorbed increased up to about the 14th week of age and then, when weight increase was slackening, declined to less than half the initial value unless vitamin D was given, when there was a great increase followed by a moderate decline but not to as little as the initial value.

The same decrease in the absorption of Ca, followed by increase when vitamin D was given, was shown by rats having had the diet described in the preceding Abst., and containing, per cent., Ca 0·5 and P 0·5 for 35 or 69 weeks. Adult rats which had lost several hundred mg. Ca during about 20 weeks showed greatly increased absorption when 10 I.U. vitamin D were given daily.

Female rats more than 2 years old were given vitamin D for about 20 weeks. A strongly negative Ca balance was induced at intervals by giving Na oxalate. Each such period was followed by an absorption of Ca much greater than in the period before oxalate was given, although vitamin D was then being given.

It is concluded that " The absorption of calcium is throughout life subject to a regulation by vitamin D and an endogenous factor of unknown nature. Vitamin D appears to be the primary regulating factor without which the endogenous factor cannot develop its action. "

3. In 3 experiments, 33 rats in all were given the same diet as in Part 1. They had been used for many months previously for balance experiments in which vitamin D was given, and were in positive Ca balance on a diet containing 0·25 per cent. Ca. In the first experiment rats aged from 21 to 28 months, and in the second experiment rats aged from 26 to 32 months, having a diet with 0·04 per cent. Ca and given vitamin D, were almost always in positive balance with an intake of 6 mg. daily.

In the third experiment rats aged 28 months were in positive balance on a diet with 0·25 per cent. Ca and an intake of about 40 mg. After a month the percentage of Ca was reduced to 0·04 with an intake of 6 or 7 mg., and all the rats were in negative balance. Change after another month to a diet with 0·098 per cent. Ca and an intake of from 13 to 15 mg. reduced the negative balance but rendered it positive only in one rat. The surviving rats were by this time more than 30 months old. The amount of Ca in the urine was increased, which, it was considered, might be evidence of a very slight increase in bone catabolism in such old rats.—E. M. Hume.

4348

JOSHI, J. G. and DIKSHIT, P. K. **Effect of vitamin D on the phosphorus content of rachitic rat cartilage.** *Nature*, 1956, **177**, 625. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor, S. India.]

Rats 4 weeks old, in 6 groups of 10 and 1 of 20, were given a rachitogenic diet. After 21 days one group was killed and the epiphyseal cartilage from the tibia was removed and dried at 90° C. At the same time all the rest were given a single dose of 4000 I.U. vitamin D and groups of rats were killed at intervals of 24 hr. afterwards, up to 144 hr., and the tibial cartilages were removed in the same way. The cartilages were wet-ashed and P was estimated in them colorimetrically. The mean value, in μg. P per mg. dry cartilage, was 9·78 before vitamin D was given, and 11·00 after 24 hr., increasing to 20·94 after 96 hr. The value then began to decline again, and was 17·21 after 120 hr. and 12·21 after 144 hr. The reason for the decline after 96 hr. was not clear, but it is pointed out that that is the time when maximum increase in calcifying capacity after administration of vitamin D is shown by cartilage *in vitro*, and when calcification begins *in vivo*.

HANSSLER, H. Über den Einfluss der Nebennierenrinde auf das Knochenwachstum Vitamin-D-frei ernährter Ratten. [**Influence of the adrenal cortex on the growth of bone in rats deprived of vitamin D.**] *Klin. Wochenschr.*, 1956, **34**, 646–647. [Kinderklin., Univ. Tübingen.]

Young rats 4 weeks old, 208 in all, were maintained on the low-P rachitogenic diet, Steenbock No. 2965. For from 10 to 14 days groups of from 18 to 33 were given daily 0·5 or 1·25 or 2·5 mg. cortisone or 1 I.U. vitamin D_3 or both cortisone and vitamin D_3. Two groups of 18 rats had the adrenal glands removed and during 7 or 8 days were given 2000 or 1 I.U. vitamin D_3. At the end of the experiment an X-ray picture was taken, Ca and P in the blood serum were estimated and histological examinations were made.

In intact rats cortisone lowered serum inorganic P but did not affect Ca. It reduced the weight of the thymus gland and spleen, and promoted their involution, and it induced skeletal changes resembling the beginning of healing in rickets. Given with vitamin D_3 it reinforced the vitamin's effect. In adrenalectomised rats the antirachitic effect of 1 I.U. vitamin D_3 was less than in intact rats.

With a rachitogenic diet low in Ca, cortisone had a well marked antirachitic effect.

KANDUTSCH, A. A., MURPHY, E. D. and DREISBACH, M. E. **Provitamin D in certain sebaceous tissues of the mouse and guinea pig.** *Arch. Biochem. Biophys.*, 1956, **61**, 450–455. [Roscoe B. Jackson Mem. Lab., Bar Harbor, Maine.]

Preputial glands from 220 Swiss mice 22 months old, anal glands from 10 male guineapigs weighing from 490 to 795 g., and material of a transplantable preputial gland tumour 7 weeks after being implanted into mice, were extracted with acetone and saponified with alcoholic KOH after evaporation of the acetone. The sterols were obtained by precipitation with digitonin. They were purified in different ways and recrystallised repeatedly. The spectral absorption between 230 and 320 mμ. and that of the product of reaction with the Liebermann Burchard reagent were measured, and compared with values for standard specimens of sterols. 7-Dehydrocholesterol constituted from 35·3 to 66·3 per cent. of the sterol mixture. Cholesterol and a substance reacting rapidly with the Liebermann Burchard reagent, tentatively identified as Δ^7-cholesterol, were present also. The concentrations of 7-dehydrocholesterol in the different tissues were several times greater than any reported for other organs or tissues.—E. M. Hume.

4351

RAINES, T. V. and WINKEL, F. H. **Avian rickets in Wisconsin.** *J. Amer. Vet. Med. Assoc.*, 1956, **128,** 414–415. [Poultry Dis. Diagnostic Sect., Animal Dis. Diagnostic Lab., Wisconsin Dept. Agric., Madison.]

Rickets was reported in 5-week-old chickens from 3 flocks. The clinical signs and post-mortem findings justifying the diagnosis are described. In 2 of the flocks coccidiosis also was diagnosed. The flocks were all having the same commercial feed, which apparently did not provide the preventive doses of vitamin D_3 and drugs declared to be present. In trials with rats the suspected feed was found to have no vitamin D.—T. D. Bell.

4352

CHITRE, R. G. and DAMLE, V. M. **Effect of high doses of vitamin-D on nitrogen excretion in albino rats.** *J. Postgrad. Med., Bombay*, 1956, **2,** 106–116. [Sect. Biochem., Dept. Physiol., Seth G.S. Med. Coll., Bombay 12.]

Total N, urea, ammonia, uric acid, creatinine N, Ca and P were estimated in the 24 hr. urine of 4 male rats, from 110 to 120 days old, maintained on a stock diet. The intakes of N, Ca and P were measured. The study lasted for 5 preliminary periods of 3 days each, then for 10 periods during which 2 of the rats were injected with 10,000 I.U. vitamin D_2 daily, and then with 20,000 I.U. daily; they died after from 63 to 75 days in all. In the rats given vitamin D the output of all forms of N, but especially urea, increased when 20,000 I.U. daily was given and N balance became negative. Signs of toxicity then became severe, with loss of weight, increased output of Ca and P, and reduced food intake. It was concluded that there was no damage to the liver in vitamin D excess and that it was exogenous protein metabolism that was primarily affected.

To test the conclusion the experiment was repeated with 4 rats given a protein-free diet. In those given vitamin D death occurred sooner than in the first experiment but no increase in the urinary excretion of N in any form took place.

HERZFELD, E., LOUDON, M. and ZWEYMÜLLER, E. Beitrag zur experimentellen Vitamin D-Vergiftung beim Hund. 2. Das Verhalten der maximalen tubulären Rückresorption von Phosphat (Tm_{PO_4}) bei infolge subakuten Vitamin D-Vergiftung verringerter Glomerulusfiltrationsgrösse. [**Experimental vitamin D intoxication in the dog. 2. The effect on maximum tubular re-absorption of phosphate (Tm_{PO_4}) of diminished glomerular filtration due to sub-acute vitamin D intoxication.**] *Ztschr. ges. exp. Med.*, 1956, **127,** 272–280. [Inst. Pharmakol., Univ. Vienna.]

For part 1 see Abst. 335, Vol. 26.

2. With the method described in part 1, 84 clearance tests were made on 11 female dogs, weighing between 10 and 24 kg., before and after administration of from 1 to 4 mg. vitamin D_2 per kg. bodyweight. The tests after administration of vitamin D were started when the weight had begun to fall and residual N in the blood had begun to rise. Serum inorganic P was estimated. Degrees of vitamin D intoxication were produced, classified as transitory, moderate and fatal. The degree of intoxication suffered by the different dogs in response to the same amount of vitamin D varied widely. With the onset of signs of intoxication the rate of glomerular filtration was slowed and so to a smaller extent was the rate of plasma flow through the kidneys. As the intoxication became more severe, those defects increased, and maximum tubular re-absorption of phosphate began to fail, but the failure was not related in degree to the extent of the failure of glomerular filtration and was not secondary to it.

BÄHRECKE, G. Über die Haltbarkeit von Vitamin D-Zusätzen in Futterkalk bzw. dessen Komponenten. [**Stability of vitamin D additions to feeding chalk or its components.**] *Arch. Tierernährung*, 1956, **6,** 110–128. [Anst. Vitaminforsch., Potsdam-Rehbrücke.]

The materials were tested prophylactically on groups of 10 rats given McCollum's rachitogenic diet 3143 modified. Four groups received every other day graded doses of a preparation of vitamin D_2 as standard, one group received no addition, and the remaining groups had appropriate amounts of the test substance. Solid preparations were given as pills. After 15 days an X-ray picture was taken of the left knee joint; 5 degrees of rickets were recognised. In all, 4000 rats were used. Certain commercial preparations were tested, and laboratory mixtures were made of vitamin D_2 and sometimes of vitamin D_3 with Ca phosphates or Ca carbonate, alone or with different proportions of other salts or salt mixtures. The materials were tested as soon as prepared and at intervals up to 12 months afterwards. They were stored in the dark. When the amount of P in the material was sufficient to have an antirachitic effect, the effect remained constant and did not affect measurement of the loss of vitamin D activity during storage.

The stability of vitamin D in the different mixtures varied greatly. The best result was obtained when the vitamin was added in alcoholic solution to $CaCO_3$, but if it was in oil solution the

stability was poor. Stability with phosphates of Ca was not good, and many other salts were destructive.—E. M. Hume.

TEŠIĆ, D. Rendgenološka slika eksperimentalnog rahitisa prasadi. [**The X-ray picture of experimental rickets in baby pigs.**] *Acta vet., Belgrade*, 1955, 5, No. 4, 59–74. [Inst. Rendgenol. Fiz. Terap., Vet. Fak., Univ. Belgrade.] German summary.

The article is the author's abstract of his thesis. Thirty young pigs of different ages were given a rachitogenic diet and 10 others had a normal diet. X-ray photographs were made of the distal ends of the radius and ulna, usually every 5 to 8 days, to study the development of rickets especially in its early stages. A pre-rachitic stage, characterised by loss of density in the diaphysis and metaphyseal spongiosa, a pre-clinical stage in which the disorder could readily be recognised radiographically, and early and late clinical rickets are described and illustrated with 21 X-ray photographs. The findings of other workers, who have claimed that diagnosis is possible only when the clinical stage is reached, are criticised.—D. Duncan.

NAIR, P. P. and MAGAR, N. G. **Determination of vitamin E in blood.** *J. Biol. Chem.*, 1956, **220,** 157–159. [Dept. Biochem., Inst. Sci., Bombay.]

Blood, oxalated or clotted, was centrifuged for 20 min. at 2000 r.p.m. and from 1 to 2 ml. of plasma or serum was shaken with 0·5 ml. of 5 per cent. NaOH. The mixture was allowed to stand for 6 hr. after which it was diluted with 10 ml. distilled water and extracted twice with 5 ml. light petroleum. The washed extract was evaporated to dryness and the dry residue was dissolved in 1 ml. of a 0·394 per cent. solution of phosphomolybdic acid in glacial acetic acid. Exactly 5 min. after addition of the phosphomolybdic acid, the solution was diluted with 3 ml. purified ethanol and the colour density was read on a spectrophotometer at 725 mμ. A curve of reference was constructed with pure α-tocopherol. In 25 samples of human blood serum the vitamin E content ranged from 0·36 to 0·41 mg. per 100 ml. When tocopherol was added to rat blood serum recovery averaged 98 per cent. It is claimed that interference from reducing substances other than tocopherol can be ignored, and that the procedure is free from interference by vitamin A, calciferol, cholesterol and carotenoids.—R. J. Ward.

DELMAS, L. Dosage de l'α-tocophérol du sang humain par chromatographie sur papier. [**Estimation of α-tocopherol in human blood by paper chromatography.**] *C.R. Acad. Sci.*, 1956, **242,** 2595–2598.

Serum in amounts from 0·05 to 0·1 ml. was saponified in the presence of pyrogallol and nitrogen. The unsaponifiable residue was extracted with light petroleum, washed until free from alkali, dried with acetone and dissolved in a known amount of light petroleum or acetone. Paper chromatograms were prepared by immersing strips of paper in a 2·6 per cent. solution of spermaceti in petroleum to which had been added 4 per cent. of ferric undecylate. The aqueous phase was 25 per cent. aqueous acetone, which ran about 8 cm. in 1 hr. at 22° C. After development, the spots of α-tocopherol were detected by spraying with a solution of potassium ferricyanide and were compared with standard spots of α-tocopherol. The most accurate estimations were made on from 0·4 to 0·9 μg. α-tocopherol, but 0·05 μg. was detectable. A difference of 0·02 μg. between 2 spots

was easily detected provided there was no difference in the shape of the spot. Separation of α-tocopherol, $R_F = 0{\cdot}45$, was possible from vitamin A alcohol, $R_F = 1{\cdot}0$, carotenoids, $R_F = 0{\cdot}1$, 0·36 and 0·70 and γ-tocopherol, $R_F = 0{\cdot}50$. A recovery of 94 per cent. was obtained when α-tocopherol was added to serum. Several samples of human serum were investigated by the method and the values ranged from 0·55 to 1·16 mg. per 100 ml.—R. J. Ward.

SCARDI, V. and BOERI, E. Alcune proprietà dell' α-tocoferilfosfato e dell'α-tocoferolo. [**Some properties of α-tocopheryl phosphate and of α-tocopherol.**] *Acta vitaminol.*, 1956, **10,** 57–63. [Ist. Fisiol. Umana, Univ. Naples.] French, English, German and Spanish summaries.

The reduction of ferric to ferrous cytochrome *c* and the behaviour of α-tocopheryl phosphate were followed spectrophotometrically with a Beckman apparatus. α-Tocopheryl phosphate showed some dissociation in alkaline medium. It was confirmed that reduction of ferric to ferrous cytochrome *c* by ascorbic acid was completely inhibited by α-tocopheryl phosphate even at low concentrations (see Jacobi *et al.*, Abst. 3365, Vol. 20). The inhibition was not affected by *p*H, so it did not depend on dissociation of α-tocopheryl phosphate. Reduction of ferric cytochrome *c* by cytochrome b_2 and lactate was inhibited by α-tocopheryl phosphate, but α-tocopherol had no power to activate or inhibit the reaction.—E. M. Hume.

BERG, B. N. **Muscular dystrophy in aging rats.** *J. Gerontol.*, 1956, **11,** 134–139. [Dept. Pathol., Coll. Phys. Surg., Columbia Univ., New York.]

Carcases of 417 male and 151 female rats of Sprague Dawley strain, ranging in age from 500 to 1186 days, were examined; some muscles were studied and the brain and spinal cord of individuals with severe muscular degeneration were examined. The rats had been weaned at 4 weeks of age and had been given Rockland "D free" pellets containing about 3·2 mg. α-tocopherol per 100 g. diet., the average daily intake of α-tocopherol by an adult rat being about 0·7 mg. Conditions of temperature, humidity and lighting were good.

Muscular dystrophy appeared after 2 years of age and its incidence increased with advancing age. The condition appeared earlier and with greater frequency in males. Histological changes in the muscles resembled those found in experimental deficiency of vitamin E.—G. F. Garton.

4364

WEINSTOCK, I. M., GOLDRICH, A. D. and MILHORAT, A. T. **Enzyme studies in muscular dystrophy. 2. Muscle dipeptidase activity and vitamin E-deficiency.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 302–305. [Dept. Psychiat., Cornell Univ. Med. Coll., New York.]

Rabbits maintained on a diet deficient in vitamin E were killed when signs of muscular dystrophy appeared, and portions of muscle from the legs, thighs and back were homogenised with 2 vol. of water or a 2 per cent. solution of KCl; extracts of muscle were prepared also. Other rabbits given vitamin E were similarly examined. With aqueous muscle extracts and glycyl-*l*-leucine as substrate, specific activity of dipeptidase rose from an average value of 155 for the non-deprived animals to 540 for the deprived. With glycylglycine as substrate the corresponding figures were 125 and 405, measured in the presence of Co^{++} ions as activator. With the muscle homogenates and glycyl-*l*-leucine, specific activity increased from 34 for the non-deprived animals to 310 for the deprived and with glycylglycine from 15 to 110, again in the presence of Co^{++} ions.

FINK, H. and SCHLIE, I. Verbesserung des Champignon-Eiweisses für das Wachstum junger Ratten durch Zusätze von Cystin, Methionin und Tocopherol. Ein Beitrag zur alimentären Lebernekrose der Ratte. [**Improvement of the protein of fungi for the growth of young rats by adding cystine, methionine and tocopherol. Dietary liver necrosis in the rat.**] *Naturwissenschaften*, 1956, **43,** 134–135. [Inst. Gärungswiss., Univ. Cologne.]

In a previous paper liver necrosis was described in rats fed on the fungus *Psalliota lispora* (Abst. 2073, Vol. 24). In the present experiment young albino rats were fed on a diet of the fungi alone or supplemented with cystine or methionine or vitamin E or cystine and methionine. Average weight curves were plotted for 90 or 120 days. Rats given the unsupplemented diet lost weight and failed to regain their initial weight. Those given cystine alone at first lost weight, then regained their initial weight in 15 days and continued to grow for the rest of the experiment. Those given methionine grew somewhat at first but later lost weight. In those given vitamin E weight did not change. Those given cystine and methionine grew well and at the end

of 120 days had gained about 71 g.; liver necrosis was least in this group. Methionine alone gave some protection against liver necrosis, as judged by survival time, but less than cystine alone. Vitamin E reduced necrosis in 60 per cent. of the animals. Possible modes of action of the substances are discussed.—I. M. Sharman.

FERGUSON, T. M., RIGDON, R. H. and COUCH, J. R. **Cataracts in vitamin E deficiency: an experimental study in the turkey embryo.** *Arch. Ophthalmol.*, 1956, **55,** 346–355. [Dept. Biochem., Agric. and Mech. Coll. Texas, College Station.]

Of 16 mature turkey hens given a diet without vitamin E but with supplements of other vitamins, 8 had in addition 20 mg. *d*-α-tocopheryl acetate per lb. diet for 9½ weeks and 40 mg. for 5½ weeks. The hens were artificially inseminated at weekly intervals for the 15 weeks and their eggs were collected daily and incubated. One or both eyes from 109 embryos, 55 from the non-deprived group and 54 from the deprived, varying in age from 5 to 28 days, were examined. Embryos in the deprived group showed a keratoconus-like change when 19 or more days old. There were lens opacities in one or both eyes of 21 embryos from the deprived group and in 2 embryos from the non-deprived group. The most conspicuous change in the lens was liquefaction of the protein which might start anywhere and, where liquefaction was advanced, degeneration and proliferation occurred in cells of the lens epithelium. There were corneal opacities in 6 deprived and 1 non-deprived embryo. It is suggested that the lens protein probably forms and then subsequently liquefies as the result of a chemical change. (See also Absts. 1889, 4833, Vol. 25.)—I .M. Sharman.

BLACKMORE, J. C. and WILLIAMS, P. C. **Tocopherol deficiency in rats and mice fed on pelleted diets.** *J. Animal Tech. Assoc.*, 1955–1956, **6,** 71–73. [Imp. Cancer Res. Fund, London, N.W.7.]

Mice fed on a cubed diet prepared according to formula No. 86 of the Rowett Research Institute bred at a subnormal rate during the winter of 1954–55. Of the 4 strains, C_{57}BL, A, Simpson and C_3H, only the last was seriously affected. In a 19 weeks' experiment mice of the C_3H strain in 2 groups were given 10 mg. α-tocopheryl acetate thrice weekly during weeks 9 to 15 or during weeks 1 to 4. The tocopherol supplement did not increase the number of litters born, but significantly increased the size of the litter. The percentage of young weaned in the first 4 weeks was 1 and 32, respectively, in weeks 5 to 8, 0 and 38, in weeks 9 to 16, 35 and 18; neither group weaned any in the ensuring 4 weeks. The increase in litter size was maintained after treatment ceased. It is recommended that vitamin E supplements should be given as a routine to breeding colonies of mice.

Rats were not adversely affected to the same extent as the mice during the winter of 1954–55 and continued to breed but at a subnormal rate.

CHRISTENSEN, F. and DAM, H. **Reproduction capacity of rats in relation to diet. 3. Influence of diets containing no added fat with and without vitamin E and certain artificial antioxidants.**

CHRISTENSEN, F., DAM, H. and GORTNER, R. A. **4. Influence of diets containing no fat, lard freed from tocopherol, and of vitamin E and methylene blue.**

CHRISTENSEN, F. and DAM, H. **5. Absence of influence of high casein and addition of vitamin B_{12} on vitamin E deficient diets.** *Acta physiol. scand.*, 1956, **36,** 82–86; 87–96; 97–101. [Dept. Biochem., Polytech. Inst., Copenhagen.]

3. Seven groups of 12 female rats were given a basal diet without vitamin E or added fat. Groups 1 and 2 had vitamins A and D in peanut oil and group 2 had 0·02 per cent. α-tocopheryl acetate in the food. Groups 3 to 7 inclusive received vitamins A and D in aqueous colloidal solution and group 4 had also 0·126 per cent. methylene blue, group 5 had 0·025 per cent. tetraethylthiuram disulphide, group 6 had 0·5 per cent. nordihydroguaiaretic acid and group 7 had 0·02 per cent. α-tocopheryl acetate. After 70 days on the diets the survivors were mated with normal males of the same age. By the tenth week 4 rats had died in group 4, 12 in group 6 and 1 in group 7. Methylene blue appeared to prevent the tails becoming scaly. Rats of groups 1, 3, 5 and 6 gave birth to no young. All rats of group 2 which had vitamins A and D in oil and vitamin E produced litters, all of which died within 6 days. Of the 8 survivors in group 4 receiving methylene blue, 2 had litters which did not survive, and 5 of the 11 rats of group 7 which received the aqueous emulsion of vitamins A and D and α-tocopheryl acetate had litters which did not survive beyond 6 days.

4. Female rats were divided into 15 groups of 8 rats and were given a basal diet without tocopherol and fat for 62 days, after which 3 groups were given the basal diet alone, or with 0·02 per cent. α-tocopheryl acetate, or with 0·126 per cent. methylene blue; 3 groups had the same diet in which 20 per cent. sugar was replaced by 20

per cent. lard, alone, or with tocopherol, or with methylene blue ; 3 groups had diets like the last 3 but with lard in which the tocopherol content had been reduced by adsorption chromatography from 7·8 μg. per g. to 0·6 ; 3 groups had the basal diet with 2 per cent. lard, alone, or with tocopherol or methylene blue and 3 groups had diets like the last, but with 2 per cent. purified lard. After 21 days on the second diet they were mated with normal males. Lard in the diet prevented kyphosis and, except in the groups receiving 2 per cent. of the purified lard, prevented abnormal accumulation of cerumen. Teeth were not depigmented in groups on the fat-free diet or the diet containing 2 per cent. lard. In groups receiving the diet with 20 per cent. lard, tocopherol and methylene blue prevented depigmentation, but it was not prevented by methylene blue in groups receiving purified lard. No litter was born to rats given the basal diet with or without fat. Methylene blue was effective only in the group receiving the diet with 20 per cent. untreated lard, where 6 of the animals produced litters. Vitamin E was effective in all animals receiving lard, treated or untreated, but only 2 out of 5 rats had litters in the group receiving the fat-free diet and vitamin E.

5. Young female rats were divided into 6 groups of 10 and were given a diet without vitamin E and containing 4 per cent. lard. Groups numbered 8, 9, 11 and 12 had 20 per cent. casein in the diet and groups 10 and 13, 40 per cent. of casein with a corresponding reduction of sucrose. In addition groups 8, 9 and 10 received 0·02 per cent. α-tocopheryl acetate and groups 9 and 12, 1·5 μg. vitamin B_{12} in the diet. The rats were mated twice, the first time after 84 days and the second after 139 days on the diet. Neither vitamin B_{12} nor extra casein improved reproductive capacity and no litter was born to any group on the deficient diet, but the differences in the diet did not affect the normal reproduction of rats receiving added vitamin E.—R. J. Ward.

JENSEN, L. S., CARVER, J. S. and MCGINNIS, J. **Effects of vitamin E, N, N¹-diphenyl-paraphenylene diamine, and fish liver oil on reproduction in turkeys.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 386–388. [Dept. Poultry Sci., State Coll., Washington, Pullman.]

There were 12 pens with 11 turkey hens in each. Pairs of hens were given a ration deficient in vitamin E with no supplement, or 20 mg. α-tocopheryl acetate per lb. diet, or 2 per cent. pollack liver oil, or 2 per cent. pollack liver oil and 20 mg. α-tocopheryl acetate per lb. diet, or 2 per cent. pollack liver oil and 0·025 per cent. N, N′-diphenyl-*p*-phenylenediamine, or pollack liver oil, α-tocopheryl acetate and N, N′-diphenyl-*p*-phenylenediamine in the same amounts. During the last 12 weeks of the 21-week experiment one male was placed in each pen and the males were moved round each week. Eggs were incubated every 2 weeks and were candled on the 7th and the 24th day. During the latter part of the experiment tocopherol was estimated in a sample of 6 eggs from each pen.

The average percentage fertility of the six groups in the order given above was 66·5, 81·8, 58·6, 77·9, 73·2 and 69·2, and the average percentage mortality of the embryo after from 25 to 28 days was 13·4, 7·9, 41·2, 8·2, 13·5 and 7·2. The average percentage of fertile eggs per hatch was 66·0, 77·1, 38·6, 76·5, 74·0 and 79·5, and the average total tocopherol content of the egg yolks was 31·8, 72·7, 17·4, 23·0, 18·0 and 24·3 μg. per g.

BUNNELL, R. H., MATTERSON, L. D., SINGSEN, E. P. and EATON, H. D. **Studies on encephalomalacia in the chick. 5. The effect of fish oil and diphenyl-p-phenylenediamine on the vitamin E metabolism of the chick.** *Poultry Sci.*, 1956, **35,** 436–451. [Dept. Poultry Sci., Storrs Agric. Exp. Stat., Conn.]

For previous parts see Absts. 4361, Vol. 24 ; 4830, Vol. 25 ; 1687, Vol. 26.

5. A factorially designed experiment to test the effect of fish oil and the anti-oxidant diphenyl-*p*-phenylenediamine on vitamin E metabolism was made with chicks from hens fed on a normal diet or a diet low in vitamin E. The tocopherol content of the blood and liver was estimated at the start of the experiment, and subsequently at intervals up to 25 days. The initial stores of tocopherol in the livers of the non-deprived chicks were up to ten times as great as those of deprived chicks, but after 10 days on a vitamin-E-deficient diet the stores were about the same. The high initial value for the non-deprived chicks obscured the effect of the different treatments during the early part of the experiment, so the results obtained at first and up to 5 days of age were omitted from the statistical analysis. When the diet was supplemented, per lb., with 8 I.U. vitamin E, the tocopherol content of the plasma and liver increased in both deprived and non-deprived chicks, but there was no significant effect on bodyweight

or on the lipid content of the liver. Inclusion in the diet of 2 per cent. fish oil decreased the tocopherol content of the plasma and liver, depressed growth, particularly in the deprived chicks, and decreased the lipid content of the liver. Inclusion of the anti-oxidant slightly increased the tocopherol content of the liver in deprived but not in non-deprived chicks. It stimulated growth, particularly in the deprived chicks, increased liver lipid and partly counteracted the depression of growth produced by fish oil.

The possible mechanism by which the anti-oxidant exerted a protective action against encephalomalacia is discussed.—E. M. Cruickshank.

De Cicco, A. Manifestazioni di avitaminosi E nel pollo prodotte da somministrazione di o-cresolo. [**Signs of deficiency of vitamin E in the hen produced by administration of o-cresol.**] *Quad. Nutrizione*, 1954, **14**, 143–152. [Ist. Fisiol. Gen., Univ. Rome.] Summaries, French p. 191, English p. 193, German p. 195.

Three groups of 5 White Leghorn hens 10 months old and weighing from 1500 to 1700 g. were fed on a standard Italian ration including 70 g. daily of a laying mixture which contained, per kg., vitamin A 7000 I.U., vitamin D_3 1000 I.U., vitamin E 2 mg., vitamin B_1 5 mg., riboflavin 5 mg., nicotinamide 40 mg., pyridoxine 4 mg., pantothenic acid 12 mg. and vitamin B_{12} 8 μg. One group received no treatment, and 2 groups had weekly intramuscular injections of 500 mg. *o*-cresol succinate in olive oil, with and without 100 mg. α-tocopherol weekly. Treatment continued for 12 weeks. There was a cockerel with each group and all the eggs were incubated and the chickens were reared.

The general health of all the hens was good and their weight was constant. The number of eggs laid weekly was less from the second week of treatment in the group given *o*-cresol alone ; the effect was prevented by α-tocopherol. The eggs did not differ in fertility ; the percentage hatched, mortality and growth of the chick were similar for all 3 groups.

Serum tocopherol after 53 days, in μg. per 100 ml., was 270 in untreated birds, 30 in birds given *o*-cresol alone and 287 in birds given *o*-cresol and tocopherol. The estimation was made on 10 ml. plasma, and an earlier test with 5 ml. failed to reveal any tocopherol at all in samples from the second group.

After 10 weeks 2 untreated birds and 2 given *o*-cresol alone were killed. No pathological change was found, but the ovaries of the treated birds were smaller and had fewer maturing eggs. The 3 remaining birds of the treated group were given 1 g. α-tocopherol in 2 injections 5 days apart. Their serum tocopherol value was normal in 10 days, but egg production was normal only after 4 weeks.—D. Duncan.

4373

Salvi, F. and Mentasti, P. Azione protettiva della vitamina E sulle lesioni da Marcumar. [**Protective effect of vitamin E on lesions produced by Marcumar.**] *Acta vitaminol.*, 1956, **10**, 17–26. [Scuola Ostet., Vercelli.] French, English, German and Spanish summaries.

Three groups of 6 rabbits were given daily, per kg. bodyweight, 5 mg. Marcumar, an anticoagulant derivative of dicoumarol, alone or with 20 mg. α-tocopherol, or 20 mg. tocopherol alone for 24 days and then with Marcumar. The rabbits survived on the average for 9, 14 and 18 days. α-Tocopherol had little effect on prothrombin activity. The hyaluronidase-like effect of the anticoagulant on the intracellular and intrafibrillar substance of the mesenchyme was apparently strongly inhibited by α-tocopherol, and in the third group when α-tocopherol was given alone there was also less intradermal diffusion. α-Tocopherol inhibited the degenerate changes in the liver caused by Marcumar. The antihyaluronidase effect of α-tocopherol appeared to account for its protective effect against the anticoagulant.—A. M. Copping.

VITAMIN K

4375

Schulz, A. R. and Goss, H. ***In vivo* inhibition of phosphorylation by menadione.** *Biochim. biophys. Acta*, 1956, **20**, 443–444. [Dept. Animal Husb., Univ. California, Davis.]

The effect of menadione, 2-methyl-1 : 4-naphthohydroquinone, given by intraperitoneal injection to rats was to reduce the incorporation of radio-active orthophosphate into labile nucleotide phosphate in liver and heart tissue. Storage of

glycogen in the liver was reduced at the same time. The results suggested that the toxic effects of menadione might be due at least in part to the loss of phosphorylating capacity induced by it in the organism.—A. M. Copping.

4376

MARTIUS, C. Über die intracelluläre Verteilung des Vitamin K in verschiedenen Organen des Huhnes. [**Intracellular distribution of vitamin K in different organs of the fowl.**] *Biochem. Ztschr.*, 1956, **327**, 407–409. [Physiol. Chem. Inst., Univ. Würzburg.]

The distribution of vitamin K was investigated in nuclear, mitochondria, microsome and cytoplasm fractions of heart, liver and kidney tissue from chickens deprived of vitamin K for about 2 weeks and then given radio-active synthetic vitamin K_3 for several weeks. Measurement of radio-activity in extracts of cell fractions showed that almost all the vitamin K present was in the nucleus and mitochondria with negligible amounts in the other fractions. The vitamin K content of the cells was related to the nitrogen content; it was highest in heart tissue. Solvent distribution of the vitamin K of heart mitochondria between 95 per cent. methanol and *n*-heptane gave a distribution coefficient similar to that obtained with synthetic vitamin K_1, which was considered to be evidence that vitamin K_3 can be converted into vitamin K_1 in the animal body.—A. M. Copping.

4377

PHILLIPS, A. F. and CATER, D. B. **Protection by cysteine against the acute toxicity of a chemical radio-sensitizer ("Synkavit").** *Brit. J. Pharmacol.*, 1956, **11**, 128–131. [Dept. Radiotherap., Univ. Cambridge.]

Intravenous injection into adult rats of 1 m*M* per kg. bodyweight of tetrasodium 2-methyl-1 : 4-naphthohydroquinone diphosphate, Synkavit, caused death within 45 min. Cysteine and glutathione injected before or at the same time as the Synkavit protected. Synkavit caused convulsions without hypoglycaemia. A fall of oxidation-reduction potential in the brain after Synkavit suggested that its action was on the central nervous system.

GIACALONE, O. and BARDINO, M. Comportamento del glicogeno epatico in seguito a somministrazione di vitamina B_{12} o di vitamina B_1, nei ratti alimentati con dieta iperglicidica-ipoproticica. [**Behaviour of liver glycogen after administration of vitamin B_{12} or vitamin B_1 in rats fed on a high-carbohydrate, low-protein diet.**] *Quad. Nutrizione*, 1954, **14**, 153–158. [Ist. Fisiol. Umana, Univ. Palermo.] Summaries, French p. 191, English p. 193, German, p. 195.

For previous work see Giacalone, *Quad. Nutrizione*, 1953, **13**, 424.

Thirty male rats 8 to 9 weeks old and reared on milk, meat, bread and greenstuff to appetite were divided into 5 groups of 6. One group continued to receive the same diet, the others had a diet containing, per cent., sucrose 84, casein 10, salts 4, and cellulose 2; 1 group had in addition 5 mg. vitamin B_1 per head by mouth on alternate days, another had 8 μg. vitamin B_{12} on alternate days and the last had both vitamins. The experiment

lasted 21 days, and the rats were then fasted for 16 hr. and decapitated, and glycogen was estimated in the livers.

Liver glycogen, in g. per 100 g. fresh tissue, in the group on stock diet, the group given the high-carbohydrate, low-protein diet alone, and the 3 groups given vitamins as above, was 0·283 ± 0·01, 0·277 ± 0·009, 0·248 ± 0·012, 0·280 ± 0·022 and 0·243 ± 0·013, respectively. The values in the groups having vitamin B_1, with or without vitamin B_{12}, were probably not significantly different. Liver fat in the experimental groups, expressed as a percentage of that in the group having stock diet, was 134·8, 220·7, 268·1 and 284·9. Thus the presence of much fat did not affect the amount of glycogen in the liver.—D. Duncan.

4381

FREI, J. and RYSER, H. Relations entre oxydation phosphorylante et structure des mitochondries hépatiques de rats carencés en vitamines B_1 et B_2. [**Relations between oxidative phosphorylation and structure of liver mitochondria in rats deprived of vitamin B_1 and riboflavin.**] *Experientia*, 1956, **12,** 105–107. [Med. Clin., Univ. Lausanne.] English summary.

In rats deprived of vitamin B_1 a decrease in phosphorylation by liver homogenates was accompanied by a decrease in optical density of suspensions of liver mitochondria, caused by swelling of the mitochondria, but there was no significant change in the amount of protein nitrogen in the mitochondria.

In riboflavin deficiency there was no decrease in phosphorylation or optical density of mitochondria suspensions, but there was a significant fall in the amount of protein N in the mitochondria.

EAGLE, H. **Relative growth-promoting activity in tissue culture of co-factors and the parent vitamins.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 358–361. [Sect. Exp. Therap., Lab. Infect. Dis., Nat. Inst. Allergy Infect. Dis., Nat. Insts. Health, Bethesda, Md.]

For previous work see Abst. 1625, Vol. 26.

In media without vitamin B_1, pyridoxine, nicotinic acid, riboflavin, pantothenic acid or folic acid, the growth responses of mouse fibroblasts (strain L) to addition of the vitamins or of derived cofactors were studied. Cocarboxylase, flavin adenine mononucleotide and diphosphopyridine had, respectively, the same activity as vitamin B_1, riboflavin and nicotinamide. Pyridoxal phosphate, flavin adenine dinucleotide, triphosphopyridine and coenzyme A were, respectively, less active than pyridoxine, riboflavin, nicotinamide and pantothenic acid. Citrovorum factor was more active than folic acid, but *p*-aminobenzoic acid could not replace folic acid. The experiments did not explain the differences in activity, which might have been caused by variations in cell permeability or by partial blocks to utilisation.

4384

BOROS, E., PÁLYI, A., KÓS, T. and PAJZS, ZS. Nahrungswahl von Ratten in Verbindung mit der Ausbildung bedingter Reflexe. [**Choice of food by rats in connection with the establishment of conditioned reflexes.**] *Acta physiol. hung.*, 1955, **7,** 251–264. [2. Klin. Inn. Med., Med. Univ., Budapest.] Russian summary.

Male white rats weighing from 150 to 180 g., housed individually in wire-floored cages, after fasting for 20½ hr. were placed on a board and were expected to climb up a 2-m. rope to another board, on which were set the food containers, differing in size and shape but throughout the experiment always the same for the same food and in the same position. Ten rats were used in each experiment, and 10 other rats were used which were offered the same choice of foods for 3½ hr. daily in their cages. The average amounts eaten were ascertained daily in a preliminary period of from 12 to 17 days and there was an experimental period of from 2 to 3 weeks during which the conditioned reflex was established. The results are tabulated and there are 2 graphs. The foods used were: normal, consisting of, per cent., yeast 3, meatmeal 5, casein 9, fat 10, cod liver oil 1, salt mixture of Sós (*Kiserl. Orvostud.*, 1951, **3,** 67) 4, starch 68; high-protein, no meatmeal, casein 37, starch 45, other items as before; low-protein, no meatmeal or casein, starch 82; high in saturated fats, beef suet 25, starch 53; high in unsaturated fats, oil 25; low in B vitamins, no yeast, meatmeal and casein extracted with dilute acid by the method of Sure (Abst. 254, Vol. 3); vitamin-enriched, normal with, per 100 g., vitamin A 1·5 mg., or vitamin B_1 1 mg., or riboflavin 1 mg., or vitamin B_6 1 mg., or vitamin "N" 50 mg., or vitamin B_1 0·5, riboflavin 0·5, vitamin B_6 0·5 and vitamin

"N" 18 mg. The vitamins were mixed with the foods, which were made up daily with 40 per cent. spring water.

In experiment 1 the choice of foods offered was between normal, high-protein, low in B vitamins and high in B vitamins. During establishment of the conditioned reflex, as shown by the animal's reaction time, consumption of the food rich in B vitamins rose significantly compared with that of the rats fed in their cages; it tended to fall once the reflex was established. The same was found in experiment 2, in which the choice of foods was between normal, high in B vitamins, high in vitamin A, high in saturated fats and high in unsaturated fats; with nutrients other than B vitamins, no trend was found. In experiment 3, in which normal food was offered with and without added vitamin B_1, riboflavin, vitamin B_6 or vitamin "N", no significant difference was found between the two groups of rats or between vitamins, either because the rats could not distinguish between them or because the amounts added, 6 times the normal requirement, were too large. In experiment 4 the rats were given the food low in B vitamins throughout, without choice, and establishment of the conditioned reflex was much slower than in any of the previous tests and the reaction times were longer.

The results are discussed in conjunction with those of an earlier experiment (Abst. 1933, Vol. 25). It is suggested that stress on the central nervous system increases the requirement for B vitamins. Further experiments are planned.—W. M. Deans.

4385

ARNRICH, L., HURLEY, L. S., FORKER, B. R. and MORGAN, A. F. **Response to stress by riboflavin-deficient and pantothenic acid-deficient dogs.** *Amer. J. Physiol.*, 1956, **184,** 515–520. [Dept. Home Econ., Univ. California, Berkeley.]

Young dogs were given a purified diet complete or without riboflavin or pantothenic acid for 2 weeks, and their blood sugar values were measured before, immediately after, and 1 and 2 hr. after, swimming in a tank at 25° C. for 25 min. The swimming test was repeated at intervals of 2 weeks until the deprived dogs died or were killed. The rise of blood sugar in response to stress was greatest in riboflavin-deficient dogs, and an abnormal fall occurred 2 hr. after exercise in dogs deprived of riboflavin or pantothenic acid. Restriction of food intake in dogs on the complete diet did not produce the effects produced by deprivation of riboflavin or pantothenic acid. Adrenal cortical extract had a compensatory effect and tended to counteract the rise in blood sugar after swimming in normal dogs and in dogs deprived of pantothenic acid but not in those deprived of riboflavin. In normal dogs given adrenaline, blood sugar and lactic acid rose as they were found to do after swimming stress. Of the dogs that collapsed in hypoglycaemic coma during deprivation, those deprived of pantothenic acid could be restored by adrenal cortical extract, but those deprived of riboflavin could not. Differences in the mechanism by which failure of the adrenal and pituitary cycle occurred in the two types of vitamin deficiency are discussed.—A. M. Copping.

FRIEND, W. G. and PATTON, R. L. **Studies on vitamin requirements of larvae of the onion maggot, *Hylemya antiqua* (Mg.), under aseptic conditions.** *Canad. J. Zool.*, 1956, **34,** 152–162. [Veg. Insect Sect., Entomol. Lab., Ottawa.]

The basal medium contained, in mg. per ml., agar 20, ribonucleic acid 1, inosine 0·03, thymine 0·004, cholesterol 0·1, dextrose 15, mineral mixture U.S.P. XIII, No. 2, 2 and amino acid mixture 24·21, and vitamin mixture 77·96 μg. per ml. The amino acid mixture provided 19 amino acids.

Eggs of the onion fly from adults fed on honey and brewer's yeast were disinfected in formalin and added to tubes of the medium, unmodified or with single vitamins omitted. Development of the larvae was studied. Biotin, pantothenic acid, choline, folic acid, pyridoxine, riboflavin, nicotinic acid and vitamin B_1 were essential for normal growth and development. Vitamin B_{12}, thioctic acid and coenzyme A each gave a greater number of pupae and a better ratio of male to female flies, but were not indispensable. The effects of omitting different vitamins became apparent at different stages of development. From all the 1016 eggs used in the experiment only 52 adults were obtained, and when they were caged together and fed on honey and brewer's yeast only 4 eggs were laid.—D. Duncan.

4387

MORGAREIDGE, K. **The effect of light on vitamin retention in enriched white bread.** *Cereal Chem.*, 1956, **33,** 213–220. [Food Res. Labs., Inc., 48–14 Thirty-Third St., Long Island City 1, N.Y.]

Bread wrapped in plain or printed cellophane or waxed paper did not show any loss of vitamin B_1, riboflavin or nicotinic acid within 5 days when displayed as is usual in retail stores and exposed to intermittent general illumination of up to 100 foot-candles.—F. C. Aitken.

4388

KNAUT, T. Zawartość tiaminy i ryboflawiny w mleku surowym i gotowanym. [**The vitamin B_1 and riboflavin content of raw and boiled**

milk.] *Rocz. Nauk rol.* [*B*], 1955, **70,** 197–205. [Zakł. Technol. Mleczarstwa SGGW, Warsaw.] Russian and English summaries.

In raw milk the average content, in mg. per cent., was of vitamin B_1 0·0417, range 0·038 to 0·045, and of riboflavin 0·192, range 0·169 to 0·209. After boiling for 2 min. the average content of vitamin B_1 was 0·0386 and of riboflavin 0·187. The percentage lost through boiling was of vitamin B_1 7·43 and of riboflavin 2·6. The values found agreed well with those quoted in the literature. (From English summary.)—T. D. Bell.

4389

COVER, S. and SMITH, W. H. (Jr.) **Effect of moist and dry heat cooking on vitamin retention in meat from beef animals of different levels of fleshing.** *Food Res.*, 1956, **21,** 209–216. [Texas Agric. Exp. Stat., College Station.]

Vitamin B_1 and nicotinic acid were estimated, before and after cooking, in thin and thick cuts of beef from animals killed off pasture and out of the feedlot. There was no consistent difference in content or retention of the vitamins between pasture and feedlot animals. Broiled steaks retained higher percentages of vitamin B_1 and nicotinic acid than braised steaks. Oven roasts retained less vitamin B_1 and more nicotinic acid than pot roasts. It was not possible to generalise about the relation between vitamin B_1 retention and cooking temperature, cooking time or moisture content of cooked meat.—F. C. Aitken.

GREGORY, B. R., WILDER, O. H. M. and OSTBY, P. C. **Studies on the amino acid and vitamin composition of feather meal.** *Poultry Sci.*, 1956, **35,** 234–235. [Div. Animal Feeds, Amer. Meat Inst. Found., Chicago, Ill.]

Thirteen amino acids and 4 vitamins were estimated in 5 samples of feather meal prepared by processing under steam pressure and containing about 87 per cent. protein. The amino acid appeared to be relatively stable to processing, with the exception of arginine, phenylalanine, *iso*leucine and cystine, but only cystine showed considerable loss. The average content, in mg. per lb., of riboflavin, nicotinic acid and pantothenic acid was 0·88, 7·85 and 3·68, respectively. Vitamin B_{12} activity, estimated with *Lactobacillus leichmannii*, was 32·2 μg. per lb.—E. M. Cruickshank.

TAKEUCHI, Y., OKUDA, K., HAYAKAWA, S. and MIZUHARA, S. **The active center of thiamine.** *J. Biochem., Tokyo*, 1955, **42,** 93–97. [Dept. Biochem., Med. Sch., Okayama Univ.]

The sulphydryl compounds cysteine, thioglycollic acid, thioglycollic acid-pyruvic acid addition compound, thiophenol, thiophenol-pyruvic acid addition compound, and O,S-diacetylthiamine did not catalyse formation of acetoin from pyruvate and acetaldehyde in experimental conditions in which vitamin B_1 had previously been shown to be active. Sodium cyanide did catalyse acetoin formation but was less active than vitamin B_1.—M. H. Pierce.

4396

KIESSLING, K. H. **Studies on thiamine triphosphate.** *Biochim. biophys. Acta*, 1956, **20**, 293–298. [Inst. Zoophysiol., Upsala.]

Analysis by chromatography on paper of the phosphates of vitamin B_1 formed when baker's yeast was incubated with vitamin B_1, thiamine and pyrophosphate showed the presence of a substance whose behaviour on the chromatogram corresponded with that of synthetic vitamin B_1 triphosphate; vitamin B_1 diphosphate and monophosphate were present also. Vitamin B_1 triphosphate was hydrolysed by potato apyrase in the same way as adenosine triphosphate, which suggested that the arrangement of the phosphate groups in the two compounds was similar. The triphosphate did not replace cocarboxylase in a purified pyruvate decarboxylating system unless it had previously been incubated with apyrase to remove one phosphate group.—A. M. Copping.

FREI, J. Oxydation phosphorylante et carences en vitamines du groupe B. 1. Carence en aneurine. [**Phosphorylating oxidation and deficiencies of B group vitamins. 1. Vitamin B_1 deficiency.**] *Helv. physiol. pharm. Acta*, 1956, **14**, 59–69. [Méd. Clin., Univ. Lausanne.] English summary.

1. Oxidative phosphorylation was measured with ^{32}P according to methods developed by Krebs and his colleagues (*Biochem. J.*, 1953, **54**, 107) in tissues from normal rats and rats deprived of vitamin B_1. The decrease in phosphorylation in the liver from deprived rats was greater than could be accounted for by the small increase which occurred in adenine triphosphatase. There was no difference in the nitrogen content of the liver from normal and deprived rats. In homogenates of liver of deprived rats, the rate of phosphorylation was not affected by addition of vitamin B_1 or cocarboxylase, but the activity was found to have been recovered when deprived rats had been given vitamin B_1 for 2 or 3 days. The bearing is discussed of the observations on the view that the fundamental lesion of the liver in vitamin B_1 deficiency is a defect of the mitochondria.—A. M. Copping.

4398

ARGYRIS, T. S. **Loss of sebaceous glands in skin of thiamine-deficient mice.** *Science*, 1956, **123**, 634–635. [Dept. Anat., Harvard Med. Sch., Boston, Mass.]

Mice were given purified diets with or without vitamin B_1 21 days after the plucking of club hairs, ready to be shed, had initiated a new wave of hair growth. Biopsies of specimens of skin were taken 7, 14 and 21 days after the dietary change. No difference was detected after 7 days but after 14 days atrophy of skin follicles, resulting from decrease in the size of the panniculus adiposus, was seen in the mice deprived of vitamin B_1. The sebaceous glands were normal at that stage, but at later stages atrophic changes increased in the skin and sebaceous glands, and lipids could not be demonstrated in the remnants of the glands. Pair-fed mice given vitamin B_1 showed loss of the panniculus adiposus, and decrease in the thickness of the epidermis and size of the follicles, but no loss of the sebaceous glands.—A. M. Copping.

4399

TERROINE, T. Sur le rôle vicariant de l'acide ascorbique en carence B_1. [**Substitutive role of ascorbic acid in vitamin B_1 deficiency.**] *C.R. Acad. Sci.*, 1956, **242**, 2767–2769.

Rats receiving a massive supplement of 3 per cent. of ascorbic acid in a diet without vitamin B_1 continued to grow and survived without sign of polyneuritis for longer than rats with no supplement. The vitamin B_1 content of the liver fell rapidly whether ascorbic acid was given or not. Food consumption was much greater in animals given ascorbic acid, and prolongation of life was thought to be due to the maintenance of a satisfactory intake of food.—A. M. Copping.

BOROS, É. and SZAMOSI, A. Aneurinbedarf von Ratten bei Ausbau bedingter Reflexe. [**Vitamin B_1 requirement of rats during establishment of conditioned reflexes.**] *Acta physiol. hung.*, 1956, **9**, *Suppl.*, 50–51. [2. Med. Klin., Med. Univ., Budapest.]

4401

HÄNDEL, M., BOROS, É., HERMANN, GY. and WEISZ, P. Wirkung von Aneurin auf die experimentelle neurogene Hypertonie von Ratten. [**Effect of vitamin B_1 on experimental neurogenic hypertension in rats.**] *Acta physiol. hung.*, 1956, **9**, 253–260. [Pathophysiol. Inst., Med. Univ., Budapest.] Russian summary.

The rise of blood pressure induced in rats by light, noise and electrical stimuli (Abst. 1933, Vol. 25) was less when 0·2 mg. vitamin B_1 per 100 g. bodyweight was injected; 1·5 mg. had no greater effect. In rats deprived of vitamin B_1 experimental hypertension was induced by the same means as readily as in normal animals. When hypertension had been induced, injection of 2 mg. vitamin B_1 per 100 g. weight reduced blood pressure, which was at its lowest after 2 hr.; it had regained the former high value after 5 hr. In rats with normal blood pressure injection of vitamin B_1 had no effect.—A. M. Copping.

4402

GUILHON, J., OBRY, J. and QUEINNEC, G. Reproduction expérimentale du syndrome hémorragique des jeunes bovidés bretons par ingestion de fougère aigle de la région parisienne. [**Experimental production of the haemorrhagic syndrome of young Breton cattle by the consumption of bracken fern from the neighbourhood of Paris.**] *Bull. Acad. vét. France*, 1955, **28,** 457–462 (with discussion 463).

Three young calves were brought from different parts of Brittany to Alfort at about 6 weeks of age and given a controlled diet of mixed hay, barley, and mineral supplement for a month before bracken fern was added to the feed, as 1 kg. daily of green bracken which was brought in fresh each week. All the animals were normal before bracken was eaten but within a month rise of temperature, haemorrhages on mucous surfaces and agranulocytosis were recorded. The animals died in from 6 to 9 weeks with general signs closely resembling those reported in animals suffering from bracken poisoning in Brittany.

The toxicity of bracken is discussed with reference to the possible effects of tannins, potassium and thiaminase.—A. M. Copping.

4403

SUOMALAINEN, H. and AXELSON, E. **Effect of thiamine on the rate of fermentation of zymohexoses and of maltose by baker's yeast.** *Biochim. biophys. Acta*, 1956, **20,** 315–318. [Res. Labs., State Alcohol Monopoly, Helsinki.]

Vitamin B_1 added to a synthetic medium stimulated production of CO_2 from glucose, fructose, mannose and maltose by commercial baker's yeast, but did not abolish the induction period which characterises the fermentation of maltose by yeast.

A. M. Copping.

4404

SUZUOKI-ZIRO. **Thiamine uptake by yeast cells.** *J. Biochem., Tokyo*, 1955, **42,** 27–39. [Pharmacol. Sect., Res. Lab., Takeda Pharmaceutical Industries, Ltd., Osaka.]

Cells of *Saccharomyces cerevisiae* were incubated at 27° C. and vitamin B_1 was estimated by the thiochrome method with cyanogen bromide and a Klett fluorimeter. Uptake of O_2 and production of CO_2 were measured in a Warburg apparatus. Decrease in the concentration of vitamin B_1 in the incubation medium was established as being a measure of the vitamin B_1 taken up by the cells.

In presence of glucose, the cells took up vitamin B_1 after a lag period of from 10 to 15 min. in aerobic and anaerobic conditions. The uptake depended on the concentration of glucose, but in presence of excess glucose the rate was not influenced by the initial concentration of vitamin B_1. The reaction was accelerated by K ions. The rate of uptake of vitamin B_1 by cells previously incubated with glucose bore a linear relation to lapse of time, and there was no lag.

The optimum *p*H for uptake of vitamin B_1 was from 4·5 to 5·0. The effect of several inhibitors tested showed that uptake of vitamin B_1 was closely related to the metabolism of carbohydrate and phosphate. Derivatives of vitamin B_1 of the thiol type were not taken up by yeast cells.

M. H. Pierce.

RIBOFLAVIN

4405

YAGI, K. and MATSUOKA, Y. **Separatory determination of riboflavin nucleotides by paper electrophoresis.** *J. Biochem., Tokyo*, 1955, **42,** 757–762. [Dept. Biochem., Sch. Med., Univ. Nagoya.]

Riboflavin, flavin mononucleotide and flavin dinucleotide were separated by electrophoresis in the dark on paper buffered at *p*H 8·0. The substances were located by their fluorescence in ultraviolet light. The strips of paper were separated, and the substances were eluted with water and estimated with a Beckman spectrophotometer by their absorption at 450 mμ.—E. M. Hume.

4406

PLAUT, G. W. E. and BROBERG, P. L. **Biosynthesis of riboflavin. 3. Incorporation of C^{14}-labeled compounds into the ribityl side chain.** *J. Biol. Chem.*, 1956, **219,** 131–138. [Inst. Enzyme Res., Univ. Wisconsin, Madison.]

For parts 1 and 2 see Absts. 423, 1940, Vol. 25.

Ashbya gossypii was grown in a medium to which was added glucose-1-^{14}C, glucose-2-^{14}C, glucose-6-^{14}C or acetate-1-^{14}C or acetate-2-^{14}C. The riboflavin formed was measured and examined to find the amounts of ^{14}C from acetate or glucose incorporated into the ribityl side chain. It appeared that the hexose monophosphate pathway was not the only one ; transketolase and aldolase pathways were used also.—A. M. Copping.

4407

SYMEONIDIS, A. and MULAY, A. S. **Histopathology of the adrenal glands of rats fed a low-protein, low-riboflavine diet alone, or with *p*-dimethylaminoazobenzene.** *J. Nat. Cancer Inst.*, 1956,

16, 1163–1179. [Nat. Cancer Inst., Bethesda, Md.]

A histological study was made of the adrenal glands of rats receiving a semi-synthetic diet of low-protein and low-riboflavin content with or without addition of the carcinogen *p*-dimethylaminoazobenzene. If deoxycorticosterone acetate was given or the adrenal glands were removed, neoplastic lesions did not develop in the liver when the carcinogen was given. The semi-synthetic diet by itself induced changes in the adrenal glands, which included increase in the width of the glomerulosa, fasciculata and transitional zones by proliferation and enlargement of the cells, increase of lipoid material in the cells and degeneration in the reticularis zone ; the changes were more pronounced when the carcinogen was added. The adrenal cortex was atrophic and almost free of lipoid material in rats given deoxycorticosterone as well as the carcinogen.—A. M. Copping.

4408

WASE, A. W. **The biological half-life of riboflavin-C^{14} in the liver of normal rats and rats fed 2-acetylaminofluorene.** *Arch. Biochem. Biophys.*, 1956, **61,** 174–178. [Div. Biol. Chem., Hahnemann Med. Coll., Philadelphia, Pa.]

Daily injections of riboflavin labelled with ^{14}C were given for 28 days to 30 adult rats, fed on a semi-synthetic diet containing 0·266 mg. riboflavin per 100 g. dry weight. Six were then killed and the radio-activity of the liver riboflavin was estimated. Acetylaminofluorene, 0·03 per cent. in the diet, was given to 12, and 12 others received the basal diet alone. Animals were killed after 1, 2, 4 and 5 days and the specific activity of the liver riboflavin was measured. In rats on the basal diet alone the biological half-life of riboflavin-^{14}C was 6·53 days. Acetylaminofluorene reduced the biological half-life to 1·09 day. Acetylaminofluorine in the diet appeared to increase the metabolic turnover of riboflavin and might thus cause deficiency unless more riboflavin was given.

A. M. Copping.

4409

SIBBALD, I. R. and BOWLAND, J. P. **Supplemental riboflavin and a feed flavour in creep feed rations for swine.** *Canad. J. Agric. Sci.*, 1956, **36,** 19–26. [Dept. Animal Sci., Univ. Alberta, Edmonton.]

Extra riboflavin or a flavouring agent composed of anise and molasses added to a ration composed of wheat, oats, meatmeal, soya bean oilmeal, sugar and vitamins had no significant effect on the amount of feed eaten or the growth rate of sucking pigs receiving it as creep feed from the age of 2 weeks. There were considerable seasonal variations in the amount of creep feed eaten and in the weaning weight of sucking pigs. The riboflavin content of the basal creep feed was 1·5 g. per ton or 0·75 mg. per lb., which appeared to be sufficient.—A. M. Copping.

ORUNESU, M. and FORNAINI, G. Sul meccanismo della glicogenolisi epatica da forti dosi di nicotinamide. [**The mechanism of glycogenolysis in the liver caused by large doses of nicotinamide.**] 1. Comportamento della " glucoso-6-fosfato-fosfatasi ". [**1. Behaviour of glucose-6-phosphate phosphatase.**]

FORNAINI, G. and ORUNESU, M. 2. Comportamento della " glucoso-6-fosfato-deidrogenasi ". [**2. Behaviour of glucose-6-phosphate dehydrogenase.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31,** 985–986 ; 986–987. [Ist. Chim. Biol., Univ. Sienna.]

1. Glycogen in the liver and the amount of inorganic phosphate liberated from β-glycerophosphate at *p*H 6·8 by liver homogenates were estimated for 15 pairs of rats of which 1 in each pair was given 100 mg. nicotinamide per kg. bodyweight 4, 8 or 12 hr. before being killed. The large decrease in liver glycogen occurred as usual after nicotinamide (see Abst. 3522, Vol. 25), but there was no difference in the amount of inorganic P liberated, showing that there was no increase in the activity of glucose-6-phosphate phosphatase.

2. With the same technique and 5 pairs of rats not given and given nicotinamide 8 hr. previously, glucose-6-phosphate dehydrogenase in homogenates of the liver was measured by their capacity to reduce triphenyltetrazolium chloride on incubation with and without glucose-6-phosphate. The mean

value for 10 tests in mg. triphenyltetrazolium chloride per 100 mg. tissue incubated at 37° C. for 25 min. was 0·38 for those given nicotinamide and 0·25 for those not given it.—E. M. Hume.

4412

SUNDARAM, T. K., MOUDGAL, N. R. and SARMA, P. S. **Influence of thyroid hormone on nicotinamide metabolism in the rat.** *Biochim. biophys. Acta*, 1956, **20**, 413–414. [Biochem. Lab., Univ. Madras.]

Groups of 4 adult rats were given methylthiouracil or desiccated thyroid or no addition for from 5 to 7 weeks. At the end of that time excretion of N^1-methylnicotinamide in response to an injection of nicotinamide was raised in hypothyroid and reduced in hyperthyroid animals. The results are discussed with reference to the role of thyroid hormone in methylating processes.—A. M. Copping.

KAVANAU, J. L. and BÁNHIDI, Z. G. **Studies of the metabolism of B-vitamins and related compounds in embryonic sea urchin development. 2. The niacin group of factors.** *Exp. Cell. Res.*, 1956, **10**, 415–423. [Wenner-Gren Inst. Exp. Biol., Univ. Stockholm.]

Lactobacillus arabinosus was used to measure the free nicotinic acid components in extracts made with acetone and HCl from eggs and embryos of the sea urchin; very considerable amounts were found. The changes in activity of the nicotinic acid group of compounds during development were related to changes in the insoluble protein fraction of the embryo but the amounts of nicotinic acid derivatives present were greater than would be expected if their sole function was that of precursor for pyridine nucleotide coenzymes.

VITAMIN B_6 (PYRIDOXINE, ADERMIN)

4414

SAKURAGI, T. and KUMMEROW, F. A. **The biological utilization of various fat-soluble esters of pyridoxine and 4-desoxypyridoxine by rats.** *J. Nutrition*, 1956, **58**, 557–568. [Dept. Food Technol., Univ. Illinois, Urbana.]

In tests with rats receiving optimum and suboptimum amounts of pyridoxine as the hydrochloride, tri-acetate, tripalmitate and trilinoleate the different esters were as active as the hydrochloride. The esters were tested also as antidotes to deoxypyridoxine and its esters. They appeared to be less rapidly absorbed than free pyridoxine and were retained in the body for a longer time.

Pyridoxine tribenzoate, tri-*p*-nitrobenzoate and tri-*m*-nitrobenzoate showed biological activity, but that of the nitrobenzoates was small, probably because of their high melting-points.

A. M. Copping.

PUSZTAI, A. **Enzymatic synthesis of pyridoxalphosphate.** *Acta physiol. hung.*, 1956, **9**, 381–391. [Inst. Biochem., Hungarian Acad. Sci., Budapest.] Russian summary.

The synthesis by *Streptococcus faecalis* of pyridoxal phosphate from pyridoxal ethylacetal hydrochloride and adenosine triphosphate was studied by paper chromatography. The active enzyme synthesised by *S. faecalis* was found to be identical with chemically synthesised pyridoxal-5-phosphate. It was calculated from measurements of tyrosine decarboxylase activity that about 5 per cent. of the added pyridoxal was converted to the phosphate in the conditions of the experiment.

ROSS, M. L. and PIKE, R. L. **The relationship of vitamin B_6 to protein metabolism during pregnancy in the rat.** *J. Nutrition*, 1956, **58**, 251–268. [Dept. Foods Nutrit., Pennsylvania State Univ., University Park.]

Rats maintained before and during pregnancy on diets adequately supplemented with pyridoxine gained over 100 g. in weight; those depleted of vitamin B_6 before mating gained less weight during pregnancy even with an adequate intake of pyridoxine, still less if pyridoxine was restricted or withheld, and least if they were given deoxypyridoxine. Food intake during pregnancy was related to pyridoxine intake and less nitrogen was retained by depleted than by non-depleted rats. Rats given deoxypyridoxine showed poor N retention.

The weight and N content of the liver relative to bodyweight were greater in rats receiving

deoxypyridoxine than in those given adequate amounts of pyridoxine. Pyridoxine given to depleted animals reduced the protein content of the liver but not to the values found in non-depleted animals.

Young from rats depleted of vitamin B_6 before mating were of low birthweight even when pyridoxine was given during pregnancy.

KOTAKE, YAHITO and NOGAMI, K. **Research on xanthurenic acid. 14. Effect of 5-hydroxyanthranilic acid on the formation and conjugating reaction of xanthurenic acid in albino rat.**

KOTAKE, YAHITO, INADA, T., MATSUMURA, Y., INOUYE, K. and TAKAMORI, F. **15. Adrenalectomised albino rats and their tryptophan metabolism.** *Proc. Japan Acad.*, 1955, **31**, 582–586; 587–591. [Biochem. Dept., Wakayama Med. Coll.]

For part 13 see Abst. 3037, Vol. 26.

14. Rats weighing about 200 g. were given a diet of, per cent., casein 22, salt mixture 6, agar 3, yeast 2, butter 10, sugar 5 and starch 52. They were given in addition 0·4 g. Na butyrate and 0·1 g. tryptophan by mouth; at the same time some were given an injection of 0·2 mg. 5-hydroxyanthranilic acid per kg. bodyweight, and a second injection on the next day but one.

In the 24-hr. urine the average amount of xanthurenic acid was 8·29 mg. (5 tests) for the rats not given hydroxyanthranilic acid, and 2·07 mg. (10 tests) for those given it. The administration of hydroxyanthranilic acid prevented the hyperglycaemia and glycosuria caused by giving tryptophan and Na butyrate. Paper chromatography showed that there was much less 3-hydroxykynurenine and its conjugated compounds and xanthurenic acid in the urine of the rats given hydroxyanthranilic acid than in the urine of those not given it, which contained conjugated compounds of xanthurenic acid such as anthranilic acid glycuronide and N^{α}-acetylkynurenine. Estimation of kynurenic acid showed the amount in the urine of the rats given hydroxyanthranilic acid to be about double that in the urine of those not given it.

Similar rats having the same diet were given a hypodermic injection of 10 mg. xanthurenic acid in ammoniacal solution, and one group was given 0·4 g. Na butyrate by mouth. The average amount of ethereal sulphate of xanthurenic acid in the 24-hr. urine of those given Na butyrate was about half that in the urine of those not given it. With the same technique, 2 injections of 10 mg. methionine or 100 μg. 5-hydroxyanthranilic acid counteracted the effect of Na butyrate in inhibiting the conjugation of xanthurenic acid.

15. In similar rats having the same diet, xanthurenic acid in the 24-hr. urine after administration of 10 g. tryptophan was reduced to less than half when the pituitary or adrenal glands had been removed, and paper chromatography showed the presence of N′-formylkynurenine and 3-hydroxykynurenine, not found in the urine of intact rats.

Liver homogenates were prepared from normal rats and rats from which the adrenal glands had been removed 5 days earlier; some of the latter had received injections of 3 mg. cortisone daily for the 5 days. Supernatant fluid from the homogenates, suitably buffered, was incubated with tryptophan for 3 hr., and kynurenine, anthranilic acid and xanthurenic acid were estimated in the preparations. All 3 substances were much less than the normal in the adrenalectomised rats but were much greater than the normal in the adrenalectomised rats given cortisone.

It is therefore concluded that the adrenal and pituitary glands are indispensable for the formation of kynurenic acid and xanthurenic acid, respectively, through the mechanism of transaminase.—E. M. Hume.

UMEBACHI, Y. and TSUCHITANI, K. **The presence of xanthurenic acid in the fruit-fly, *Drosophila melanogaster*.** *J. Biochem., Tokyo*, 1955, **42**, 817–824. [Dept. Biol., Fac. Sci., Univ. Kanazawa.]

Fruit flies of the wild type and of 11 strains of eye-colour mutants were reared on a liquid medium. The heads of 300 flies of the wild type of both sexes were analysed together, but the bodies of the sexes were kept separate. The ethanol extract of the heads, on paper electrophoresis, yielded 2 spots giving a positive diazo reaction. One of the spots corresponded with 3-hydroxykynurenine and the other represented an unidentified substance which was investigated. In its R_F value, colour reaction, behaviour on paper electrophoresis and ultraviolet absorption spectrum it resembled xanthurenic acid. No sex difference with regard to it was found. The substance was absent from 7 of the mutant strains from which 3-hydroxykynurenine also was absent, but was present in 2 strains which were without 3-hydroxykynurenine. Three strains were without kynurenine as well. Xanthurenic acid when present was more abundant in the head than in the body.—E. M. Hume.

4423

SZÖRÉNYI, E., ELÖDI, P., SZÖRÉNYI, B. and PUSZTAI, A. Zitrulliniminase, ein neues kristallinisches Pyridoxalproteid. Vorläufige Mitteilung. [**Citrulliniminase, a new crystalline pyridoxal protein. Preliminary note.**] *Acta physiol. hung.*, 1955, **7**, 163–165. [Inst. Biochem., Hungarian Acad. Sci., Budapest.]

A crystalline preparation of citrulliniminase obtained from two kinds of crab, *Potambius astacus* and *P. leptodactylus*, was shown to require pyridoxal-5-phosphate or other codecarboxylase preparation as coenzyme for conversion of citrullin to arginine. The relation between citrulliniminase and pyridoxal protein complex will be discussed at length in a further publication.—A. M. Copping.

HOLTZ, P., STOCK, K. and WESTERMANN, E. Über den Einfluss des Thyroxins und des Hungerns auf die Aktivität der Monoaminoxydase und Dopadecarboxylase der Leber. [**Effect of thyroxine and starvation on the activity of monoaminooxidase and dopa decarboxylase in the liver.**] *Arch. exp. Pathol. Pharmakol.*, 1956, **228**, 322–330. [Pharmakol. Inst., Univ. Frankfurt a.M.] English summary.

Guineapigs, rabbits and rats were treated with thyroxine or triiodothyronine for from 4 to 22 days; there was considerable loss of weight from both body and liver. The monoaminooxidase activity of liver extracts from the animals was increased or not significantly altered compared with the activity of extracts from the livers of untreated animals, whether activity was expressed per g. wet or dry weight or per mg. total N. Similar results were obtained with starved guineapigs. In contrast, the dihydroxyphenylalanine (dopa) decarboxylase activity of the same liver extracts was significantly reduced compared with that of extracts from normal animals. Pyridoxal phosphate (coenzyme) added to the extracts increased the dopa decarboxylase activity of extracts from the liver of normal rats and gave a still greater rise in activity of extracts from the livers of starved rats, but almost no increase in the activity of extracts from animals treated with thyroid. Similar results were obtained with guineapigs.—L. Wills.

4425

HOLDEN, J. T. **Inhibition of phenylalanine and tyrosine synthesis in *Streptococcus faecalis* and *Lactobacillus arabinosus* by α-keto acids.** *Arch. Biochem. Biophys.*, 1956, **61**, 128–136. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

The growth responses of *Streptococcus faecalis* and *Lactobacillus arabinus* in media deficient in tyrosine or phenylalanine were studied when pyridoxamine and amino and α-keto acids were added. In the absence of tyrosine or phenylalanine, pyridoxamine was a powerful growth stimulant. In the absence of tyrosine, *p*-hydroxyphenylpyruvic acid stimulated, and phenylpyruvic acid inhibited, growth even with added pyridoxamine. In the absence of phenylalanine the roles of *p*-hydroxyphenylpyruvic acid and phenylpyruvic acid were reversed. The results are discussed with reference to the importance of pyridoxamine in transamination reactions with α-keto acids.—A. M. Copping.

4426

GAFFURI, P. and CREMA, A. Esperienze sull'interferenza tra vitamina B_6 e idrazide dell'acido isonicotinico. [**Interference between vitamin B_6 and *iso*nicotinic acid hydrazide.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31**, 960–962. [Ist. Farmacol., Univ. Pavia.]

Pyridoxine hydrochloride was without effect on the inhibition exerted by *iso*nicotinic acid hydrazide on the oxygen consumption of *Mycobacterium tuberculosis* or of homogenates of rabbit's lung.

ANGELICO, R. and QUINTILIANI, M. Rapporti dell' acido pantotenico con la funzione surrenale. [**Relation of pantothenic acid to adrenal function.**] *Rend. Ist. Super. Sanità, Rome*, 1955, **18**, 1278–1294. [Lab. Biol., Ist. Super. Sanità, Rome.] French, English and German summaries.

The subject is reviewed, the authors' own recent work being included (Title 4297, Vol. 23; Absts. 3544, 3545, 3546, Vol. 25; and the 3 following Absts.).

The tentative conclusion is reached that in pantothenic acid deficiency the adrenal glands synthesise corticosteroids with difficulty, but the difficulty becomes apparent only in emergency when the demand is increased.—E. M. Hume.

4432

ANGELICO, R. and QUINTILIANI, M. Effetto della carenza di acido pantotenico sulla produzione *in vitro* di corticosteroidi da parte di ghiandole surrenali di ratto. [**Effect of pantothenic acid deficiency on the production of corticosteroids *in vitro* by the adrenal glands of the rat.**] *Rend. Ist. Super. Sanità, Rome*, 1955, **18**, 1269–1273. [Lab. Biol., Ist. Super. Sanità, Rome.] French, English and German summaries.

Male rats weighing from 35 to 40 g. were given a complete diet with or without pantothenic acid. After from 30 to 50 days, when weight increase was slackening, they were killed and the adrenal glands were removed. Preparations of them were incubated in Krebs Ringer phosphate with 0·2 per cent. glucose with and without 0·1 I.U. adrenocorticotropic hormone in 2 ml. medium. After incubation, corticosteroids in the medium were estimated by their spectral absorption in ultraviolet light and by colorimetric measurement of formaldehyde formed by oxidation with periodic acid as described elsewhere (*Rend. Ist. Super. Sanità, Rome*, 1955, **18**, 1261). There was no significant difference between the amounts of corticosteroids formed by adrenal tissue from normal and deprived rats unless adrenocorticotropic hormone was included in the incubation medium. Adrenal tissue from nondeprived then showed a

large increase in the corticosteroids formed, as measured with ultraviolet light, but adrenal tissue from deprived rats was incapable of making any such response.—E. M. Hume.

4433

QUINTILIANI, M. Eliminazione urinaria di corticosteroidi nel ratto carente di acido pantotenico. [**Urinary excretion of corticosteroids in the rat deprived of pantothenic acid.**] *Rend. Ist. Super. Sanità, Rome*, 1955, **18,** 1274–1277. [Lab. Biol., Ist. Super. Sanità, Rome.] French, English and German summaries.

Total reducing corticosteroids were estimated with tetrazolium blue in the urine of 2 groups of 12 rats, maintained from the bodyweight of 50 g. on a diet complete except for pantothenic acid. One group received the same diet with 100 mg. Ca pantothenate per kg. added. In the urine excreted in 24 hr., there was no significant difference after 10, 20 or 30 days of the diets between the deprived and the non-deprived group in their excretion of corticosteroids.—E. M. Hume.

4434

ANGELICO, R. and QUINTILIANI, M. Studi sulla gluconeogenesi nel ratto florizinato, carente di acido pantotenico. 3. Azione del cortisone e dell'acido pantotenico sulla eliminazione urinaria di glucosio e azoto. [**Glyconeogenesis in phloridzinised rats deprived of pantothenic acid. 3. Effect of cortisone and of pantothenic acid on urinary excretion of glucose and nitrogen.**] *Rend. Ist. Super. Sanità, Rome*, 1955, **18,** 1253–1260. [Lab. Biol., Ist. Super. Sanità, Rome.] French, English and German summaries.

For part 2 see Abst. 3546, Vol. 25.

Groups of from 8 to 15 male rats weighing from 65 to 70 g. were given a complete diet with or without Ca pantothenate. One group of 10 in each series received no further treatment. The adrenal glands were removed from the rest from 5 to 8 weeks after the beginning of the experiment. Three days later, after a 24-hr. fast, all the rats were given a single injection of 50 mg. phloridzin. At the same time in the series with and without pantothenate, one group received no further treatment, one group received a single injection of 1 mg. cortisone acetate, and another group had the same injection of cortisone and a single injection of 8 mg. Ca pantothenate. Urine was collected and glucose, N and ketone bodies were estimated in it. In the rats given phloridzin and deprived of their adrenal glands, whether they were at the same time deprived of pantothenic acid or not, cortisone did not significantly modify the urinary excretion of glucose, N or ketone bodies. When, however, a large dose of Ca pantothenate was given at the same time as the cortisone, the deprived rats showed a considerable increase in urinary excretion of glucose and N.—E. M. Hume.

4435

HAZELWOOD, R. L., BENNETT, L. L. and NELSON. M. M. **Effect of pantothenic acid deficiency on insulin sensitivity and response to ACTH of intact and diabetic rats.** *Endocrinology*, 1956, **58,** 427–434. [Dept. Physiol., Univ. California, Berkeley.]

The response to insulin of intact rats deprived of pantothenic acid was low after 8 weeks, whether they were pair-fed or not, but after 14 weeks' deprivation it was greater than in non-deprived, pair-fed rats. In partly depancreatised rats the degree of glycosuria was not affected by deprivation of pantothenic acid. Their sensitivity to insulin was low after 14 weeks' deprivation, about normal after 19 weeks and above normal after 23 weeks. Such diabetic rats still showed a response to adrenocorticotropic hormone after 140 days' deprivation. It was concluded that the adrenal cortex was overactive during the early stages of pantothenic acid deficiency, but that, in the later stages, activity was less than normal.

4436

BÁNHIDI, Z. G. and KAVANAU, J. L. **Studies of the metabolism of B-vitamins and related compounds in embryonic sea urchin development. 1. Pantothenic acid and *Lactobacillus bulgaricus* factor.** *Exp. Cell Res.*, 1956, **10,** 405–414. [Wenner-Gren Inst. Exp. Biol., Univ. Stockholm.]

Extracts of eggs and embryos of the sea urchin *Paracentrotus lividus* at 22 stages of development were made with acetone and HCl by the methods used in preparations for estimation of amino acids (*Exp. Cell. Res.*, 1954, **6,** 563); free and bound pantothenic acid were estimated microbiologically. There was a remarkable correlation between increase in free pantothenic acid content and periods when new embryonic synthesis of protein was taking place. It was not possible from the results to decide whether the free pantothenates of the sea urchin embryo were independent of coenzyme A metabolism or whether they were involved only in that metabolic process.

4437

GIROUD, A., LEFEBVRES, J., PROST, H. and DUPUIS, R. Malformations des membres dues à des lésions vasculaires chez le foetus du rat déficient en acide pantothénique. [**Malformation of limbs due to vascular lesions in the foetus of rats deprived of pantothenic acid.**] *J. Embryol. Exp. Morphol.*, 1955, **3,** 1–12. [Lab.

Embryol., Fac. Méd., Paris.] English summary.

Female rats kept on a purified diet without pantothenic acid until they showed signs of deficiency mated and produced young. Of 224 foetuses taken between the thirteenth and the twenty-first day of gestation from deprived mothers, 22·7 per cent. showed abnormalities. After the sixteenth day deformity of the limbs was very common. Deformities appeared to arise from arrest of circulation with accumulation of blood clots in the tissues. Pressure from the clots caused distortion and degeneration from which a state of ectodactyly followed and, in the most advanced stages, after 18 days of gestation, the epidermis broke down with haemorrhage at the extremities and sometimes amputation of a limb followed.—A. M. Copping.

4438

FISHER, H. and HUDSON, C. B. **Chick viability and pantothenic acid deficiency in the breeding diet—a case report.** *Poultry Sci.*, 1956, **35,** 487–488. [Dept. Poultry Husb., Rutgers Univ., New Brunswick, N.J.]

Chicks from certain hatcheries were listless and weak, and mortality during the first few days after hatching was high. The hatch was good and no pathogen was detected in the chicks. Results of oral administration of single vitamins of the B group suggested that the chicks did not have enough pantothenic acid ; addition of pantothenic acid to the breeding diet, which theoretically was adequate, prevented the disorder. It is suggested that addition of fat to poultry rations increases the requirement of pantothenic acid, a major component of coenzyme A, which is essential for normal metabolism of fat.

E. M. Cruickshank.

4439

FIDANZA, A., RAIMONDI, A. M., ESPOSITO, L. and BONOMOLO, A. Sintesi batterica intestinale dell'acido pantotenico e sua utilizzazione. [**Synthesis of pantothenic acid by intestinal bacteria and its utilisation.**] *Quad. Nutrizione*, 1954, **14,** 159–164. [Ist. Fisiol. Gen., Univ. Rome.] Summaries, French p. 192, English p. 194, German p. 196.

The experimental diet contained, per cent., vitamin-free casein 18, sucrose 67, salts 4, cystine 0·2, cod liver oil 2 and washed butterfat 9, with vitamin B_1, riboflavin, vitamin B_6, nicotinic acid, *p*-aminobenzoic acid, ascorbic acid, choline, inositol, menadione bisulphite, folic acid, biotin, vitamin B_{12}, α-tocopherol and ethyl linoleate, but no pantothenic acid. Three groups of male rats weighing initially 50 g. received for 6 weeks the diet alone, or with, per head daily, 1 mg. calcium pantothenate or 5 mg. crystalline aureomycin. After 6 weeks urine and faeces were collected for 10 days from 5 rats of each group in metabolism cages. The rats given no supplement then had clinical signs of deficiency.

The mean pantothenic acid output in μg. per 24 hr. in faeces and urine, respectively, was for rats given calcium pantothenate $51{\cdot}5 \pm 14$ and 150 ± 30, for rats given no supplement $3{\cdot}5 \pm 2$ and $10{\cdot}0 \pm 6$, and for rats given aureomycin, $20{\cdot}1 \pm 8$ and $50{\cdot}0 \pm 9$. Thus the intestinal bacteria of the deprived rats synthesised some pantothenic acid, though not enough to prevent arrest of growth and signs of deficiency. In the rats given aureomycin growth was only slightly inferior to that of rats given pantothenic acid and there was no other sign of deficiency. The constant appearance of pantothenic acid in the urine, even of deprived rats, showed that it was absorbed.—D. Duncan.

BIOTIN

4440

TERROINE, T. (with BUISSON, L. F. and ROUX, G.) Quelques aspects du métabolisme glucidique dans la carence en biotine. Études *in vivo*. [**Carbohydrate metabolism in biotin deficiency. Studies *in vivo*.**] *Arch. Sci. physiol.*, 1956, **10,** 59–71. [Lab. Biochim. Nutrit., C.N.R.S., Bellevue (Seine-et-Oise).]

Glucose tolerance, sugar and pyruvate in the blood, and glycogen and reducing sugar in the liver and muscle were measured in normal rats and in rats deprived of biotin. In acutely deficient animals increase of blood pyruvate was associated with acidosis and low blood sugar. There was no glycosuria or specific alteration in the liver or muscle glycogen, and glucose tolerance was moderate. Free reducing sugar fell in the liver but not in the muscle. The comparatively mild changes in carbohydrate metabolism in biotin deficiency are discussed with reference to other studies on the subject.—A. M. Copping.

4441

DELOST, P. and TERROINE, T. (with BUISSON, L. F., DELOST, H. and VINCENT, M. A.) Les troubles endocriniens dans la carence en biotine. [**Endocrine disorders in biotin deficiency.**] *Arch. Sci. physiol.*, 1956, **10,** 17–51. [Lab. Physiol. Gén., Sorbonne.]

Measurements of weight increase, skeletal growth

and weight of the adrenal glands, testes and seminal vesicles, and histological studies of the thyroid and adrenal glands and reproductive organs were made in male rats on a diet without biotin, and on a normal diet in unrestricted amount or with food intake restricted to that of the rats deprived of biotin. Development in weight and length was retarded less in simple inanition than in biotin deficiency. The thyroid and adrenal glands appeared normal even at an advanced stage of deficiency, but severe retardation of development was found in all the reproductive tissues. No correlation was found between the development of skin lesions or motor disturbances and the endocrine changes observed.—A. M. Copping.

TRAUB, A. and LICHSTEIN, H. C. **Cell permeability: a factor in the biotin-oleate relationship in *Lactobacillus arabinosus*.** *Arch. Biochem. Biophys.*, 1956, **62,** 222–233. [Dept. Bacteriol. Immunol., Univ. Minnesota, Minneapolis.]

The lag period, characteristic of the growth curve of *Lactobacillus arabinosis* starting from a small inoculum in presence of an optimum amount of biotin, was much less when Tween 40 (polyoxyethylene sorbitan monopalmitate) was included in the medium. Malate also in the medium improved growth of *L. arabinosus* and it seemed possible that traces of biotin in the medium were made available to the organism through changes in its cell permeability. The problem of cell permeability was studied with oleate, of which the growth effect seemed to depend on its making biotin available to the organism. Oleate promoted the growth of *L. arabinosus* only when biotin was present.—A. M. Copping.

FOLIC ACID (PTEROYLGLUTAMIC ACID)

DOCTOR, V. M. and AWAPARA, J. **The incorporation of serine-3-C^{14} into citrovorum factor.** *J. Biol. Chem.*, 1956, **220,** 161–167. [Sect. Exp. Med., Univ. Texas, Houston.]

Optimum conversion of pteroylglutamic acid to citrovorum factor by powder freshly prepared by precipitation with acetone from aqueous extract of chick liver (see Abst. 1997, Vol. 25) was obtained with addition of homocysteine, serine, Mg, diphosphonucleotide and adenosine triphosphate. Formate or formaldehyde instead of serine gave less efficient conversion. When serine-3-^{14}C was used the β-carbon of serine was incorporated into the citrovorum factor. A tentative scheme is put forward for the mechanism of the conversion process.

The citrovorum factor synthesised by the enzyme from chick liver was shown by chromatographic analysis to be similar to naturally occurring leucovorin.

INFANTE, R. and TURCHETTO, E. Influenza della tiroxina sulla proprietà lipotropa dell'acido folico. [**Influence of thyroxine on the lipotropic action of folic acid.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31,** 787–788. [Ist. Chim. Biol., Univ. Bologna.]

Eight groups of 6 rats weighing from 120 to 130 g. were given a diet of, per cent., crude casein 10, sucrose 59, cottonseed oil 10, lard 15, cod liver oil 2·5, salts 3, cholesterol 0·5, inositol 0·3, with vitamins E and K, and B vitamins except vitamin B_{12} and folic acid. One group received no addition and one had 15 mg. folic acid daily. The remainder had daily 1 or 3 mg. folic acid, alone or with 100 or 200 μg. thyroxine. Some were killed after 10 and some after 16 days. After 16 days, the mean value for total lipids in the liver, in g. per 100 g., was 16·2 for the rats given no addition, and from 5 to 6 for the rats given 15 mg. folic acid or 3 mg. folic acid with 100 or 200 μg. thyroxine, but for those given no thyroxine or thyroxine with only 1 mg. folic acid the values ranged from 10·7 to 14·3.—E. M. Hume.

4445

VITALE, J. J., GERSHOFF, S. N., SINISTERRA, L., HEGSTED, D. M. and ZAMCHECK, N. **Effect of aminopterin administration on the metabolism of liver and small intestine of guinea pigs and rats.** *J. Biol. Chem.*, 1956, **220,** 363–368. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Young adult female guineapigs and rats were given subcutaneous injections of 240 μg. aminopterin per kg. bodyweight daily for 4 days, an amount which for rats had been found to be severely toxic and to reduce oxygen uptake by the intestinal mucosa (Abst. 479, Vol. 25). The concentration of folinic acid in the liver of guineapigs and rats was not affected by aminopterin, but that in rat intestine was greatly reduced. In guineapigs the oxygen uptake by the intestinal mucosa appeared not to be affected by aminopterin. A tracer dose of ^{32}P given 2, 4 or 8 hr. before the rats or guineapigs were killed showed that the rate of cell proliferation was much greater in the intestine of the rat than of the guineapig.

WILLIAMS, W. L., STIFFEY, A. V. and JUKES, T. H. **Microbiological and chick assay of vitamin B_{12} activity in feed supplements and other natural products.** *J. Agric. Food Chem.*, 1956, **4,** 364–367. [Nutrit. Physiol. Sect., Res. Div., Amer. Cyanamid Co., Pearl River, N.Y.]

A comparative study by 4 methods was made of the vitamin B_{12} potency of 40 samples of products obtained from bacterial or *Streptomyces* fermentations, sewage sludge, fish solubles or other sources of vitamin B_{12}. Recent modifications of the growth method with chicks and of microbiological methods with *Ochromonas malhamensis*, *Bacterium coli* and *Lactobacillus leichmannii* were used. Pseudocobalamins promoting growth of micro-organisms but not of animals were not present to any large extent in the materials tested. Some fermentation products contained substances which inhibited the growth of chicks. It was concluded that *L. leichmannii* gave a reliable result for most feed supplements but that an occasional biological or protozoan test was advisable.—A. M. Copping.

DE MERRE, L. J. and WILSON, C. **Photolysis of vitamin B_{12}.** *J. Amer. Pharm. Assoc.*, 1956, **45,** 129–134. [Med. Labs., Army Chem. Centre, Md.]

Exposure for 2 hr. to sunlight of intensity about 8000 foot-candles caused 34 per cent. loss of potency of vitamin B_{12} in neutral solutions. There was no noticeable destruction after exposure to intensity of 300 foot-candles for the same length of time. Incandescent light of 14,000 foot-candles produced no detectable alteration. With monochromatic light destruction was found to be greater at the shorter wavelengths. A high light intensity in the red produced no destruction in 2 hr. Ultraviolet light showed a pattern similar to that of sunlight.—K. H. Coward.

DELLWEG, H., BECHER, E. and BERNHAUER, K. Biosynthesen in der Cobalamin-Reihe. 1. Cobalamin-Analoge der Benzimidazol-Reihe. [**Biosyntheses in the cobalamin series. 1. Cobalamin analogues of the benzimidazole series.**] *Biochem. Ztschr.*, 1956, **327,** 422–449. [Biochem. Forschungslab., Aschaffenburger Zellstoffw., Stockstadt a.M.]

1. With "etiocobalamin" obtained as described by Friedrich and Bernhauer (*Angew. Chem.*, 1953, **65,** 627) as starting material, resting cells of a wild strain of *Bacterium coli* synthesised benzimidazole analogues of cobalamin from 5 : 6-dimethyl-5-methyl-, 5 : 6-diethyl-, and 5 : 6-dichloro-benzimidazole. Many other substituted benzimidazoles were tested but few cobalamin analogues were obtained. It appeared that substitution in the C_2 position in the benzimidazole molecule by methyl, phenyl, amino or hydroxy groups prevented biological synthesis of a cobalamin analogue. Certain other C_2 substituents such as carboxyl, acid amide or hydroxymethyl groups could be eliminated by the organism, and benzimidazole analogues then formed. The analogues were identified by spectroscopic and chromatographic procedures and their biological activity was measured with *Ochromonas malhamensis*, *Bact. coli* 113–3 and *Lactobacillus leichmannii* 313.—A. M. Copping.

4451

FANTES, K. H., O'CALLAGHAN, C. H. and GOODINSON, D. W. **A note on the comparison of the microbiological potencies of two different growth factors with special reference to the assay of desdimethylcyanocobalamin.** *Biochim. biophys. Acta*, 1956, **20,** 397–398. [Glaxo Laboratories, Ltd., Sefton Park, Stoke Poges, Bucks.]

In tests with *Bacterium coli*, desdimethylcyanocobalamin appeared to be about 2·4 times as potent as cyanocobalamin under carefully defined conditions. Studies of the responses showed some difficulties inherent in the making of such comparisons.—A. M. Copping.

4452

BAURIEDEL, W. R., PICKEN, J. C. (Jr.) and UNDERKOFLER, L. A. **Reactions of cyanocobalamin and aquocobalamin with proteins.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 377–381. [Vet. Med. Res. Inst., Ames, Iowa.]

For investigating the reactions between cobalamins and proteins, a method was devised which depended on the different rates of dialysis in a special apparatus of free and combined cyanocobalamin and aquocobalamin. By using cobalamins labelled with ^{60}Co, the free and combined forms could be measured directly. Aquocobalamin (vitamin B_{12b}) appeared to combine more readily than vitamin B_{12} with diverse protein preparations. Denaturation increased and an acid medium decreased the affinity between protein and vitamin, and it is suggested that formation of cobalichrome might play a part in the reactions. Cyanocobalamin and aquocobalamin were bound equally by extracts of gastric mucosa, and the formation of complexes was not affected by excess of cyanide in neutral solution but was inhibited by it in highly alkaline media. The relation between formation of complexes with proteins and the structure of vitamin B_{12} is discussed.

PLUM, C. M. **Effects of liver extracts and vitamin B_{12} on experimentally produced liverfibrosis with macrocytosis compared with the effect of a spleen extract.** *Arch. internat. Pharmacodyn.*, 1956, **105,** 49–67. [Lab. Colony Filadelfia, Dianalund, Denmark.]

Fibrosis of the liver associated with macrocytosis was produced in male rats by ligation of the common bile duct. An earlier observation that spleen extract partly protected against those changes was confirmed. Crude liver extract given parenterally gave a similar degree of protection, but purified liver extracts and vitamin B_{12} were ineffective.—L. Wills.

4454

WONG, W. T. and SCHWEIGERT, B. S. **Role of vitamin B_{12} in nucleic acid metabolism. 1. Hemoglobin and liver nucleic acid levels in the rat.** *J. Nutrition*, 1956, **58,** 231–242. [Div. Biochem. Nutrit., Amer. Meat Inst. Found., Chicago, Ill.]

When deficiency of vitamin B_{12} was induced in rats by giving a diet containing iodinated casein, growth rate and ability to regenerate liver tissue after partial removal of the liver were less than in animals given vitamin B_{12}; the deoxyribonucleic acid and ribonucleic acid contents of the liver were low also.

Deficiency of vitamin B_{12} uncomplicated by the effect of iodinated casein on the thyroid gland was produced in young rats born of mothers deprived of vitamin B_{12} on a diet in which protein was from soya bean. In the young animals the growth rate and ribonucleic acid content of the liver were significantly low; 4 or 10 per cent. of dried liver added to the diet did not improve the growth response to vitamin B_{12} though it raised the Hb content of the blood, which was low in rats not given vitamin B_{12}. The young rats on the soya protein diet had scaly feet and porphyrin-stained whiskers.—A. M. Copping.

4455

ERICSON, L. E., HARPER, A. E., WILLIAMS, J. N. (Jr.) and ELVEHJEM, C. A. **Effect of diet on the betaine-homocysteine transmethylase activity of rat liver. 2. Vitamin B_{12}.** *J. Biol. Chem.*, 1956, **219,** 59–67. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Transmethylase activity in the betaine-homocysteine system was measured in homogenates of rat liver and expressed as μg. methionine per g. fresh liver as described by Ericson and Harper (Abst. 4505, Vol. 26). Vitamin B_{12} was estimated with *Lactobacillus leichmannii*. Iodinated casein was not used to produce vitamin B_{12} deficiency, since in preliminary experiments it was found to reduce liver transmethylase whether vitamin B_{12} was present or not. In rats receiving purified diets with or without vitamin B_{12} for 10 weeks, differences in growth rate were slight, but the transmethylase and vitamin B_{12} contents of the liver were less in rats deprived of the vitamin. Liver transmethylase activity was not affected by addition *in vitro* of the apoenzyme (Ericson *et al.*, *J. Biol. Chem.*, 1955, **212,** 537), but with livers from rats deprived of vitamin B_{12} addition of the cofactor raised the transmethylase activity to that of livers from animals given vitamin B_{12}. Vitamin B_{12} added to the liver preparations increased also the synthesis of labile methyl groups. Adenine triphosphate and α-ketoglutarate were found to be essential for the full effect of vitamin B_{12} *in vitro*. The findings are discussed with reference to other recent studies of the role of vitamin B_{12} in transmethylation. It is concluded that in the rat vitamin B_{12} influences the synthesis of methionine through its effects on the formation of the cofactor of betaine-homocysteine transmethylase and on new synthesis of labile methyl groups.

SREENIVASA MURTHY, V., DESIKACHAR, H. S. R. and SWAMINATHAN, M. **Effect of vitamin B_{12} deficiency on liver dehydrogenase activity in rats.** *Nature*, 1956, **177,** 750–751. [Central Food Technol. Res. Inst., Mysore.]

In the liver of young rats born of mothers deprived of vitamin B_{12} and maintained for 12 weeks on a basal diet without the vitamin, the activity of lactic, glutamic, succinic, butyric and choline dehydrogenase was reduced. Addition of

vitamin B_{12} to liver homogenates *in vitro* did not raise the dehydrogenase activities to equal those of normal livers.—A. M. Copping.

4457

MARTINI, V. Richerche sulla rigenerazione delle fibre nervose corneali : azione della vitamina B_{12}. [**Regeneration of the corneal nerve fibres: action of vitamin B_{12}.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31,** 745–746. [Ist. Fisiol., Univ. Bari.]

In rabbits weighing about 2 kg., fed on a mixed diet, the corneal nerves were cut under general anaesthesia. Some rabbits were given a daily intravenous injection of 30 μg. vitamin B_{12}. Regeneration of the corneal nerve was judged by return of the blinking reflex. The mean time in days for the return of the reflex was 22·2 for 14 eyes of rabbits given vitamin B_{12}, and 30·7 for 26 eyes of untreated rabbits.—E. M. Hume.

4458

WEIS, J. Sur l'absorption de la vitamine B_{12} radioactive par l'intestin isolé du rat. [**Absorption of radio-active vitamin B_{12} by the isolated intestine of the rat.**] *C.R. Acad. Sci.*, 1956, **242,** 2598–2600.

Isolated segments of rat intestine were incubated for 2 hr. in Warburg flasks in Krebs medium with known amounts of vitamin B_{12} containing ^{60}Co; they were then thoroughly washed with fresh medium, and the retention of vitamin B_{12} was measured from the radio-activity of the tissue. It appeared that the vitamin was rapidly absorbed by the intestinal mucosa and, once fixed, was not removed by washing. The amount absorbed depended on the original concentration of vitamin B_{12} in the medium.—A. M. Copping.

4459

HOLDSWORTH, E. S. and COATES, M. E. **Absorption of vitamin B_{12} from the rat intestine.** *Nature*, 1956, **177,** 701–702. [Nat. Inst. Res. Dairying, Univ. Reading.]

Absorption of vitamin B_{12} containing ^{57}Co, alone, or with saline extract of rat's stomach, or a crude intrinsic factor from pig's pyloric mucosa, or a purified protein isolated from the crude preparation, was studied in rats by a technique involving isolation *in vivo* of a section of the small intestine. The extract of rat's stomach increased absorption but intrinsic factor from pig's stomach had a slight inhibitory effect. With all preparations vitamin B_{12} was shown to be bound to protein, but it appeared that only homologous bound forms from the same species were available to the rat.

A. M. Copping.

4460

NIEWEG, H. O., ARENDS, A., MANDEMA, E. and CASTLE, W. B. **Enhanced absorption of vitamin B_{12} in gastrectomized rat by rat intrinsic factor.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 328–332. [Thorndike Mem. Lab., City Hosp., Boston, Mass.]

Excretion in the faeces of radio-active vitamin B_{12} containing ^{60}Co after a single dose of 0·015 μg. was measured in normal and gastrectomised rats. Normal rats absorbed 40 to 60 per cent. of the vitamin B_{12} but gastrectomised rats excreted almost the entire dose. When a preparation of intrinsic factor from rat's stomach was given with the radio-active vitamin to gastrectomised rats, absorption of vitamin B_{12} was normal. Intrinsic factor as human gastric juice or a preparation of pig's stomach had no effect. The intrinsic factor in rat's stomach thus appeared to be specific for that animal.—A. M. Copping.

4461

MILLER, R. F., NORRIS, L. C. and HEUSER, G. F. **The vitamin B_{12} requirement of White Leghorn chicks.** *Poultry Sci.*, 1956, **35,** 342–349. [Agric. Exp. Stat., Cornell Univ., Ithaca, N.Y.]

When breeding hens were given 0·125 or 0·19 μg. vitamin B_{12} per 100 g. diet, 63 and 83 per cent., respectively, of the eggs hatched. Vitamin B_{12} was estimated in the liver and unabsorbed yolk sac of the chicks at hatching. and a reasonably good correlation was found to exist between the amounts of vitamin B_{12} in the yolks of the hens' eggs, the livers and unabsorbed yolk sacs of the chicks and the hatching capacity of the fertile eggs. The requirement of the chick during the first 6 weeks of life was related to these values. When about 63 per cent. of the eggs hatched the chick's requirement for vitamin B_{12} was not more than 0·25 μg. per 100 g. diet or 0·53 μg. per 100 g. liveweight gain ; when 83 per cent. hatched the chick's requirement was not more than 0·125 μg. per 100 g. of a diet estimated to provide 194 Cal. productive energy, or 0·16 μg. per 100 g. of a diet that provided from 234 to 242 Cal. The requirement of these chicks per 100 g. gain was not more than 0·37 μg. The addition of pantothenic acid to practical rations, which usually contain 1 mg. free pantothenic acid per 100 g., did not decrease the chick's vitamin B_{12} requirement.

E. M. Cruickshank.

4462

KUROKI, M., YAMAGUCHI, M. and IWAMURA, I. **Observation and discussion on the effect of vitamin B_{12}-administration in goats on the secretion of milk.** *Bull. Fac. Agric. Univ. Miyazaki*, 1956, **1,** 171–175. [Lab. Zootech. Sci., Fac. Agric., Univ. Miyazaki.] In Japanese : English summary.

Vitamin B_{12}, 0·05 μg. per kg. bodyweight daily for 10 days, given by intramuscular injection,

increased the yield of milk, butterfat and casein of an Alpine goat weighing 38·1 kg. A larger amount, 0·12 μg., gave only a slight improvement in a goat weighing 45·4 kg. compared with a third goat without extra vitamin. The results suggested that a definite amount of vitamin B_{12} was necessary for the synthesis of milk constituents by goats given a standard ration of concentrates and roughage. (From summary.)—T. D. Bell.

4463

NURMIKKO, V. and VIRTANEN, A. I. Der Vitamin-B_{12}-(Cobalamin-) Gehalt der Kuhmilch. [**Vitamin B_{12} (cobalamin) content of cow's milk.**] *Milchwissenschaft*, 1956, **11**, 192–196. [Lab. Valio, Biochem. Inst., Helsinki.] English, Spanish and French summaries.

The average vitamin B_{12} content of milk from 8 farms, estimated microbiologically with *Euglena gracilis*, was 3·9 μg. per litre; for morning and evening milk the average values were 3·8 and 4·0. Large differences were found between individual cows, and at different stages of lactation in the same cow, with a range from 1·3 to 14·5 μg. per litre for single samples of milk. In general a high milk yield was associated with a low value for vitamin B_{12} and a low yield with a high value. There was little difference in the vitamin B_{12} content of their milk between cows on pasture and stall-fed cows except on one farm where inclusion in the feed of large amounts of A.I.V. silage was associated with a high vitamin B_{12} content.

VITAMIN C (ASCORBIC ACID)

4464

MOOR, H. Bestimmung der Ascorbinsäure in Lebensmitteln und biologischem Material. [**Estimation of ascorbic acid in foods and biological material.**] *Mitt. Geb. Lebensmittel. Hyg.*, 1956, **47**, 20–27. [Lab. Vit. Abt., Hoffmann la Roche Co. A.G., Basle.] French and English summaries.

In an improved form of the method of Schmall and colleagues (Absts. 1852, Vol. 24; 2034, Vol. 25), diazotised 2-nitroaniline was used instead of 4-methoxy-2-nitroaniline; the yellow product of reaction with ascorbic acid was extracted from the aqueous solution with *iso*butanol, the reddish blue sodium salt was formed and removed by shaking with 2 per cent. (w/v) NaOH, and the extinction at 540 mμ. was compared with that of a blank in which any ascorbic acid present had been oxidised with dichlorophenolindophenol. For concentrations between 0·5 and 4 μg. ascorbic acid per ml. the relation between concentration and extinction was linear. Recovery of ascorbic acid added to difficult materials, such as roasted coffee, dried skimmed milk, red wine, flour and a vitamin tonic, was much better than by Schmall's method or by titration with dichlorophenolindophenol; the error did not exceed 10 per cent. The application of the method to dried whole milk is described in detail.

W. M. Deans.

OWEN, J. A. and IGGO, B. **The use of *p*-chloromercuribenzoic acid in the determination of ascorbic acid with 2 : 6-dichloro-phenolindophenol.** *Biochem. J.*, 1956, **62**, 675–680. [Dept. Clin. Chem., Univ. Edinburgh.]

Spontaneous fading of indophenol at *p*H below 3·5 made colorimetric estimation based on the reduction of indophenol impossible at such *p*H. *p*-Chloromercuribenzoic acid did not affect the reduction of indophenol by ascorbic acid (see Abst. 2035, Vol. 25) but suppressed almost completely the reducing activity of many S compounds, with the exception of sulphite. It removed almost completely the interfering reducing substances in extracts of human erythrocytes and of rat liver and kidney, but those in human urine only partly. It was concluded that use of *p*-chloromercuribenzoic acid increased the specificity of the indophenol method for estimating ascorbic acid in biological material.—A. Hepburn.

TORII, K. and MORIYAMA, T. **On the interaction of cyclic amino acids with ascorbic acid. 1. 2.** *J. Biochem., Tokyo*, 1955, **42**, 193–199; 201–206. [Dept. Biochem., Med. Univ., Nara.]

1. Low values had been obtained in estimations of tryptophan. Spectral absorption curves showed that when ascorbic acid was present interaction occurred between it and tryptophan, resulting in tryptophan values 30 per cent. below those expected theoretically. The finding was confirmed by paper chromatography, and further experiments suggested that the reaction took place in the nucleus, not in the side chain. A kynurenine-like substance was formed when air bubbled through a mixture of tryptophan and ascorbic acid at 37° C.

Ascorbic acid interfered with the estimation of tyrosine and histidine also.

2. For the formation of kynurenine when air was bubbled through a mixture of tryptophan and ascorbic acid the optimum *p*H was 5·2, and Cu^{++} but not Fe^{+++} catalysed the reaction. Colloidal platinum decreased the production of kynurenine

by 70 per cent. and the effect was not influenced by the addition of cyanide.

It is concluded that tryptophan combines loosely with ascorbic acid and that hydrogen peroxide is then formed and acts upon the complex to promote decomposition to kynurenine.

Comportamento cromatografico. [**6. Chromatographic behaviour.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31,** 826–827; 827–828. [Ist. Biochim., Univ. Messina.]

5. Combined vitamin C was estimated by difference after hydrolysis, by a method previously described (Abst. 2157, Vol. 22), in samples of pulp taken from the same 4 lemons left hanging on the tree, at 9.0 a.m. and 5.0 p.m. on 6 successive days. The mean values for combined vitamin C were always higher in the morning and decreased with maturation; the morning and evening values, respectively, in mg. per 100 g. pulp, were 13·09 and 5·46 on the second day and 7·51 and 2·16 on the sixth day.

6. The protein precipitate from the juice of citrus fruits was washed till it no longer gave any reaction for vitamin C. After acid hydrolysis of the precipitate, free vitamin C was recognised by paper chromatography and comparison with an authentic sample of ascorbic acid. (See also Abst. 2157, Vol. 22.)—E. M. Hume.

ZWEEDE, A. K. De voedingswaarde van zwarte bessen. [**Nutritive value of black currants.**] *Voeding*, 1956, **17,** 125–132. [Inst. Bewaring Tuinbouwprod., Wageningen.] English summary.

Published values for the vitamin C content of black currants are discussed with special reference to varieties and crosses. New results from Wageningen are reported for vitamin C, sugar, acid and dry matter in 12 varieties which contained from 202 to 246 mg. vitamin C per 100 ml. juice and 8 varieties with only from 72 to 104 mg. There was no obvious difference in the other components measured.—I. Leitch.

4471

KERSTEN, H., KERSTEN, W. and STAUDINGER, H. Zum Wirkungsmechanismus der Ascorbinsäure. [**Mode of action of ascorbic acid.**] *Biochem. Ztschr.*, 1956, **328,** 24–34. [Zentrallab., Städt. Krankensanst., Mannheim.]

Further experiments on the effect of ascorbic acid in accelerating the removal of hydrogen from dihydrodiphosphopyridine nucleotide by adrenal mitochondria and on the influence of ultraviolet light confirmed earlier results (Absts. 485, 1810, Vol. 26). As before, dehydroascorbic acid was inactive; D-*iso*ascorbic acid was about 1/5 as active as L-ascorbic acid.

When dihydrodiphosphopyridine nucleotide and adrenal mitochondria were allowed to react in a Warburg apparatus, consumption of oxygen was greatly increased by addition of ascorbic acid, which was taken as further evidence in favour of the authors' hypothesis that the effect of ascorbic acid on biosynthesis of corticosteroids in the adrenal cortex is to be ascribed to activation of cell respiration.

The exact mode of action of ascorbic acid remained unclear; reasons are given against the idea that it might be due to intermediate formation of peroxide and the suggestion of an active radical, perhaps monodehydroascorbic acid, is repeated.

Preparations of mitochondria from pig adrenals themselves contained 26 mg. ascorbic acid per 100 g. dry weight even after 3 washings, which is about 1 per cent. of the total adrenal ascorbic acid.

EHMKE, D. A., DAVEY, B. L. and TODHUNTER, E. N. **The influence of age and diet on ascorbic acid metabolism in rats.** *J. Nutrition*, 1956, **58,** 281–290. [Lab. Human Nutrit., Sch. Home Econ., Univ. Alabama, Tuscaloosa.]

Three groups of weanling male and female rats were fed on a stock diet, or the same diet with addition of 50 mg. ascorbic acid daily for 21 days before being killed or a synthetic diet free of ascorbic acid for the last 21 days. The rats were killed at 63 or 112 days of age. In all groups males had a significantly higher value for ascorbic acid in plasma, whole blood, and white cell and platelet fractions than females. There was no difference

between groups of the same sex, and with one exception age had no significant effect. With the supplement of ascorbic acid there was increased excretion of the vitamin in the urine, but the increase was small compared with the amount given ; relative to bodyweight there was no difference between the sexes in the amount excreted. Males had significantly heavier livers and kidneys and lighter adrenal glands than females, but the ascorbic acid concentrations were significantly different only in the kidneys, being greater in males. The supplement of ascorbic acid increased the ascorbic acid content of the liver in males at 63 days of age, but the content in the adrenal glands, kidneys and sex organs was not affected by the supplement or by age.—A. Hepburn.

McCraw, J. Y. Mécanisme d'action de l'acide ascorbique sur les temps de saignement et de coagulation. [**Mode of action of ascorbic acid on bleeding and coagulation times.**] *Rev. canad. Biol.*, 1956, **14,** 295–321. [Dept. Exp. Physiol., Laval Univ., Quebec.] English summary.

In guineapigs rendered fully scorbutic, compared with normal animals, there was an increase of 50 per cent. in prothrombin time, a decrease of 45 per cent. in the number of platelets and an increase of 60 per cent. in fibrinogen which was probably associated with the scorbutic haemorrhages ; serum Ca concentration was not appreciably altered. A decrease in antithrombin was considered probable as the serum albumin with which it is associated was reduced. The results and the literature on the factors affecting bleeding time and coagulation, with special reference to the changes seen in scurvy, are discussed in considerable detail.—L. Wills.

McCraw, J. Y. and Desmarais, A. Influence des vitamines A et D sur le temps de saignement et de coagulation chez le cobaye carencé ou non en acide ascorbique. [**Effect of vitamins A and D on bleeding and coagulation time in the normal or vitamin C deficient guineapig.**] *C.R. Soc. Biol.*, 1955, **149,** 2060–2063. [Dept. Exp. Physiol., Laval Univ., Quebec.]

Four groups of 15 guineapigs were given a diet without vitamin C for 56 days. Daily supplements were given to groups 2 and 4 of 5·0 mg. ascorbic acid, and to groups 3 and 4 of 0·075 mg. calciferol for the first 16 days and of 0·075 mg. β-carotene during the rest of the period. Group 1 was without supplement. At intervals bleeding time and coagulated time were measured.

Without ascorbic acid or other supplement bleeding time had risen by 37·9 per cent. in the 56 days. With ascorbic acid alone bleeding time fell by 20·5 per cent. in 16 days, but the fall did not persist, and the initial value was regained at the end of the 56 days. Vitamin D did not affect the bleeding time of animals without ascorbic acid but prevented the fall in those given it. When carotene was substituted for it there was a fall followed by a rise in those given and not given ascorbic acid.

Coagulation time rose steadily in the deprived animals without supplement, and at the end of the experiment was 62·1 per cent. greater than at the beginning. With ascorbic acid the coagulation time had fallen by 10·9 per cent. at the end of the experiment. Vitamin D had no appreciable effect, but in the animals without ascorbic acid carotene gave a slight rise of 6·1 per cent. by the 56th day.—I. M. Sharman.

Desmarais, A. and McCraw, J. Y. Étude de la crase sanguine chez le cobaye carencé ou non en acide ascorbique. [**Blood picture of guineapigs deprived and not deprived of ascorbic acid.**] *Rev. canad. Biol.*, 1956, **14,** 322–329. [Dept. Exp. Physiol., Laval Univ., Quebec.] English summary.

In adult guineapigs given a scorbutogenic diet, hypochromic anaemia appeared associated with a decrease of platelets and an increase of leucocytes, due in the early stages of the deficiency to an increase of granulocytes and later to an increase of lymphocytes. Animals having the same diet with ascorbic acid had a normal blood picture.

Sakai, N. and Shimosato, E. **On the influence of the deficiency of ascorbic acid upon the activity of the complement in the serum.** *J. Biochem., Tokyo*, 1955, **42,** 677–684. [Biochem. Inst., Matsumoto Med. Coll.]

Complement was estimated from the degree of haemolysis produced in sheep's red cells by the serum containing the complement in presence of haemolysin. Ascorbic acid was estimated in serum by the method with 2 : 4-dinitrophenylhydrazine. Guineapigs were given a scorbutogenic diet and, by injection, 50 mg. ascorbic acid daily for about a week. One group was then continued in the same way, and the other was given no further ascorbic acid. Even when signs of scurvy were present and the concentration of ascorbic acid in the serum was low, there was no effect on the activity of complement. *In vitro* the activity of the complement in guineapig serum was not affected by adding ascorbic acid to the serum or by destroying the ascorbic acid in the serum with $CuCl_2$.—E. M. Hume.

4477

LAHIRI, S. and BANERJEE, S. **Coenzyme A activity in tissues of normal and scorbutic guinea pigs.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 583–584. [Dept. Physiol., Presidency Coll., Calcutta.]

Scorbutic guineapigs excreted in the urine less injected *p*-aminobenzoic acid in the acetylated form than normal guineapigs (see earlier work, Abst. 539, Vol. 25). Coenzyme A activity in the liver, kidneys, and brain was unchanged. Total body cholesterol rose. It is suggested that oxidation of acetate by way of the tricarboxylic acid cycle is inhibited in scurvy and that excess acetate might be used to increase synthesis of cholesterol.

FABIANEK, J. Influence du taux de caséine et de l'amide de l'acide nicotinique sur la croissance, la résistance vasculaire et les taux tissulaires d'acide ascorbique du cobaye. [**Effect of the amount of casein and nicotinamide on growth, vascular resistance and concentration of ascorbic acid in the tissues of the guineapig.**] *C.R. Soc. Biol.*, 1956, **150,** 88–92.

Guineapigs of about 300 g. weight given 20 mg. ascorbic acid daily and a purified diet containing 30 per cent. casein showed no significant difference in growth rate, capillary resistance or ascorbic acid content of the liver, kidney, spleen, adrenal glands and blood whether nicotinamide was included or not. When the casein content of the diets was reduced to 14 per cent., growth and capillary resistance were not affected but ascorbic acid in the organs was higher especially in the spleen and adrenal glands, whether nicotinamide was given or not.—A. M. Copping.

4479

LAHIRI, S. and BANERJEE, S. **Metabolic interrelationship between ascorbic acid and pteroylglutamic acid.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 545–548. [Dept. Physiol., Presidency Coll., Calcutta.]

Groups of 12 rats weighing from 100 to 170 g. were given a diet of milk and added minerals. With a supplement of 40 μg. aminopterin daily they excreted less ascorbic acid in the urine than rats on the diet alone, but rats given 20 mg. chloretone daily excreted much more ascorbic acid than untreated rats even when given aminopterin or sulphaguanidine as well. Aminopterin reduced the concentration of ascorbic acid in the liver, kidneys, adrenal glands and intestine; chloretone increased it, except in the adrenal glands of normal rats. Chloretone or aminopterin alone or together had no effect on the concentration of ascorbic acid in the testis and pancreas. Chloretone also increased further the amount of citrovorum factor in the urine of rats with an excretion already high through administration of pteroylglutamic acid, and raised the concentration of ascorbic acid but not of citrovorum factor in the liver.—A. Hepburn.

4480

DEBONS, A. F., WALLACE, J. W. and BACCHUS, H. **Ketone body metabolism in ascorbic acid deficiency. *In vitro* formation of ketone bodies by liver slices.** *Amer. J. Physiol.*, 1956, **185,** 31–34. [Dept. Physiol., Sch. Med., George Washington Univ., Washington, D.C.]

When incubated with phosphate buffer, liver slices from scorbutic guineapigs produced less ketone bodies than slices from pair-fed animals given ascorbic acid, which produced more than slices from normal guineapigs. When octanoate was added to the medium, ketone production by liver slices from scorbutic guineapigs was significantly greater than in the other groups over a whole period of 31 days, but daily analyses revealed no significant difference. The fat content of the liver of scorbutic guineapigs was normal, but the results suggested that the decreased formation of ketones might be related to a decrease in the availability of fatty acids from liver fat.—A. Hepburn.

DAYTON, P. G., REICHENTHAL, J. and BURNS, J. J. **Observations on bound ascorbic acid in guinea pig liver.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 326–327. [Third (N.Y. Univ.) Med. Div., Goldwater Mem. Hosp., New York.]

The average percentage of bound ascorbic acid (see Absts. 2098, 2102, Vol. 22) in the liver from 3 guineapigs, calculated from measurements of radio-activity 24 hr. after injection of L-ascorbic-1-^{14}C acid, was 19 and in 2 guineapigs given a diet without ascorbic acid for 14 days, 28. When D-ascorbic-1-^{14}C acid was injected into 2 guineapigs fed on the scorbutogenic diet, the percentage in the liver that was bound was about 35, 2 hr. after the injection.—A. Hepburn.

4482

LANGHAM, M. E. and HEALD, K. **Factors affecting the concentration of ascorbic acid in the crystalline lens of cattle and rabbits.** *Biochem. J.*, 1956, **63,** 52–56. [Ophthalmol. Res. Unit (Med. Res. Counc.), Inst. Ophthalmol., London, W.C.1.]

In 14 rabbits the concentration of ascorbic acid in the lens was about 80 per cent. of that in the aqueous humour. The average values were 18·9 and 24·4 mg. per 100 g. water with ranges of 11 to 37 and 13 to 40. The average amount of dehydroascorbic acid and diketogulonic acid together in the lens was 3·6 mg. There was no difference between

right and left eyes, and the concentration did not change 2 hr. after death. Intramuscular injection after a single intravenous injection of ascorbic acid raised the concentration in both the aqueous humour and lens, but much less in the lens. Whole rabbit and cattle lenses inhibited the destruction of ascorbic acid in ox aqueous humour diluted with phosphate buffer; dehydroascorbic acid increased the effect. Dehydroascorbic acid in phosphate buffer was reduced by dialysed extracts of cattle or rabbit lens in the presence of reduced glutathione, but the process was apparently not enzymic. It is concluded that the concentration of ascorbic acid in the lens is governed mainly by the rate of transfer of ascorbic acid into the eye and the permeability of the lens to ascorbic acid.

A. Hepburn.

4483

BÁRÁNY, E. and LANGHAM, M. E. **On the origin of the ascorbic acid in the aqueous humour of guinea-pigs and rabbits.** *Acta physiol. scand.*, 1955, **34**, 99–115. [Pharmacol. Inst., Univ. Upsala.]

Ascorbic acid was estimated by the method of Roe and Kuether (Abst. 261, Vol. 13).

As the ascorbic acid in the plasma of guineapigs fed on a scorbutogenic diet approached zero that in the aqueous humour disappeared, but in rabbits the value in the aqueous humour was 14 mg. per 100 ml. when the value in the plasma was at its lowest. The transport mechanism of the ciliary processes was saturated when the value in the plasma was about 0·8 mg. per 100 ml. for guineapigs and from 2 to 3 mg. per 100 ml. for rabbits. Above those plasma values there were steady concentrations of 24·6 and 67·5 mg. per 100 ml. in the aqueous humour. Repeated injection of dehydroascorbic acid did not raise the concentration of ascorbic acid above that corresponding to the concentration in the plasma. High concentrations of dehydroascorbic acid or its degradation products appeared to depress the transfer mechanism in guineapigs. It was concluded that the uptake of dehydroascorbic acid from the plasma by the ciliary processes was of little importance for the maintenance of ascorbic acid concentration in the eye, and that although local synthesis of ascorbic acid might occur in rabbits it did not occur in guineapigs.—A. Hepburn.

UYAMA, Y., OGINO, S. and ICHIHARA, T. **Biochemical studies on cataract. 3. Experimental black cataract and ascorbic acid.** *Med. J. Osaka Univ.*, 1955, **6**, 761–766. [Dept. Ophthalmol., Med. Sch., Osaka Univ.]

For part 2 see Abst. 3095, Vol. 26.

3. When a daily intraperitoneal injection of 30 mg. dihydroxyphenylalanine (dopa) quinone was given to 2 guineapigs fed on a scorbutogenic diet, cataracts appeared after 3 or 4 days. With other pairs of animals treated in the same way but given 0·05 and 0·2 mg. ascorbic acid daily, cataracts developed after 5 and 7 days and with the latter dose they were black. Of 2 guineapigs given dopa quinone and 2 mg. ascorbic acid, one survived for over 25 days and the other died after 13 days. Cataracts did not develop.

Ascorbic acid apparently prevented the formation of cataracts by virtue of its reducing properties. When anthranilic acid with a similar redox potential replaced ascorbic acid in doses of 0·5 and 1·0 mg. daily, cataracts developed after 4 or 5 and 7 or 8 days; with 1·0 mg. the cataracts were black. With 5 mg. there was no cararact. Glutathione and sodium thiosulphate in doses of 10 mg. daily did not prevent cataract.—A. Hepburn.

4485

UYAMA, Y. and OGINO, S. **Studies on the metabolism of vitamin C in the crystalline lens. 4. Distribution of diketogulonic acid in the crystalline lens.** *Med. J. Osaka Univ.*, 1955, **6**, 767–770. [Dept. Ophthalmol., Med. Sch., Osaka Univ.]

For part 3 see Abst. 3094, Vol. 26.

4. In 30 fresh eyes from rabbits the average concentration of ascorbic acid, in mg. per 100 g. tissue, was in the lens 12·99, cornea 5·05, iris and ciliary body 7·88, choroid 5·98 and retina 8·88. Corresponding values for dehydroascorbic acid were 1·63, 0·67, 1·33, 1·06 and 1·46. Diketogulonic acid had a value of 1·15 in the lens but there was none in the other tissues. Separation into its parts of the rabbit, bovine and guineapig lens showed that all 3 acids were present in the cortex, ascorbic acid in the greatest amount. Dehydroascorbic acid was present in the capsule, cortex and nueleus, but there was a negligible amount of ascorbic acid and no diketogulonic acid in the capsule and nucleus.—A. Hepburn.

4486

ABERCROMBIE, M., FLINT, M. H. and JAMES, D. W. **Wound contraction in relation to collagen formation in scorbutic guinea-pigs.** *J. Embryol. Exp. Morphol.*, 1956, **4**, 167–175. [Dept. Anat., University Coll., London.]

After tattoo marks enclosing 2 squares of average area 25·5 sq. mm. had been made, one on each side of the dorsilumbar region, guineapigs were given a scorbutogenic diet with or without ascorbic acid. After 5 days tracings were taken of the tattoo points and within one set a square wound of 17 sq. mm. was made. Ten days later the animals were killed and tracings were again taken. Collagen in newly formed tissue and in scabs was estimated by the method of Neuman and Logan (Title 4638,

Vol. 20) based on estimation of the hydroxyproline content.

Repair tissue was similar in amount in the 2 groups; mean wet weights were 13·0 ± 1·7 mg. in the deprived and 10·3 ± 1·3 mg. in the non-deprived group. There were differences in texture and hydroxyproline content; in the deprived group the texture was friable and the hydroxyproline content was, on the average, 10·4 ± 2·6 μg., but in the non-deprived group the texture was firm and the content 74 ± 8 μg. Scabs were smaller in area and thinner in the non-deprived than in the deprived group; their mean wet weights were 3·7 ± 1·4 and 28 ± 6 mg., respectively. In the deprived group the content of hydroxyproline in the scabs was 112 ± 23 μg. and was substantially greater than in the non-deprived group, when it was 10 ± 8 μg.

The average contraction during 10 days was 8·3 ± 1·0 sq. mm. in the deprived animals and 10·1 ± 1·4 sq. mm. in the non-deprived. The extent was significant in the deprived group and did not differ significantly from that in the non-deprived group.

There was no evidence from the non-wounded squares in the groups that lack of ascorbic acid caused loss of collagen from the tissue.

It is suggested that the force causing contraction is produced not by newly formed collagen but by the connective tissue cells within the wound.

RUDAS, B. (with NAGY, G.) **Changes in the nucleoprotein content of granulation tissue on the effect of vitamin C in various modes of administration.** *Acta physiol. hung.*, 1955, **8,** 253–258. [Nat. Inst. Food Nutrit. Sci., Budapest.] Russian summary.

Four groups of guineapigs were fed on a normal diet, a scorbutogenic diet, or a scorbutogenic diet containing 10 mg. ascorbic acid as a vegetable or as the synthetic vitamin. After 5 days the animals were wounded and from 17 to 24 days later they were killed. In the group having the scorbutogenic diet the amounts of ribonucleic acid and of deoxyribonucleic acid in epithelium-free granulation tissue from the wound were significantly less than in the other groups. When wounds in the group having had the scorbutogenic diet for 5 days were treated locally with ascorbic acid the amount of ribonucleic acid was less than normal, but if 1 mg. ascorbic acid was given daily by mouth for 5 days before wounding the nucleic acid values were normal. The daily administration of 50 mg. ascorbic acid by mouth or by injection at the time of wounding and subsequently [time not stated] failed to raise the ribonucleic acid value to normal.

JOHANNES, A., STAUDINGER, H. and WILZ, H. Stoffwechsel der Nebennierenrinde und Biosynthese der Corticosteroide. 10. Wirkung von ACTH auf den Ascorbinsäuregehalt von überlebendem Nebennierengewebe. [**Metabolism of the adrenal cortex and biosynthesis of cortical steroids. 10. Effect of ACTH on the ascorbic acid content of surviving adrenal tissue.**] *Biochem. Ztschr.*, 1956, **327,** 484–490. [Zentrallab., Städt. Krankenanst., Mannheim.]

Pituitary adrenocorticotropic hormone (ACTH) incubated with minced pig adrenal gland, 0·5 to 1·5 I.U. per g. tissue, raised the rate of formation of corticosteroids without change in the concentration of ascorbic acid.—I. Leitch.

4489

CONSTABLE, B. J., HARRIS, L. J. and HUGHES, R. E. **Effect of continued administration of cortisone and ACTH on vitamin C levels in guinea-pig adrenals.** *Brit. J. Nutrition*, 1956, **10,** 91–100. [Dunn Nutrit. Lab., Univ. Cambridge.]

Groups of 10 normal guineapigs were maintained for 20 days on diets containing graded amounts of ascorbic acid, from 0 to 50 mg. daily, or 15 g. cabbage daily. During the last 10 days half the animals received injections of 15 mg. cortisone acetate daily and some received 8 mg. adrenocorticotropic hormone. Some groups of 12 guineapigs received 7·5 mg. cortisone and ascorbic acid for 14 days.

Concentration of ascorbic acid in the adrenal glands rose with increase of ascorbic acid in the diet. The weight and ascorbic acid concentration in the glands decreased in the animals receiving cortisone. In those receiving adrenocorticotropic hormone the concentration fell but the total quantity rose since the glands were greatly enlarged. Nearly half of the changes were found individually significant by statistical analysis and the aggregate results were unlikely to be due to chance. The change in weight of the adrenal glands produced by cortisone or adrenocorticotropic hormone was independent of the dietary intake of ascorbic acid.

NATH, M. C. and NAYUDU, S. G. **Effect of acetoacetate on the adrenal cholesterol and ascorbic acid of guinea-pigs.** *Indian J. Med. Res.*, 1956, **44,** 289–294. [Dept. Biochem., Univ. Nagpur.]

When daily injections of acetoacetate, increasing from 175 mg. per kg. bodyweight by 40 mg. every 3 days for 21 days, were given to normal and scorbutic guineapigs, the concentration of cholesterol in the adrenal glands and blood was not affected.

Scorbutic guineapigs lost more ascorbic acid from the adrenal glands but the weight of the glands did not increase. All the animals given acetoacetate showed mild glycosuria and ketonuria. Normal guineapigs whose tissues were saturated with ascorbic acid showed no significant change in the concentration of cholesterol or ascorbic acid in the adrenal glands, 1½ or 3 hr. after a single injection of 300 mg. acetoacetate per kg. bodyweight, so that acetoacetate apparently did not exert its diabetogenic effect through stimulation of the adrenal cortex.—A. Hepburn.

4491

BLAMOUTIER, J. Effet de spoliations sanguines sur la teneur du cortex surrénalien en acide ascorbique. [**The effect of withdrawals of blood on the ascorbic acid content of the adrenal cortex.**] *C.R. Soc. Biol.*, 1956, **150,** 93 – 96. [Clin. Méd. Propédeutique, Hôp. Broussais, Paris 14.]

After withdrawal of 2 ml. blood from the ophthalmic sinus of rats the concentration of ascorbic acid in the adrenal glands fell by about 40 per cent. in 30 min. The decrease reached its maximum of about 53 per cent. after 3 hr., and the concentration returned to normal after 24 hr. In other experiments the extent of the decrease in ascorbic acid bore some relation to the amount of blood withdrawn.—A. Hepburn.

RATSIMAMANGA, A. R. and NIGEON-DUREUIL, M. Déviation du métabolisme des corticostéroïdes au cours du scorbut expérimental. [**Changes in metabolism of corticosteroids during experimental scurvy.**] *Bull. Soc. Chim. biol.*, 1956, **38,** 183–203. [Centre Nat. Recherche Sci., École Hautes-Études, Fac. Méd., Paris.] English and German summaries.

As scurvy developed in guineapigs the concentration of ascorbic acid and of water-soluble corticosteroids in the adrenal glands decreased. The concentration of total corticosteroids fluctuated, but the absolute total increased with the development of hypertrophy. The adrenal changes were not caused by absence of adrenocorticotropic hormone or inability of the adrenal glands to mobilise corticosteroids, since the glands remained sensitive to adrenocorticotropic hormone. Adrenal glands from scorbutic guineapigs, when incubated with progesterone or derivatives of cholesterol, synthesised less corticosteroids than normal glands, and metabolised deoxycorticosterone to polar compounds which were toxic to scorbutic animals. Ascorbic acid facilitated hydroxylation, oxidation and oxygenation of corticosteroids. It is suggested that the active cortical hormone may be a complex of corticosteroids, water-soluble vitamins including ascorbic acid, and perhaps forms of adrenocorticotropic hormone.—A. Hepburn.

MACDONALD, M. K. and BHATTACHARYA, S. K. **Histological changes in rats rendered hyperglycaemic by injection of dehydroascorbic acid.** *Quart. J. Exp. Physiol.*, 1956, **41,** 153–161. [Dept. Pathol., Univ. Edinburgh.]

The diabetogenic action of dehydroascorbic acid, which resembles alloxan in structure and properties, is well established.

Wistar Glaxo rats weighing from 145 to 216 g. were fed on cubes of a stock diet. Five fasting rats had injected from 0·7 to 0·8 ml. dehydroascorbic acid solution (100 mg. per ml.) per 100 g. bodyweight on 2 consecutive days and were killed 24 hr. later. A group of 9 rats was treated in the same way for 3 consecutive days and killed 4 days later. Six rats were given no dehydroascorbic acid. Blood sugar was estimated at least 24 hr. after the last injection and certain organs were taken for histological examination.

Blood sugar in 4 rats in the first group rose to between 252 and 316 mg. per 100 ml.; in the fifth it was only 92. Values for the 9 rats in the second group ranged from 336 to 500 mg. Values for those not given dehydroascorbic acid were from 89 to 124 mg. On histological examination, changes in the kidneys, liver and thyroid gland were not great; in the adrenal cortex there were changes in staining properties. In the pancreas of rats in the second group the number of islets was reduced; they were smaller and the structure was disorganised. The beta cells were fewer and smaller than normal; their cytoplasm was shrunken, and many nuclei were pyknotic. There was some deposition of glycogen in the cells. Alpha cells were not abnormal but varied greatly in number and distribution. In the first group of rats the changes were not nearly so severe. The changes were in many ways like those caused by alloxan.—E. M. Hume.

ENZYMES

4498

BERGAMINI, A., BENDANDI, A., MAGGI, G. and CHIEREGO, G. Azione di sostanze lipotrope sul quadro enzimatico del tessuto epatico nella steatosi da tetracloruro di carbonio. [**Effect of lipotropic substances on the enzymes of the liver made fatty by carbon tetrachloride.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31**, 800–801. [Ist. Clin. Med., Univ. Modena.]

Forty-one rats weighing from 130 to 150 g. were given intramuscular injections of CCl_4 for 15 days. They received in addition by intramuscular injection 100 mg. methionine, or 25 mg. choline chloride, or 60 mg. inositol, or by mouth 100 mg. lipotropic substance of the pancreas, or no addition. In the liver total lipids were increased by CCl_4. All the treatments decreased the toxic effect, choline and methionine having the greatest effect. Tributyrin esterase activity was reduced to about one-third; inositol did not counteract this effect, but the other supplements improved activity to nearly half the normal. Alkaline β-glycerophosphatase was increased somewhat by treatment with CCl_4; the activity was favourably affected by all the supplements, and was completely normal with choline and pancreatic factor. β-Glucuronidase activity was increased by about one-third by CCl_4 and was restored to normal by choline, methionine or pancreatic extract.—E. M. Hume.

KITTS, W. D., BAILEY, C. B. and WOOD, A. J. **The development of the digestive enzyme system of the pig during its pre-weaning phase of growth. A. Pancreatic amylase and lipase.**

BAILEY, C. B., KITTS, W. D. and WOOD, A. J. **B. Intestinal lactase, sucrase and maltase.**

Canad. J. Agric. Sci., 1956, **36,** 45–50 ; 51–58. [Div. Animal Sci., Univ. British Columbia, Vancouver.]

A. Pigs selected from 2 litters were killed at ages from birth to 49 days and the pancreas was removed and stored at — 10° C. Amylase and lipase activity were estimated in extracts.

Amylase activity relative to the weight of the pancreas and relative to bodyweight increased with age and bodyweight. The 5 estimations showed a large increase between 1 and 6 days of age and another between 22 and 37 days.

Lipase activity, estimated for 9 glands with fat from sow's milk, was high at birth and remained so without showing the same steady increase as amylase, although the activity on a bodyweight basis increased some 3½ times in 49 days.

B. Eleven and 10 pigs from 2 litters were killed at ages from birth to 51 days and the small intestine was washed out and stored at — 10° C. The intestine was divided into 3 sections before preparation of enzyme extracts.

At birth the extracts hydrolysed lactose, but not sucrose or maltose. Lactase activity was highest in pigs from 1 litter after 1 and 2 weeks and in the other litter after 3 weeks, and then declined sharply. Some sucrose and maltose were hydrolysed at 1 week and thereafter the amounts gradually increased until more sucrose and maltose than lactose were hydrolysed at 7 weeks. Activity of all 3 enzymes tended to be greatest in the middle third of the intestine.

MAGEE, D. F. and HONG, S. S. **Changes in pancreatic enzymes brought about by amino acid additions to the diet.** *Amer. J. Physiol.*, 1956, **184,** 449–452. [Dept. Pharmacol., Sch. Med., Univ. Washington, Seattle.]

In each of 2 experiments 40 rats in groups of 10 were given a semi-synthetic diet with 7 per cent. casein and, in the first, 1 per cent. *iso*leucine, methionine or phenylalanine or, in the second, leucine, lysine or tryptophan. In each experiment a control group had the diet with 8 per cent. casein and no added amino acid. Each animal was given 14 g. daily for 21 days. The rats were then killed and pancreatic enzymes were estimated by methods already described (Abst. 510, Vol. 26); amylase also was measured.

In the first experiment methionine increased both lipase and protease, phenylalanine and *iso*leucine only protease ; amylase was not significantly affected, but tended to be less in the phenylalanine and *iso*leucine groups than in the control group. In the second experiment the amino acids caused no change in any of the enzymes studied.—D. Harvey.

SZABOLCSI, G. and SZÖRÉNYI, E. **Action of trypsin and chymo-trypsin on native homologous proteins.** *Acta physiol. hung.*, 1956, **9,** 293–299. [Inst. Biochem., Hungarian Acad. Sci., Budapest.] Russian summary.

Crystalline bovine trypsin and chymotrypsin and non-crystalline horse and pig trypsin were prepared and were tested on purified human, bovine, pig and horse albumin and on crystalline 3-phospho-*d*-glyceraldehyde dehydrogenase (PGAD) from cattle, pig and rabbit.

Trypsin and chymotrypsin digested native protein very slowly. For example, bovine trypsin in 1 hr. digested bovine, horse and human albumins at relative rates of 100 : 170 : 250. Serum albumin from pigs was not digested at all by pig or bovine trypsin. For bovine trypsin the relative rates of digestion of PGAD from cattle, pig and rabbit were 100 : 145 : 260. The specific difference was not found with denatured proteins.—D. Duncan.

YOUNATHAN, E. S., FRIEDEN, E. and DITTMER, K. **Sensitivity of rat liver xanthine oxidase to amino acid analogues.** *J. Biol. Chem.*, 1956, **219,** 531–537. [Dept. Chem., Florida State Univ., Tallahassee.]

When β-3-thienyl-DL-alanine or DL-propargylglycine was given to rats there was a significant decrease in liver xanthine oxidase. This was shown by paired feeding experiments to be only partly due to lower food intake. The recovery of enzyme activity after a standard basal diet was given to rats depleted of protein was inhibited by the inclusion of thienylalanine or DL-ethionine. Phenylalanine reversed the inhibition due to thienylalanine.—A. Hepburn.

KIERMEIER, F. and VOGT, K. Ursachen unterschiedlicher Xanthindehydrase-Aktivität in Kuhmilch aus verschiedenen Anlieferungsbezirken. [**Causes of differences in xanthine dehydrase activity in cow's milk from different districts.**] *Ztschr. Lebensmittel - Untersuch. Forsch.*, 1956, **103,** 355–361. [Süddeutsch. Versuchsanst. Milchwirtsch., Weihenstephan.]

Mixed milk samples from a 2000-litre container at the creamery showed considerable variations in xanthine dehydrase activity. Samples from churns showed even greater variation and especially low values. From 264 individual herd samples during winter feeding and 277 during summer it was found that more low values occurred in winter. The mean activity was higher in herds on alkaline soils than in those on acid soils. The possibility that the difference depends on the lower availability of Mo in acid soils is discussed.—D. Duncan.

ERICSON, L. E. and HARPER, A. E. **Effect of diet on the betaine-homocysteine transmethylase activity of rat liver. 1. Amino acids and protein.** *J. Biol. Chem.*, 1956, **219**, 49–58. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

1. The betaine-homocysteine transmethylase activity of rat liver rose when the protein in the basal diet was increased from 9 to 18 per cent. casein. Supplements of threonine or tryptophan increased the activity to a slighter extent. Tryptophan, in contrast to the findings of Dinning *et al.* (Abst. 3452, Vol. 24), was not particularly important, nor was the activity negligible when the diet contained adequate methionine. The increases were generally accompanied by increases in liver protein and decreases in liver fat. The enzyme activity of liver from rats on the basal diet decreased for 3 weeks, then gradually increased until the seventh week. Liver protein showed a similar trend, but liver fat varied inversely with enzyme activity.

The apoenzyme stimulated activity when it was low. Growth was retarded by excess leucine, methionine or tryptophan, but not by *iso*leucine. In all these rats and in fasted rats the weight and total protein content of the liver decreased, but the enzyme activity increased.

For part 2 see Abst. 4455, Vol. 26.

MORI, K. **Cholesterol esterase activity of the reproductive endocrine gland in the essential fatty acids-deficient rat.** *J. Vitaminol., Japan*, 1956, **2**, 12–17. [Lab. Physiol. Chem., Fac. Agric., Univ. Tottori.]

Weanling rats were given a purified diet with or without essential fatty acids. Animals were killed every 10 days for 80 days. Homogenates of adrenal, testis and ovary were examined for cholesterol esterase activity.

Homogenates from rats deprived of essential fatty acids showed low cholesterol esterase activity, especially in adrenal tissue. The cholesterol esterifying system was always affected more than the cholesterol ester hydrolysing system.

FARRELL, J. H. **The effect of mastication on the digestion of food.** *Brit. Dent. J.*, 1956, **100**, 149–155. [Sutherland Dent. Sch., Newcastle upon Tyne.]

Twenty-nine foods were tested by 10 healthy adults whose ability to masticate was assessed by the method of Manly and Braley (*J. Dent. Res.*, 1950, **29**, 448). Two specimen cubes of the food, volume about 1 c.c., were weighed and one was chewed thoroughly, 20 times if necessary. Each was then sewn into a bag of open (1·5 mm.) cotton mesh, with a ball-bearing as marker, and the 2 bags were tied together and swallowed as part of an ordinary meal. On recovery from the faeces the bags were washed gently and the contents, if any, were examined and weighed. Tests in which the time of passage exceeded 40 hr. were rejected.

The following foods left large undigested residues if unchewed and might leave some residues even if chewed: pork, roast or fried; fried bacon; beef, roast, fried or stewed; mutton, roast or stewed; lamb, roast or fried; potatoes, fried or boiled, old or new; boiled peas; boiled carrots. Roast chicken and stewed lamb were more digestible, and the following usually left no residue even if unchewed: beef fat, fried or stewed; cod, fried or boiled; fried kipper; hard-boiled egg; boiled rice; bread, white or wholemeal; Cheddar cheese. The results with different subjects were strikingly similar. Further tests on fried pork with subjects who wore full or partial dentures, or chewed with incisors only, showed that digestion was not affected by reduction of efficiency of mastication.

FARRELL, J. H. **The effect on digestibility of methods commonly used to increase the tenderness of lean meat.** *Brit. J. Nutrition*, 1956, **10**, 111–115. [Sutherland Dent. Sch., Newcastle upon Tyne.]

In each of 58 experiments with 1 female and 5 male subjects aged from 24 to 33 years, 2 weighed portions of fried beefsteak, taken from similar portions of meat treated by different tenderising methods, were sewn into separate cotton-mesh bags, which were then tied together and swallowed. On recovery from the faeces any residues contained in the bags were examined and their weights were compared. Five methods which may be used to improve the tenderness of meat were tested, namely, soaking the meat for 12 hr. in diluted vinegar, treating the meat with papain, salt and sugar in the form of a proprietary meat tenderiser called Meatendra, beating the meat with a rolling pin or with a spiked hammer, and beating the meat with a spiked hammer and then treating it with Meatendra.

Two of the methods tested, soaking in vinegar solution and beating with a rolling pin, had no significant effect on the digestibility of the meat. The spiked hammer increased the digestibility by 28 per cent., Meatendra increased it by 16 per cent., and a combination of the spiked hammer and Meatendra increased it by 37 per cent. It is suggested that the effectiveness of the spiked hammer method in influencing digestibility is due to an increase in the surface area of the meat.

CASTLE, E. J. **The rate of passage of foodstuffs through the alimentary tract of the goat. 2. Studies on growing kids.** *Brit. J. Nutrition*, 1956, **10**, 115–125. [Dept. Vet. Prevent. Med., Univ. Liverpool.]

For part 1 see Abst. 3140, Vol. 26.

2. The rate of passage of stained hay increased up to weaning and then remained fairly constant. When strained faecal residues were given by mouth the markers first appeared in the faeces at the same time. The remainder of the stained faecal fragments were excreted more rapidly than the stained hay, which suggested that the larger particles of hay were retained in the reticulo-rumen for a longer time. Dry matter content of faeces, in general, increased progressively with age and was correlated positively with excretion time of 5 per cent. of stained particles and negatively with total water intake.—F. C. Aitken.

4518

CASTLE, E. J. and CASTLE, M. E. **The rate of passage of food through the alimentary tract of pigs.** *J. Agric. Sci.*, 1956, **47,** 196–204. [Fac. Vet. Sci., Univ. Liverpool.]

Small amounts of pig meal stained with basic fuchsin or brilliant green were added to rations of one sow and 4 fattening pigs. The stained particles were counted as they appeared in faeces collected at fixed intervals after feeding, and excretion curves were plotted. These curves were sigmoid in shape and from them were obtained the mean retention times of the stained particles in the digestive tract.

The times between feeding and the excretion of 5 and 95 per cent. of the stained particles were for fattening pigs 21 hr. and 53 hr. and for sows 38 hr. and 68 hr. The mean retention time in hours of all the stained particles in the entire tract was for fattening pigs on the average 34·2 hr., for sows 51·1 hr. The time was significantly shorter for a marker in the morning feed than in the evening feed.

With the fattening pigs there was no statistically significant relation between mean retention time and liveweight, digestibility of the ration, or dry matter content of the faeces.—I. A. M. Lucas.

MANGOLD, E. and BEHM, G. Zur Frage der Durchgangszeiten beim Kaninchen, besonders unter dem Einfluss des Rohfasergehaltes im Futter. [**Time of passage (through the intestinal tract) in rabbits, especially as affected by the crude fibre content of the feed.**] *Arch. Tierernährung*, 1956, **6,** 35–43. [Inst. Tierernährungslehre, Humboldt Univ., Berlin.]

Six rabbits each received 120 g. daily of a diet of dried yeast, haymeal and cooked potatoes in which the percentage of hay, providing fibre, was 10, 20 or 30. They were fed twice daily. For labelling of contents each rabbit received on the 6th day 2000 particles of straw chaff stained with fuchsin, made up into tablets with rye flour and water. These were later counted in diluted faeces. Three rabbits were used in each experiment. They wore collars to prevent coprophagy.

There was no significant difference in transit time of labelled particles which could be related to the hay content of the diet.—D. Duncan.

4520

JUKES, H. G., HILL, D. C. and BRANION, H. D. **Effect of antibiotic on the rate of passage of feed marker through the digestive tract of the chick.** *Poultry Sci.*, 1956, **35,** 232–234. [Dept. Nutrit., Ontario Agric. Coll., Guelph.]

In 9 experiments supplements of 10 p.p.m. procaine penicillin G or aureomycin hydrochloride were given to chickens 2½ to 3½ weeks old, and rate of passage of feed was estimated with carmine in capsule or water suspension as a marker. In all experiments the antibiotic increased rate of passage of the feed through the intestinal tract, though not always significantly at the 0·5 per cent. level of probability. When penicillin was removed from or added to the ration the effect was observed between 17 and 71 hr. after the change.

MERTEN, R. and FETSCHER, W. Beziehungen zwischen Gesamtausscheidung und Konzentration von freier Salzsäure, Pepsin und Kathepsin in der Basalsekretion, nach Histamin und Insulin. [**Relations between total secretion and concentrations of free hydrochloric acid, pepsin and cathepsin in fasting gastric secretion after histamine and insulin.**] *Ztschr. ges. exp. Med.*, 1956, **127,** 133–152.

Gastric juice was collected every 15 min. for an hour from 100 subjects who had fasted for 16 hr. In 50 subjects collection continued for another hour after injection of histamine and in 30 after injection of insulin. The volume, total free HCl, total pepsin and total cathepsin of the gastric juice were estimated, and correlations were examined statistically.

In the fasting secretion there were statistically significant positive correlations between total output of free HCl and pepsin or cathepsin, between pepsin and cathepsin relative to volume and between the concentrations of pepsin and cathepsin. There was no correlation between concentration of free HCl and of enzymes.

Both histamine and insulin increased total volume and total output of acid and enzymes. Free HCl concentration increased after histamine, that of enzymes possibly increased. After insulin concentrations of both HCl and enzymes increased. The mechanisms of action of histamine and insulin are discussed.—D. Duncan.

4524

HOFFMANN, W. Die Zehnuhr-Zwischenmahlzeit in der Schule. Untersuchungen über die Magenverweildauer von Milch und Äpfeln, mit und ohne Brot. [**The 10 o'clock snack in**

schools. Length of stay in the stomach of milk and apples with and without bread.] *Schweiz. med. Wochenschr.*, 1956, **86,** 733–734. [Dufourstrasse 28, St. Gallen.]

Complaints were made by mothers that mid-morning milk deprived the children of appetite for dinner. Apple was recommended instead as containing vitamins, mineral salts, organic acids and easily absorbed carbohydrates, since the Swiss child's diet was held to include too much milk and too little fruit. A study was published in 1952 (Abst. 1078, Vol. 22), showing that apple left the stomach more quickly than milk or bread. The results were questioned by Wild (*Schweiz. med. Wochenschr.*, 1954, **84,** 298) and further tests have therefore been made, in which 10 g. barium sulphate with 200 ml. milk or 200 g. apple were given at 10 a.m. on successive days to 45 children aged from 7 to 15 years. The stomach was examined radiologically between 12.15 and 12.30. The pictures showed for the milk and apple, respectively, children with stomach empty 4 and 36, partly empty 8 and 8, and full 33 and 1. A similar test with 17 children given on 4 successive days milk and apple as before, with or without 50 g. bread, showed that bread tended to retard emptying so that the numbers with quite empty stomach were milk and bread 0, milk 2, apple and bread 9, and apple 17.—E. M. Hume.

4525

SCHAPIRO, H. and WOODWARD, E. R. **Inhibition of gastric motility by acid in the duodenum.** *J. Appl. Physiol.*, 1955, **8,** 121–127. [Dept. Surg., Univ. California, Los Angeles.]

Movements of the stomach and duodenum were recorded from balloons in 26 human subjects. When 0·1 *N* HCl was introduced into the duodenum in 7 patients with duodenal ulcer, 2 with vagotomy and pyloroplasty, 2 with lumbar sympathectomy, 3 with splanchnic sympathectomy and 2 with destructive lesions of the lower thoracic spinal cord, there was always rapid inhibition of gastric motility, which lasted up to 40 min. or more. In some subjects the same effect was produced by acid in the jejunum. Duodenal motility was affected in some tests, but not in all. In one subject 0·1 *N* H_2SO_4 was as effective as HCl. In 2 patients with ileostomy and 2 with colostomy, introduction of HCl into terminal ileum or colon had no effect on gastric motility. Physiological saline in the duodenum rarely affected gastric motility, and when it did so the effect was transitory.—D. Duncan.

4526

HUNT, J. N. **Some properties of an alimentary osmoreceptor mechanism.** *J. Physiol.*, 1956, **132,** 267–288. [Dept. Physiol., Guy's Hosp., London, S.E.1.]

The properties of the postulated osmoreceptors in the duodenum have been tested by extensive measurements of gastric emptying time in man after a variety of test meals had been introduced into the stomach. Water produced more rapid emptying than a solution containing sucrose. With NaCl solution with up to 100 m. equiv. per litre, the rate of emptying rose with concentration, but concentrations of 160 to 350 m. equiv. per litre caused a progressive decrease. Similar results were obtained with $NaHCO_3$ or urea solutions; but glucose, sorbitol or KCl caused a steady decrease in the rate of emptying as the concentrations increased. It is postulated that the receptors are impermeable to potassium and the sugar used but not to the sodium chloride and bicarbonate ions.—A. T. Phillipson.

4527

MOXON, A. L. and BENTLEY, O. G. **Research on rumen function and ruminant nutrition.** *Trans. Amer. Assoc. Cereal. Chem.*, 1955, **13,** 15–30. [Dept. Animal Sci., Ohio Agric. Exp. Stat., Wooster.]

4528

SMITH, P. H., SWEENEY, H. C., ROONEY, J. R., KING, K. W. and MOORE, W. E. C. **Stratifications and kinetic changes in the ingesta of the bovine rumen.** *J. Dairy Sci.*, 1956, **39,** 598–609. [Dept. Statistics, Virginia Agric. Exp. Stat., Blacksburg.]

Three steers with rumen fistulae were offered grain and hay to appetite and surplus feed was removed after the evening meal before experiments. For experiments the animals had in the morning 2 lb. grain and all the hay they could eat in 1 hr. and samples of ingesta were taken from top and bottom of the rumen, and in some experiments also from the middle, before and every hour for 12 hr. after the feed. In some trials the animals had a second feed 8 hr. after the first.

Ingesta from the top of the rumen were generally higher than bottom samples in total N, N.P.N., organic N.P.N., ammonia, water- and alcohol-soluble sugars, volatile fatty acids and crude fibre, but lower in ether extract, *p*H and ability to digest cellulose *in vitro*. The differences were all statistically significant, except possibly that in concentration of alcohol-soluble sugars. Similar results were obtained with ingesta removed under local anaesthesia from a cow without a fistula, showing that the stratification was not due to the presence of the fistula.

The statistical and physiological interpretations of the results are discussed.—D. Duncan.

4529

HUNGATE, R. E. and DYER, I. A. **Effect of valeric and isovaleric acids on straw utilization by steers.** *J. Animal Sci.*, 1956, **15,** 485–488. [Dept. Bacteriol. Pub. Health, State Coll. Washington, Pullman.]

When bullocks were fed on a ration containing 82 per cent. wheat straw, the addition of 8·44 g. valeric and 2·75 g. *iso*valeric acid per 60 lb. feed made the ration more palatable, but feed intake was controlled, and the total amount of feed eaten with and without the acids was similar. Weight changes of the bullocks were similar, and digestibility of crude fibre in the ration was not affected by the addition of the acids.

Manometric studies of fermentation in contents extracted from the rumen showed less activity in bullocks given the acids than in the others. When hay was added to incubated rumen contents the rate of fermentation was about the same in all animals. It is suggested that the results may have been due to lack of fermentable carbohydrate in the ration, and this is discussed.—T. D. Bell.

4530

EVANS, R. E. and MAGUIRE, M. F. **The influence of dietary antibiotics on the activity of the cellulose-splitting bacteria in the intestine of the bacon pig.** *J. Agric. Sci.*, 1956, **47,** 344–349. [Sch. Agric., Univ. Cambridge.]

Of 4 littermate pigs 2 were fed on bran, maizemeal, white fish meal and lucerne meal, and the other 2, which had been receiving penicillin since weaning, were given the same feed supplemented with 18 mg. procaine penicillin per lb. feed. Digestibilities were studied by comparative analyses of faeces and feed for 12 days.

Both pairs were then given daily, mixed with the feed, 500 g. cellulose prepared from wheat straw by the method of Woodman and Evans (Abst. 3898, Vol. 17). Digestibility trials were continued for 12 days. Penicillin was next given for 12 days to the pair of pigs which had previously been without it, in order to detect any temporary effect of the antibiotic. The penicillin was then replaced by aureomycin hydrochloride, 5 mg. per lb. ration, during 9 days. Results of analyses made in the last experiment were confirmed with 2 other pigs given cellulose in the ration, one without and one with aureomycin.

Detailed results for digestibility trials in each experiments are given. The digestibility of no feed constituent was altered by antibiotic. Digestibility of the cellulose product remained high, the mean digestion coefficients for crude fibre in each experiment lying between 92·8 and 95·9 per cent., and when N-free extractives, probably largely xylan, were included the values were about 85 per cent. Addition of cellulose reduced the digestibility of protein and much gas was produced, but these effects also were independent of either antibiotic.—J. C. Appleby.

4531

WISEMAN, R. W., BUSHNELL, O. A. and ROSENBERG, M. M. **Effect of rations on the pH and microflora in selected regions of the intestinal tract of chickens.** *Poultry Sci.*, 1956, **35,** 126–132. [Dept. Bacteriol., Univ. Hawaii, Honolulu.]

Two groups of 12 six-week-old pullets received grower's rations differing only in that one contained 58·5 per cent. yellow maizemeal and the other 53 per cent. molasses and 5·5 per cent. bagasse pith as their main sources of carbohydrate. All the pullets were fed for 11 days and then 3 from each group were killed weekly for examination of microflora and *p*H of the digestive tract.

The ration had little effect on *p*H in any part of the digestive tract. The contents were very acid until they reached the duodenum, where there was a sharp rise of *p*H, and the *p*H continued to rise until the posterior small intestine was reached.

Bacterial counts of aerobes and lactobacilli from all parts of the tract were smaller with molasses than with maizemeal and tended to rise and fall with *p*H. The molasses ration as eaten contained more lactobacilli than the maize ration.

D. Duncan.

4532

AUGUSTE, C., SWYNGEDAUW, J., GUERRIN, F. and ROHART, J. L'absorption jéjunale après gastrectomie. Recherches faites au moyen de l'iode radioactif. [**Absorption from the jejunum after gastrectomy. Investigation with radio-active iodine.**] *Arch. Mal. Appar. diger.*, 1956, **45,** 181–188. [Lille.] English summary.

The rate of absorption was measured with radioactive NaI in doses equivalent to 500 μC. ^{131}I and containing 5 μg. iodine, in 15 patients after gastrectomy and in 20 normal subjects. The radioactivity of plasma from peripheral blood and of the thyroid was studied frequently during the hour after the test dose. In plasma the degree of radioactivity after the test dose was always greater when the patient was examined in the sitting position than in the recumbent position, in normal euthyroid subjects and in gastrectomised patients; in the gastrectomised subjects examined sitting, the rise in radio-activity was much greater and appeared earlier than in normal subjects or in recumbent gastrectomised subjects. Measurements of radio-activity in the thyroid gave similar but less precise results. It is concluded that the main cause for the increased rate of absorption by the jejunum after gastrectomy is the acceleration of passage.—L. Wills.

4533

KERPEL-FRONIUS, E., MESTER, A., SZY, S., BARKA, I., ZSÁMÁR, E. and KELEMEN, I. **Enteral absorption in experimental anhydraemia and hypothermia.** *Acta physiol. hung.*, 1955, **7,** 103–111. [Dept. Paediat., Med. Sch., Univ. Pécs.] Russian summary.

Absorption of glucose, sodium thiocyanate and oil was studied in rats by the technique of Cori (*J. Biol. Chem.*, 1925, **66,** 691). In some animals anhydraemia equal to medium-grade shock was induced by the method of Darrow and Yannet (Abst. 677, Vol. 5); others were cooled in suitable water-baths, and there were untreated controls. Average values for percentage of glucose absorbed, total glycogen in liver in mg. and blood sugar in mg. per 100 ml. were, in normal animals after 3 hr., 96·6, 107 and 150, and in anhydraemic rats after 3 hr., 34·0, 22 and 184, and after 5 hr., 63·0, 17 and 158. In normal and anhydraemic rats, respectively, averages for absorption of NaCNS after 3 hr. were 71·7 and 76·0 and of oil after 6 hr. 47·0 and 9 per cent. Data for glucose absorption, in the same order as above for anhydraemia, were, with rectal temperature 34° C., 85·0, 15 and 164, at 27° C., 40·0, 17 and 125 and at 20° C., 14·0, 10 and 76. For NaCNS at 21° C. absorption was 50·0 and for oil at 30° C. 14 and at 26° C. 3·3 per cent.

The results are discussed and, except at the lowest temperature, which is unlikely to be reached, similar interference with absorption is thought likely to occur in patients in whom there are similar fluid and temperature changes.—D. Harvey.

LARSEN, H. J., STODDARD, G. E., JACOBSON, N. L. and ALLEN, R. S. **Digestion and absorption of various carbohydrates posterior to the rumino-reticular area of the young bovine.** *J. Animal Sci.*, 1956, **15,** 473–484. [Iowa State Coll., Ames.]

Three male calves, aged 8 to 9 months, with rumen and caecal fistulae, were given 4 experimental diets directly into the omaso-abomasal cavity. Each diet was given for 2 days and the order of the diets was different for each animal. The diets differed in carbohydrate, which was maize, maize starch, maltose or glucose. For digestion experiments 1 per cent. chromium oxide was added to the diet.

Digestion studies and levels of reducing sugar in the blood indicated that glucose and maltose were readily absorbed, but there was little digestion of starch or of carbohydrate in maize.

In studies with isolated visceral sections in 2 of the animals there was ready absorption of glucose from jejunum and ileum and less efficient absorption from rumen and caecum.—F. C. Aitken.

4535

PACKHAM, M. A. **The absorption of labelled glucose, sodium glucuronate, and glucurone from the gastrointestinal tract of the rat.** *Canad. J. Biochem. Physiol.*, 1956, **34,** 587–591. [Dept. Biochem., Univ. Toronto, Ont.]

The rate of excretion of ^{14}C as CO_2 in the expired air and the residues of ^{14}C in the stomach, small intestine and large intestine were measured at intervals after glucose, glucuronate or glucurone labelled with ^{14}C was given to rats by stomach tube. The results showed that most of the glucose was absorbed rapidly from the small intestine, but a time lag occurred with glucuronate and glucurone and their ^{14}C was not absorbed before the large intestine. It was concluded that very little of these compounds is absorbed and that decomposition occurs in the large gut.

A. T. Phillipson.

MAYER, J. and YANNONI, C. Z. **Increased intestinal absorption of glucose in three forms of obesity in the mouse.** *Amer. J. Physiol.*, 1956, **185,** 49–53. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

The mice included animals with hereditary obesity and diabetes and their non-obese littermates, Swiss females with obesity produced by injection of gold thioglucose or by hypothalamic lesions, and mice operated on but not obese. For experiments the mice were fasted for 20 hr. and then given by stomach tube 50, 100, 200 or 400 mg. glucose in 0·5 ml. solution. They were killed 30 min. later for a study of absorption.

Absorption of glucose by non-obese mice reached a plateau at a dose of 100 mg. in littermates of genetically obese mice and at 200 mg. in other controls. With all 3 types of obesity absorption continued to increase with the dose. The amount absorbed by obese mice was consistently greater than that absorbed by controls, despite blood sugar values, in the genetically obese group, considerably above the normal. The amount of glucose recovered in the stomach after 30 min. was of the same order in all groups, so the differences are ascribed to differences in intestinal absorption as such. Of that glucose which had reached the intestine the percentage absorbed was considerably higher in obese mice than in their controls, though it was less in the obese diabetic mice and their littermates than in the Swiss mice, obese or not. When obese and control mice of all types were underfed or given for a week a high-fat, carbohydrate-free diet, there was a tendency for absorption of sugar to be less, but the difference was significant only in mice with hypothalamic obesity.—D. Duncan.

HARTMANN, F., LENZ, H., LOPEZ-CALLEJA, C. and MÜNZENBERG, H. Die Resorptionsweise von Aminosäuren aus dem Dünndarm. [**Mode of absorption of amino acids from the small intestine.**] *Arch. exp. Pathol. Pharmakol.*, 1956, **228,** 403–413. [Med. Klin., Univ. Göttingen.]

The 16 dogs used were mostly about 20 to 25 kg. in weight. They were anaesthetised and a cardiac catheter was passed from the jugular into the hepatic vein. In small dogs a transfusion was set up into the femoral vein, and in 3 dogs a cross circulation was established between the mesenteric artery and the femoral vein of another dog. The dogs were heparinised and the upper part of the small intestine was exposed and clamped at both ends of a loop 40 to 50 cm. long. An injection of 100 ml. 50 per cent. amino acid solution (Aminovit) was given into this loop, which was then replaced in the abdominal cavity. Blood samples of 10 ml. were taken from the mesenteric and hepatic veins at intervals up to 120 min. Arterial blood was taken also from some dogs. Amino acids were estimated by paper chromatography of serum. The mixture administered contained, per cent., lysine + ornithine 6·8, cystine + cysteine 3·1, glutamic acid 9·1, aspartic acid + arginine 9·8, glycine 5·2, serine 7·0, alanine 8·1, threonine 6·4, valine 12·8, methionine 6·9, leucine + *nor*leucine + phenylalanine + tryptophan 12·4, *iso*leucine + tyrosine 9·6 and proline 2·8.

Absorption began within 5 min. of administration of the amino acid mixture. The rate of absorption of individual amino acids was not closely related to their concentration in the intestine. Glutamic acid and proline were absorbed at much the same rate.

The course of absorption was not the same for all amino acids. There were 3 peaks of absorption, one in the first 15 min., one at about 35 to 40 min. and the third after about 1 hr. The concentration of amino acids in the hepatic vein hardly rose at all, but some amino acids rose slowly, though in no quantitative relation to their concentration in the mesenteric vein.

As absorption of individual amino acids was not related to their molecular weight, their diffusion constant or the concentration gradient between the intestinal contents and the portal blood, it must be an active process. The liver removes amino acids selectively from the portal blood.—D. Duncan.

4538

HARTMANN, F., LENZ, H., LOPEZ-CALLEJA, C. and MÜNZENBERG, H. Über die Serumeiweissfraktionen des Pfortader- und Lebervenenblutes während der Resorption eines Aminosäuregemisches aus dem Darm. [**Serum protein fractions in the blood of portal and hepatic vein during absorption of a mixture of amino acids from the intestine.**] *Arch. exp. Pathol. Pharmakol.*, 1956, **228,** 414–420. [Med. Klin., Univ. Göttingen.]

The experiments were those described in the preceding Abst. Serum proteins were studied refractometrically and by micro-electrophoresis in blood from the portal and hepatic veins. The results are given in tables and a graph. There were always slight differences in composition between serum proteins in blood entering and leaving the liver.—D. Duncan.

4539

TIDWELL, H. C. **Effect of choline, methionine and ethionine on fat absorption.** *J. Nutrition*, 1956, **58,** 569–578. [Dept. Biochem., Univ. Texas Southwestern Med. Sch., Dallas.]

Fasting adult albino male rats were each given by stomach tube 0·3 ml. olive oil per sq. decimetre body surface followed by an intraperitoneal injection of a solution of either DL-methionine, choline chloride, prostigmine, Mecholyl or saline. A blood sample was taken before the olive oil was given and subsequently hourly for 3 hr. for chylomicron counts. In further similar experiments the animals were killed 3 hr. after the administration of olive oil and the unabsorbed fat was recovered from the gut and weighed. Chylomicron counts were made also on the blood of animals which were given repeated injections of methionine, choline or ethionine with or without previous administration of olive oil by mouth.

It was concluded that fat absorption was promoted by choline ; prostigmine and Mecholyl did not affect the rate of absorption, suggesting that the choline effect may be due to increased synthesis of lecithin. Methionine promoted absorption of olive oil to a slight extent. Significantly increased blood fat values were found also after administration of ethionine.—G. A. Garton.

WOLFF, R. and BRIGNON, J. J. Recherches expérimentales sur la résorption intestinale du cholestérol chez le lapin. [**Experimental research on absorption of cholesterol from the intestine of the rabbit.**] *Bull. Soc. Chim. biol.*, 1956, **38,** 99–109. [Lab. Chim. Biol., Fac. Méd., Nancy.] English and German summaries.

Serum cholesterol was estimated in groups of normal rabbits at intervals, and was shown to be constant. Cholesterol was then given by mouth as a solution in cottonseed oil or oleic acid or as a component of an emulsion containing arachis oil and bile salts. Maximum values for serum cholesterol were obtained 24 hr. after administration of

the cholesterol. Cottonseed oil or arachis oil emulsion alone did not affect serum cholesterol, but oleic acid alone at 3 ml. per kg. bodyweight reduced serum cholesterol.

In further experiments serum cholesterol was estimated before and 24 hr. after oral administration to rabbits of cholesterol alone or with soya bean sterols. The inhibitory effect of soya bean sterols on absorption was reflected in lower serum cholesterol values after 24 hr.—G. A. Garton.

4541

FRIEDMAN, M., ROSENMAN, R. H. and BYERS, S. O. **The effect of beta-sitosterol upon intestinal absorption of cholesterol in the rat.** *Circulation Res.*, 1956, **4**, 157–161. [Harold Brunn Inst., Mount Zion Hosp., San Francisco, Calif.] Interlingua summary.

In contrast to the findings of Hernandez *et al.* (Absts. 585, Vol. 24; 3669, Vol. 25), β-sitosterol had only a slight retarding effect on the absorption of cholesterol by the rat.—A. Hepburn.

4542

BENSON, J. A. (Jr.), LEE, P. R., SCHOLER, J. F., KIM, K. S. and BOLLMAN, J. L. (with VAN HOOK, E. and ANDERSON, J.) **Water absorption from the intestine via portal and lymphatic pathways.** *Amer. J. Physiol.*, 1956, **184**, 441–444. [Sect. Biochem., Mayo Found., Rochester, Minn.]

D_2O and ^{24}Na were given in saline solution by stomach tube to rats in which the mesenteric lymphatic was cannulated and portal blood and femoral arterial blood were collected. Nearly all the isotope passed into the portal bloodstream, the amount in the lymph was proportional to the lymph volume and the concentrations were practically identical with that in arterial plasma, whether the isotope was given by stomach tube or by injection into the arterial or portal system.

A. T. Phillipson.

4543

DONNET, V. and GARNIER, L. Facteurs endocriniens de l'absorption intestinale de l'eau et du chlorure de sodium. [**Endocrine factors in intestinal absorption of water and sodium chloride.**] *C.R. Acad. Sci.*, 1956, **242**, 2401–2403.

Eleven dogs with Thiry Vella loops 50 cm. long in the upper part of the small intestine were trained to maintain Pavlov's position without restraint during experiments. The loop was perfused at constant rates with NaCl solutions of different concentration, and the mean absorption in successive 10-min. intervals was studied. Each dog was used 2 or 3 times a week, for one week or more, to obtain a standard for that dog, and then different modifications were introduced.

Solutions with less than 0·1 or more than 1·6 per cent. NaCl gave irregular results. Solutions of 0·5 or 0·6 per cent. were most rapidly absorbed, and in those of 0·6 to 0·8 per cent. the concentration remained unchanged. During digestion, absorption of water increased by from 11 to 17 per cent., but absorption of NaCl was not changed. Injection of from 25 mU. to 10 U. posterior pituitary extract increased absorption of both water and NaCl, the haematocrit showed haemodilution and intestinal motility was reduced. Section of the supra-optic-hypophyseal tract reduced absorption of water, greatly increased absorption of NaCl and haemodilution.

Thyroxine had a variable effect on the absorption of water, reduced absorption of NaCl by 40 per cent. and caused haemodilution. Removal of the thyroid or treatment with antithyroid substances caused a small decrease in absorption of water, a larger decrease in absorption of NaCl and haemoconcentration of 10 per cent.

Female sex hormones increased absorption of water and haemoconcentration, but oestradiol gave equivocal results. Pregnancy gave a similar effect on absorption, but with haemodilution. Deoxycorticosterone acetate had no effect when the diet was normal, but when it followed a salt-deficient diet it increased absorption of both water and NaCl. During "phenomena of physical thermoregulation" [the conditions are not defined] absorption of water and of NaCl increased significantly only in athyroid dogs.—D. Duncan.

DONALDSON, J. S., WRATNEY, M. J., PASCASSIO, A., WEIGAND, F. A. and DANOWSKI, T. S. **8. Trials of protein hydrolysate, vitamin supplements and physical therapy.** *Amer. J. Dis. Child.*, 1956, **91,** 326–338; 339–345; 346–355; 356–364; 429–435; 436–441; 442–448; 449–453. [Child. Hosp., Sch. Med., Pittsburgh, Pa.]

1. Thirty-one children with a history of motor weakness suggestive of muscular dystrophy were studied. Muscle biopsy specimens were obtained from 22. In general all the muscle groups tested for motor strength showed impairment. There was a high positive correlation between biopsy findings and clinical status in patients with muscle strength reduced below 50 per cent. of normal, but histological changes appeared to precede clinical deterioration. Motor strength was not further impaired by biopsy.

2. Changes in long bones, spine and soft tissues in muscular dystrophy are described. All of these, except those in the soft tissues of the calves, were attributable to prolonged disuse.

3. Blood findings in the 31 patients with muscular dystrophy were compared with those in a non-dystrophic control group. The only noteworthy differences were that serum Ca and P were significantly higher and cholesterol and Cl were lower than normal in muscular dystrophy.

4. Serum corticosteroids, urinary gonadotropin and 17-ketosteroids and response to blood sugar tolerance tests were within the normal range. Serum protein-bound I tended to be high and capillary blood sugar change after insulin by vein was less in muscular dystrophy than in normal subjects.

5. The blood sugar response to insulin or glucose was the same in children with muscular dystrophy as in normal controls. When both insulin and glucose were given the dystrophic children became hyperglycaemic and control children became hypoglycaemic. With insulin given alone or in combination with glucose the fall in serum inorganic P, K and bicarbonate was less in dystrophic children than in controls.

6. Adrenaline injected subcutaneously produced a small hyperglycaemic response and smaller decreases in serum inorganic P, K and bicarbonate in dystrophic children than in normal controls.

7. Pituitary growth hormone given daily for 6 to 8 months produced no clinical improvement in 4 children with muscular dystrophy. The growth hormone did not cause changes in serum and blood constituents, nor did it influence N or electrolyte balance. It had no diabetogenic effect, did not stimulate thyroid, adrenal or gonads and did not alter blood volume or clotting time.

8. Treatment with protein hydrolysates and vitamins, with or without physical therapy, for up to 1 year or more produced no objective evidence of improvement in motor power of children with muscular dystrophy. Deterioration occurred in some.—F. C. Aitken.

IVES, M. and DACK, G. M. **"Alarm reaction" and normal blood picture in Macaca mulatta.** *J. Lab. Clin. Med.*, 1956, **47**, 723–729. [Res. Div., American Can Company, Chicago, Ill.]

Mean values with standard errors are given at 3-month intervals for bodyweight, Hb value, and red cell, white cell and differential counts of 36 young healthy monkeys (*Macaca mulatta*) of both sexes maintained in a colony for a year. The stock diet consisted of half an orange, 3 slices of whole wheat bread soaked in whole milk to which 1 ml. cod liver oil was added, and kibbled dog food to appetite, with 0·5 g. of 1 : 20 dried liver powder in 30 ml. water weekly by stomach tube. Six food supplements [not specified here] were given by stomach tube. For this purpose and for other tests the monkeys were put in a new type of adjustable restraining box, padded with foam rubber, which is described in detail, with illustrations. A big fall in white cell count after 3 months is ascribed to lessening of the "alarm reaction" by this method of restraint. Hb value and red cell count changed slightly with age, and Hb value, but not red cell count, was affected by the food supplements.—W. M. Deans.

4549

SCHLICHTING, M., SANDERS, R. and GARDNER, M. **The blood picture of 200 Thoroughbreds.** *Vet. Med.*, 1956, **51**, 151. [Vet. Diagnostic Labs., 220 East 23rd St., New York.]

Average Hb values for 57 yearlings, 114 horses in training, 3 to 5 years old, and 29 brood mares and stallions were 14·0, 15·0 and 14·8 g. per 100 ml., respectively. Erythrocyte counts were 11,936,000, 11,344,290 and 10,900,500, and white cell counts 10,530, 10,286 and 10,035. The distribution of the types of white cell is shown.

BRENON, H. C. **Erythrocyte and hemoglobin studies in Thoroughbred racing horses.** *J. Amer. Vet. Med. Assoc.*, 1956, **128**, 343–345. [Brenon Lab., Inglewood, Calif.]

4551

HOLMAN, H. H. **Changes associated with age in the blood picture of calves and heifers.** *Brit. Vet. J.*, 1956, **112**, 91–104. [Agric. Res. Counc. Field Stat., Compton, Berks.]

The blood picture in calves from birth to 2 years old was studied. Red cells were smaller at birth than in cows, and decreased in size for 2 months; then there was a gradual increase until adult size was attained at 2 years old. Red cell count at birth was 8 million per c.mm., and fell to the adult level of 6 million (see Abst. 1868, Vol. 26), rapidly for 4 months, and then gradually to 1 year old. Packed cell volume was 42 per cent. at birth, and fell to 35 per cent., the adult value, within 4 months. Hb was 13 g. per 100 ml. at birth, but rapidly fell, so that the level found in cows, 11 g. per 100 ml., was reached within a week. M.C.H.C., 31 per cent., and sp. gr., 1·051, were similar to adult values. Of the white cells, at birth lymphocytes were 33 per cent., rising to 72 per cent. at 4 months, then falling gradually to 30 per cent. at 2 years. At birth eosinophils were less than 1·0 per cent., and the rise to the adult level of 10 per cent. was slow and irregular. The findings are discussed and compared with others in the literature.—T. D. Bell.

SPINETTI-BERTI, M. Electroforesis sobre papel de filtro en condiciones normales. [**Electrophoresis on filter paper under normal conditions.**] *Acta cientif. venezol.*, 1955, **6,** 204–207. [Dept. Bioquim., Univ. de los Andes.] English summary.

Serum proteins were studied by paper electrophoresis in samples from 100 apparently normal subjects aged from 10 to 60 years, in the town of Merida. Values in g. per 100 ml. serum were: total protein 7·36, S.D. 0·52, albumin 4·49, α_1-globulin 0·25, α_2-globulin 0·56, β-globulin 0·80, γ-globulin 1·26, albumin : globulin ratio 1·6 $\pm$ 0·33.

4564

REINER, M. and SULLIVAN, M. X. **Cystine in human serum proteins.** *Clin. Chem.*, 1956, **2,** 65–74. [Chem. Lab., District of Columbia Gen. Hosp., Washington.]

Cystine was estimated by a modification of the 1 : 2 - naphthoquinone - 4 - sulphonate method of Sullivan (U.S.P.H.S. Suppl. (1929), **78,** IV, 4) in serum protein fractions prepared by the procedure of Cohn *et al.* (Title 1320, Vol. 16). Albumin contained 6·4 per cent. cystine, γ-globulin 1·94 per cent. and globulin from human haemoglobin 1·9 per cent. Values are also given for fractions from patients with multiple myeloma.—H. G. Bray.

IYER, G. Y. N. **Distribution of glutamine, glutamic acid and aspartic acid between erythrocytes and plasma.** *Indian J. Med. Res.*, 1956, **44,** 201–204. [Med. Coll., Trivandrum.]

Glutamine, glutamic acid and aspartic acid in plasma and red blood cells from 13 normal donors were estimated by paper chromatography (see Abst. 45, Vol. 26). The average concentrations, in mg. per 100 ml. red cells, were glutamine 7·19, glutamic acid 5·58 and aspartic acid 5·11. The values for plasma were 9·08 and 0·89 for glutamine and glutamic acid. Aspartic acid in plasma was estimated visually and in 6 samples was present in traces only. Red cells contained much more aspartic and glutamic acids than plasma, but glutamine was almost equally distributed when water content was taken into consideration.

DE LA HUERGA, J., DUBIN, A., KUSHNER, D. S., DYNIEWICZ, H. A. and POPPER, H. **Studies of serum mucoprotein (seromucoid). 1. A turbidimetric method.**

KUSHNER, D. S., HONIG, K., DUBIN, A., DYNIEWICZ, H. A., BRONSKY, D., DE LA HUERGA, J. and POPPER, H. **2. Physiologic variations and response to stress.** *J. Lab. Clin. Med.*, 1956, **47,** 403–408; 409–417. [Hektoen Inst. Med. Res., Cook County Hosp., Ill.]

1. Seromucoid was estimated with, as a standard, a sample of Armour's bovine serum albumin, which is a homogeneous preparation electrophoretically pure and commercially available. Agreement was good if the tyrosine method was used for the final estimation. Ranges are quoted for 95 per cent. of the subjects, 30 women and 40 men; for the women [28 or 29 is not clear] values were from 60 to 100 mg. with mean and standard deviation 77·1 $\pm$ 14 mg. per 100 ml. serum. For men they were from 55 to 105 mg. and the mean was 81·2 $\pm$ 18 mg. per 100 ml.

2. The variation of seromucoid was studied under different sets of conditions. On 4 successive days fasting levels in 18 patients in hospital did not vary by more than 5 per cent. The values at monthly intervals for 6 months in 21 men and 5 women aged from 71 to 94 years had a mean of 106 $\pm$ 21 mg. per 100 ml. serum; 95 per cent. were between 75 and 130 mg., indicating a slight rise over normal with ageing. Diurnal variation in an 8-hr. period was more than 10 per cent. of the fasting amount in 11 of 20 subjects studied; the greatest increase was by 59 per cent. of the fasting level. No effect of feeding was found in 12 patients. "Stress" was induced by injecting histamine, heat-killed typhoid bacilli, ACTH or parathyroid extract, and the changes were studied also after surgical operations. The indications were that stimulation of adrenals and breakdown of connective tissue both increased seromucoid.

VANDENBERGHEN, C. and VAN BELLE, M. De verdeling der lipoprotëinen bij normale kinderen en technik van de lipoprotëinekleuring. **[The distribution of lipoproteins in normal children and a method for staining lipoproteins.]** *Maandschr. Kindergeneesk.*, 1956, **24,** 54–59. [Afd. Kindergeneesk., Univ. Ghent.] English and German summaries.

Lipoproteins were separated by electrophoresis on paper and stained with Sudan black by the method of Swahn (*Scand. J. Clin. Lab. Invest.*,

1953, Suppl. 1, 5). Values in the blood serum of normal children from birth to 14 years of age are tabulated for total lipids, cholesterol and α_1-, α_2-, β- and chylomicron fractions of lipoproteins.

E. M. Hume.

4571

CHAPIN, M. A. **The distribution of lipid and phospholipid in paper electrophoresis of normal serum lipoproteins.** *J. Lab. Clin. Med.*, 1956, **47,** 386–391. [Dept. Med., Central Maine Gen. Hosp., Lewiston.]

Lipoproteins were studied in serum from 23 normal subjects by zone electrophoresis and the resulting bands were stained to show total lipids and phospholipins.

The β-lipoprotein fraction contained on the average 73 per cent. of the total lipid and 61 per cent. of the phospholipins. Phospholipins comprised on the average 42 per cent. of the total lipids, 38 per cent. associated with β-lipoproteins and 47 per cent. with α-lipoproteins. The lipid : phospholipin ratios for the α- and β-lipoproteins were 0·7 and 1·2.—G. A. Garton.

4572

HERBST, F. S. M., LEVER, W. F. and WADDELL, W. R. **Effects of intravenously administered fat on the serum lipoproteins.** *Science*, 1956, **123,** 843–844. [Dept. Dermatol., Harvard Med. Sch., Boston, Mass.]

Eight normal human subjects were each given a single intravenous infusion of 500 ml. of an emulsion containing 50 g. of either cottonseed oil or synthetic triolein ; 8 dogs were similarly treated with 3000 ml. of the same emulsion. Blood samples were taken before and at the end of the infusions and for several hours subsequently ; serum was subjected to paper electrophoresis and the resulting strips were stained for proteins and lipids.

The fat increased electrophoretic mobility of the α- and β-lipoproteins, and the rise persisted after the infusions had been completed. Injections of heparin during alimentary lipaemia in normal persons have a similar effect.—G. A. Garton.

4573

PAGE, I. H., LEWIS, L. A. and GILBERT, J. **Plasma lipids and proteins and their relationship to coronary disease among Navajo Indians.** *Circulation*, 1956, **13,** 675–679. [Res. Div., Cleveland Clin. Found., Ohio.] Interlingua summary.

Hospital records are quoted to show the extreme rarity of myocardial infarction among Navajo Indians. Their diet is often rich in fat and cholesterol and, in relation to the views already put forward on the origin of atherosclerosis (see Title 823, Vol. 25), blood analyses were undertaken. Samples from 2 groups of Indians in hospital with diseases known not to increase blood lipids, a younger with 12 men and 3 women, average age 31, and an older with 13 men and 8 women, average age 59 years, were compared for protein content with samples from 12 men and 15 women, average age 29½ years, in Cleveland. For the groups in that order, only the data for α_1- and α_2-globulin, 0·70, 0·68 and 0·54 g., and for γ-globulin, 1·49, 1·53 and 1·04 g. per 100 ml. serum, showed differences between the Indian and Cleveland subjects. Lipoproteins and cholesterol were measured in 36 of the Indians and compared with data for 224 control subjects in Cleveland. The S_{70-400} and S_{40-70} fractions were similar ; the mean values for cholesterol in the Indians were lower, 178 and 189, 175 and 186 mg. per 100 ml. for the younger and older men and women, respectively, than in the younger and older groups of men and women in Cleveland, 230 and 216, 242 and 230 mg., respectively.

From these results and from others with 2 strains of dwarf pigs (Lewis and Page, *Circulation*, 1956, **14,** 55) it is suggested that heredity may be of importance in determining level of cholesterol and density of lipoproteins in serum and thereby incidence of coronary disease.—D. Harvey.

4574

BERSOHN, I. and WAYBURNE, S. **Serum cholesterol concentration in new-born African and European infants and their mothers.** *Amer. J. Clin. Nutrition*, 1956, **4,** 117–123. [S. African Inst. Med. Res., Johannesburg.]

Estimations were made of total, free and esterified cholesterol in the blood of 51 African and 37 European mothers at parturition and in the cord blood of their infants. The ages of the mothers were comparable and all were healthy ; no infant weighed less than 5½ lb. The averages for total cholesterol in Africans and Europeans, respectively, were for infants 71·3 and 75·3 and for mothers 189·8 and 258·5 mg. per 100 ml. serum. Corresponding averages in the same order of race were, for free cholesterol, in infants 20·1 and 19·8 and in mothers 48·8 and 67·4 ; for esters, in infants 52·1 and 56·6 and in mothers 142·2 and 191·2 mg. For each constituent the racial difference was not significant for infants, but was highly significant for mothers. Esterified cholesterol as a percentage of total cholesterol was the same in infants, 73 and 75, and in mothers, 75 and 74, irrespective of race.

The findings are discussed in relation to race, diet, occurrence of liver disease and level of production of sex hormones, none of which is considered to account, by itself, for the differences found between African and European mothers.

D. Harvey.

4575

VAN ZYL, A. and KERRICH, J. E. **The serum lipids and age in the baboon (*Papio ursinus*).** *S. African J. Med. Sci.*, 1955, **20,** 97–117. [Dept. Physiol., Univ. Witwatersrand.]

Serum total lipids, cholesterol, lipid P and the cholesterol : lipid P ratio were studied in 44 baboons from newborn to about 13 years old and, for purposes of comparison, in 5 healthy normal persons, 7 monkeys, 7 cows, 9 dogs, 5 guineapigs, 29 rats, 12 fowls and 8 frogs.

In the sucking baboon serum total lipids were about 573 ± 69, cholesterol 200 ± 25·7 and lipid P 12·6 ± 1·5 mg. per cent.; in adult baboons serum total lipids were 470 ± 24, cholesterol 139 ± 12 and lipid P 9·6 ± 0·6 mg. per cent. From 26 estimations on 3 female baboons over 13 years of age, serum total lipids were 573 ± 61, cholesterol 160 ± 11 and lipid P 10·5 ± 2·3 mg. per cent. No significant seasonal or sex difference was found in the mean serum lipids of the baboon. The cholesterol : lipid P ratio remained constant throughout life and was independent of sex or age. The serum lipid pattern of individual baboons was restricted when compared with that of the baboon population as a whole; the within animal variance of serum lipids was 11 to 16 per cent. and the between animal variance 6 to 15 per cent. of that of the average population mean.

From the data obtained in these studies and from other data serum lipids in primates were compared with those in other animals. It was concluded that the species, strain and individual differences in blood lipids are functions not only of diet, but also of heredity.—G. A. Garton.

4576

VAN ZYL, A. **The lipid and iodine content in blood and milk of the lactating baboon; their influence on the serum lipids of the suckling infant.** *S. African J. Med. Sci.*, 1955, **20,** 119–128. [Dept. Physiol., Univ. Witwatersrand.]

Serial studies on the iodine and lipids in the blood serum and milk of 4 lactating baboons and in the blood serum of their young were made monthly during lactation. Blood samples were obtained from each young baboon directly on removal from its mother and then after 7 or 17 hr. of fasting. At the same time the serum and milk of the mothers were analysed for lipid components and for free and protein-bound iodine.

In serum, total lipids were about 696 ± 101, cholesterol 163 ± 12·5 and lipid P 11·3 ± 1·0 mg. per cent. for the lactating animals compared with 463 ± 9 for total lipids, 138 ± 8 for cholesterol and 9·6 ± 0·8 for lipid P in the serum of normal adult females. During lactation there was a slow decline in cholesterol and lipid P, but total serum lipid remained high. The level of protein-bound iodine in the serum of the lactating baboon was similar to that of the normal female. In the milk, the mean total lipids increased after the third month of lactation. The milk inorganic iodine and bound iodine fluctuated considerably during lactation, with values as high as 38·0 μg. and 6·9 μg. per cent., respectively.

The sucking baboon reached a post-absorptive state in respect of total lipids and lipid P within 7 hr. after feeding; serum cholesterol was hardly affected, but decreased after prolonged fasting.

(See preceding abst.) G. A. Garton.

4577

KRAFT, H. Gezielte Kalzium-Therapie. [**Rational treatment with calcium.**] *Berl. Münch. tierärztl. Wochenschr.*, 1956, **69,** 168–170. [Med. Tierklin., Univ. Munich.] English summary.

Ca was estimated in the blood and urine of different animals by the method of Kramer and Tisdall. The urine was also tested with the Sulkowitch reagent for Ca. It was concluded that the Sulkowitch test could serve as a check on Ca metabolism or treatment with Ca, except in horses, which have much $CaCO_3$ in the urine.

The Ca content of the urine was no guide to that of the blood. Some values are given for serum Ca in horses, cattle and dogs. Two llamas had 12·1 and 13·08, 3 vicunas 9·48, 13·81 and 17·55, an alpaca 8·97 and a guanaco 12·46 mg. per cent.

HAMILTON, J. B., BUNCH, L. and HIRSCHMAN, A. **Serum inorganic phosphorus levels in males and females at progressive ages, with concomitant measurements of urinary ketosteroids and androgens in man.** *J. Clin. Endocrinol.*, 1956, **16,** 463–472. [Dept. Anat., State Univ. New York Coll. Med., Brooklyn.]

With combined data from 188 human subjects aged from 13 to 85 years and data from Bullock (*Amer. J. Dis. Child.*, 1930, **40,** 724), it was shown that serum inorganic P decreased from birth to sexual maturity and thereafter remained constant. The excretion of androgens and ketosteroids in the urine of 45 men aged from 21 to 75 years decreased with age and was not correlated with serum inorganic P.—A. Hepburn.

4579

CLEGG, R. E., ERICSON, A. T., HEIN, R. E., MCFARLAND, R. H. and LEONARD, G. W. **An electrophoretic component responsible for calcium binding in the blood sera of chickens.** *J. Biol. Chem.*, 1956, **219,** 447–454. [Dept. Chem., Kansas State Coll., Manhattan.]

The electrophoretic pattern of serum from cockerels given diethylstilboestrol in the diet

revealed a fast moving high-phosphorus component which changed its position when Ca was added. When radio-active Ca was added to serum of cockerels non-diffusible radio-active Ca became associated with this component, and it is suggested that the high values for non-diffusible Ca in the serum of laying hens and cockerels treated with stilboestrol are due to the presence of this component.—R. Hill.

4580

RIEDESEL, M. L. and FOLK, G. E. (Jr.) **Serum magnesium changes in hibernation.** *Nature*, 1956, **177,** 668. [Dept. Occupat. Health, Univ. Pittsburgh, Pa.]

Bats of the species *Eptesicus fuscus* were collected while hibernating in a cave and were bled while still dormant or after being kept and fed for 4 days. The others, *Myotis lucifugus*, were caught in a summer colony and during hibernation in a cave, and were bled after from 1 hr. to 9 weeks of hibernation.

Serum K showed no significant change. Serum Ca decreased during hibernation and serum Mg was 50 per cent. above the level in active bats. Sp. gr. of serum rose slightly but not consistently. Serum Mg was high after only 1 to 2 hr. of hibernation and had dropped 1 hr. after the bats were aroused. It was not related to season or closely to body temperature.—D. Duncan.

4581

HOLEMANS, K., ANDRÉ, J. and MARTIN, H. Quelques données élémentaires sur le métabolisme du chlore et de l'eau chez les indigènes du Kwango. **[Metabolism of chloride and water in the native inhabitants of the Kwango.]** *Ann. Soc. belg. Méd. trop.*, 1955, **35,** 591–602. Flemish summary.

In natives of the Kwango, chloride in the blood and plasma was estimated for 43 men, and for 28 non-pregnant and 25 pregnant women. Concentration and amount of chloride and volume of urine excreted in 24 hr. were measured for 51 men and for 51 non-pregnant and 57 pregnant women. The volume of water consumed in 24 hr. was measured for 21 men and 21 adult women and for 31 women at the end of pregnancy. The concentration of chloride in the sweat was estimated for 21 native men and 18 European men.

The mean value for chloride in the plasma was 378·1 mg. per 100 ml., which is 10 mg. higher than that accepted for white subjects. In whole blood the mean for all the native subjects was close to that accepted for white subjects, but the values for native men, women and pregnant women, 291·7, 297·5 and 307·0 mg., respectively, were significantly different from one another and were explained by differences in haematocrit.

The mean concentration of chloride in the urine was less than that recorded in Europe, and in pregnant women it was significantly less than in men and non-pregnant women. The mean volume of urine passed in 24 hr. was less than half that, 1500 ml., accepted for Europeans. That for men was lowest, 569 ml., and that for pregnant women, 747 ml., was highest. The mean amount of chloride in the urine in 24 hr., in g., was 2·92 for men, 3·37 for non-pregnant women and 2·96 for pregnant women ; it was only one-quarter of that reported for white subjects.

The mean volume of water drunk in 24 hr. was 488 ml. for men and non-pregnant women, and 611 for pregnant women, compared with from 1400 to 1500 reported for Europeans in temperate climates, but when allowance was made for the water content of cooked food, particularly for that derived from the native staple, manioc, it was concluded that the intake of water by Europeans and natives was about the same.

The mean concentration of chloride in g. per litre sweat was 2·25 for the 21 natives and 4·16 for the 18 Europeans.

It is calculated that the native consumes only about one-quarter of the salt consumed by the European, for whom the 10 to 15 g. consumed in temperate climates is considered insufficient in the tropics. It is concluded that the African native must have some mechanism for sparing chloride.

E. M. Hume.

4582

GILLES, H. M. and SCOTT, J. G. **Serum iron in Gambian Africans.** *Ann. Trop. Med. Parasitol.*, 1956, **50,** 103–104. [Med. Res. Counc. Labs., Fajara, Gambia.]

Serum Fe was estimated in 31 male and 19 female Gambian Africans attending hospital with minor complaints. They had no anaemia and were apparently free from malaria. The results were closely similar to published values for Europeans: 106 μg. per 100 ml., range 72 to 168, for men, and 98, 74 to 150, for women.—F. E. Hytten.

4583

RECHENBERGER, J. Über die Eisenbindungskapazität des Blutserums. 1. Die Eisenbindungskapazität des Serums bei Hepatitis epidemica und chronischen Leberparenchymschäden. **[Iron-binding capacity of blood serum. 1. Iron-binding capacity of the serum in epidemic hepatitis and chronic damage of liver parenchyma.]** *Deutsch. Ztschr. Verdauungs- u. Stoffwechselkr.*, 1956, **16,** 114–119. [Med. Klin., Univ. Leipzig.]

1. In 86 healthy male subjects in groups between the ages of 10 to 19 and 70 to 79 years, serum Fe and total Fe-binding capacity fell with age [after

age 39 in Table 1]. For men the maximum serum Fe was 128 μg. per cent., at age 30 to 39, and the minimum 80 μg.; corresponding Fe-binding capacities were 328 and 281 μg. For 78 women the corresponding values were 110 and 78 μg.; 328 and 276 μg. Bilirubin, serum Fe and Fe-binding capacity were estimated in 30 patients with epidemic hepatitis. All were above normal; in early stages of the disease, binding capacity seemed more closely related to bilirubin than to serum Fe. In 18 patients with chronically damaged liver parenchyma, after hepatitis, serum Fe was above normal, but Fe-binding capacity was well below normal. The course of events in acute hepatitis may be caused by leakage of Fe, or ferritin and possibly apoferritin, from the damaged liver.

LANZ, H. Über den Eisengehalt des Rinderserums bestimmt nach der kolorimetrischen Eisenrhodanatkomplex-Methode. [**The iron content of cattle serum estimated by the colorimetric iron thiocyanate complex method.**] *Inaugural Dissertation, Vet.-Med. Fac., Univ. Berne*, 1955, pp. 37. [Inst. Tierzucht Hyg., Univ. Berne.]

The work was suggested by the report of von Grünigen *et al.* (Abst. 2667, Vol. 18) on a deficiency disorder of young cattle, cured by giving Fe.

About a third of this mimeographed publication is occupied by a general discussion of iron metabolism, with references chiefly to medical literature, and about a third of the rest by details of methods of estimating Fe in serum. The phenanthroline method as used by Heilmeyer and Plötner (Abst. 5769, Vol. 6) did not give sufficiently accurate or consistent results and a modification of the thiocyanate method (Abst. 140, Vol. 25) of Josephs [wrongly given as Hugh in text and references], in which the colour was measured by the EEL colorimeter with filter 624, was adopted. An accuracy to within ± 4 μg. per cent. is claimed for the procedure.

The following values for serum Fe were obtained, mostly from healthy animals on one large farm near Berne (numbers in brackets): calves for veal, reared on milk only (58), 50 to 116, mean 81·5 μg. per cent.; calves at or after weaning (14), 170 to 234, mean 195·3; fat cattle aged 1½ to 2½ years at slaughterhouse (21), 130 to 228, mean 165, and yearlings and cattle on farm, in good condition after alpine pasture (31), 140 to 204, mean 171; pregnant cows (81), gradual rise from 150 to 204 μg. per cent. during pregnancy, the difference between the means for cows in the first 4 and in the last 5 months being highly significant, and non-pregnant cows (34), 124 to 200, mean 162·4. No relation between serum Fe and milk yield could be established, and little Fe is excreted in the milk; the greatest demand is during pregnancy, to supply the needs of the foetus. It is suggested that tests with readily absorbed forms of Fe should be made on pregnant cows which do not show the rise in serum Fe, to find out whether the serum Fe can be raised or whether they are in Fe equilibrium. The high values for recently weaned calves are interpreted as being due to reaction to a deficit of Fe produced by the diet of milk only, and it is suggested that the disorder described by von Grünigen *et al.* develops because the deficient animals are too weak to digest anything but milk.—W. M. Deans.

DREIZEN, S., GILLEY, E. J., MOSNY, J. J. and SPIES, T. D. **The distribution of selected vitamins in human whole saliva.** *Internat. Ztschr. Vitaminforsch.*, 1955, **26**, 257–262. [Dept. Nutrit. Metabol., Northwestern Univ. Med. Sch., Chicago, Ill.] French and German summaries.

Samples of 25 ml. saliva from 50 subjects were centrifuged at 3000 r.p.m. for 15 min., and vitamin A, vitamin C, pantothenic acid, nicotinic acid and biotin were measured in the supernatant fluid and in the sediment by chemical or microbiological methods. All 5 vitamins were present, and the amounts in the sediment were greater than in the supernatant fluid. The values for nicotinic acid in the two fractions differed significantly. In some subjects large doses of vitamins were given for 7 days, but the amounts found in the saliva did not differ significantly from the original values.

BULMER, M. G. and FORWELL, G. D. **The concentration of sodium in thermal sweat.** *J. Physiol.*, 1956, **132**, 115–122. [R.A.F. Inst. Aviation Med., Farnborough, Hants.]

The hypothesis is advanced that sweat is produced from a precursor fluid with the same Na concentration as interstitial fluid and that the sweat glands absorb Na from the precursor. The amount of Na retained is taken as $b(V + K) - yV$,

where b is the concentration of Na in the interstitial fluid, y that in the sweat, V the rate of sweating and K the amount of water absorbed. At high rates of sweating this is supposed to be constant.

Experiments with young men exercised on a treadmill in a warm environment showed that the hypothesis held for sweat concentrations of more than 50 m. equiv. per litre. Below this concentration Na retention is thought to be less than the maximum. Skin temperature had little or no effect on the Na concentration in sweat.

RAMANATHAN, N. L., GUPTA, A. S. and LUNDGREN, N. P. V. **Changes in the salt concentration of sweat during exercise in monsoon weather.** *Indian J. Med. Res.*, 1956, **44,** 377–384. [Indust. Health Res. Unit, Indian Counc. Med. Res., Calcutta.]

Sweat was collected in small petri dishes from the backs of 6 subjects during exercise on a bicycle ergometer. The sweat was transferred to a cell of 1 mm. bore and the NaCl concentration was calculated in as little as 0·03 ml. from the formula

$$\text{per cent. NaCl} = -0{\cdot}0477 + 47{\cdot}74\,k,$$

where k is the specific conductivity. The salt concentration generally increased progressively with the duration of exercise, usually 90 min. Values obtained agreed with those for larger samples collected in a bag on the arm.

ALLEN, T. H., PENG, M. T., CHEN, K. P., HUANG, T. F., CHANG, C. and FANG, H. S. **Prediction of blood volume and adiposity in man from body weight and cube of height.** *Metabolism*, 1956, **5,** 328–345. [Dept. Physiol., Coll. Phys. Surg., Columbia Univ., New York.]

Blood volume, bodyweight and density were estimated in 81 Chinese men and women. The data were used to find the blood volume of the lean body mass and of the adipose tissue in males and females. Blood volume of the lean body mass was the same, 92·8 ml. per kg., for both sexes, but blood volume of adipose tissue was in males 22·3 and in females 11·7 ml. per kg.

Thus, body mass alone is not a measure of blood volume. An equation relating blood volume to bodyweight and the cube of the height is given for each sex.

A second equation was devised, predicting adiposity from weight and height. The equation was tested on data from several other laboratories and was found to give good predictions.—A. W. Boyne.

4590

ALLEN, T. H., PENG, M. T., CHEN, K. P., HUANG, T. F., CHANG, C. and FANG, H. S. **Prediction of total adiposity from skinfolds and the curvilinear relationship between external and internal adiposity.** *Metabolism*, 1956, **5,** 346–352. [Dept. Physiol., Coll. Phys. Surg., Columbia Univ., New York.]

In 87 subjects skinfold thickness was measured at 10 sites and adiposity was estimated by weighing in water as described in the preceding paper. The average skinfold thickness, less 4 mm. representing the skin itself, was used to predict total adiposity as a percentage of bodyweight. Total adiposity was predicted also from the mass of subcutaneous adiposity, and results by the 2 methods agreed well.

Subcutaneous adiposity was estimated and plotted against internal adiposity, both measured as percentages of lean body mass. The proportion of subcutaneous adiposity to internal adiposity increases with increase in total adiposity.

A. W. Boyne.

ALLEN, T. H., PENG, M. T., CHEN, K. P., HUANG, T. F., CHANG, C. and FANG, H. S. **Similarity of vital capacity in terms of body weight less adiposity in both sexes; appendix on the graphic estimation of adiposity and essential body mass from height and weight.** *Metabolism*, 1956, **5,** 353–358. [Dept. Physiol., Coll. Phys. Surg., Columbia Univ., New York.]

The vital capacity was measured in 87 adults and the essential body mass was calculated from equations which are given. The data were plotted against one another and showed a straight-line relation. A large number of other subjects were included, and showed a mean vital capacity of 93 ml. per kg. essential body mass.

In an appendix 2 charts are given, one for men, boys and girls, the other for adult women, showing the relation between essential body mass on the one hand, and height and weight on the other. These are given as an alternative for the accepted methods of measuring adiposity.—A. W. Boyne.

KOVAL'SKII, V. V. and PADUCHEVA, A. L. Sezonnye izmeneniya obmena veshchestv u karakul'skikh ovetz. [**Seasonal variations in the metabolism of Karakul sheep.**] *Dokl. Akad. Nauk SSSR*, 1956, **106,** 505–507. [Vses. Nauch.-Issled. Inst. Zhivotnovodstva.]

In 118 Karakul sheep the average weight reached its peak of 57·6 kg. in October, then fell gradually to 48·4 kg. in February, went up to 52·0 kg. in April and continued to rise till the next October. The April weight is based on 39 non-pregnant sheep.

The post-partum weight of sheep was 46·4 kg., indicating that the weight gain of pregnant animals was due to the products of pregnancy, the real weight increase of mothers beginning in May.

For blood components maximum values were found in autumn and minimum values in spring. The range per cent. was dry matter 8·1 to 7·1, protein 8·0 to 5·6, Hb 9·5 to 6·5., cholesterol 92 to 45 mg., chlorides 420 to 358 mg., Ca 10·5 to 5·5 mg., and P 9·5 to 3·0 mg.

Skin, muscles and subcutaneous tissues were examined by biopsy from the hindquarters. Chloride content appeared to vary erratically. The water content of muscles was most stable, the dry matter between 20 and 23 per cent. with highest values in summer and autumn and lowest by the end of pregnancy in April. In subcutaneous tissues the dry matter varied between 20 and 34 per cent., lowest in spring and highest in summer. The dry matter content of skin was less stable than that of muscles and was greatest in summer and winter.

The better the nutritional state of the animals, the higher the values for dry matter and its content of protein, Hb, cholesterol and chlorides; poor nutrition leads to hydraemia.—F. Billewicz.

4593

PITTS, G. C. **Body fat accumulation in the guinea pig.** *Amer. J. Physiol.*, 1956, **185,** 41–48. [Dept. Physiol., Sch. Med., Univ. Virginia, Charlottesville.]

The carcases of 72 guineapigs were each separated by dissection into 11 gross body structures, comprising heart, liver, kidneys, spleen, gut, gut contents, brain and spinal cord, muscle, unscraped bone with marrow, skin with subcutaneous fat and internal fat, and a group including all other tissues (lungs, trachea, adrenals, eyes, blood and bile). The guineapigs had been fed to appetite on Purina rabbit chow and fresh greens; 47 were adult animals (26 males and 21 females), 18 growing animals from 4 days to 8 months old (9 males and 9 females), and 7 male animals which had undergone severe exercise from weaning to 8 months of age. The sp. gr. of each eviscerated carcase was estimated and the dissected tissues and organs were freeze-dried and extracted with ether and light petroleum to yield total fat. The distribution of fat and the fat content of each organ and tissue were studied statistically.

The accumulation of fat in each of the groups of rats was associated mainly with the saturation of existing fat depots, though some increase in the number and size of lipocytes took place. Females had a larger fat storage capacity than males without hypertrophy or proliferation of lipocytes. At all levels of body fatness the proportion of total body fat in subcutaneous and internal depots was constant except in immature animals, though males had 6 to 7 per cent. less total fat in the subcutaneous depots and proportionately more in the internal depots than had females. The distribution of fat in the organs was similar in both sexes. In adult animals body fatness was related to sp. gr. of the carcase by the following equation:

$$\text{Fatness} = 100\left(\frac{4{\cdot}183}{\text{sp. gr.}} - 3{\cdot}790\right).$$

About 95 per cent. of total body fat was in the fat depots, most of the remainder in the gut, bone, liver, kidneys and heart.—G. A. Garton.

HRACHOVEC, J. Sur les relations entre les différences des vitesses de croissance des organes et l'évolution de leur teneur en composés lipidiques au cours de la croissance du lapin. [**Relations between differences in rate of growth of organs and changes in content of lipid compounds during growth of the rabbit.**] *C.R. Acad. Sci.*, 1956, **242,** 1071–1074.

Lipid P and free cholesterol were estimated in brain, liver, kidneys, lungs, stomach, muscle and perirenal adipose tissue of rabbits killed between the 19th day of embryonic life and the 620th day of age.

Brain showed a progressive increase in lipid P and free cholesterol content throughout growth to the adult state; similar but smaller increases were found in other tissues, except adipose tissue and muscle. In muscle the maximum content of lipid P was found at 3 weeks of age and the maximum value for free cholesterol at the end of gestation.—G. A. Garton.

4595

YARBRO, C. L. and ANDERSON, C. E. **Acetal phosphatides in the adipose tissue of newborn rats.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 408–409. [Dept. Biochem. Nutrit., Sch. Med., Univ. N. Carolina, Chapel Hill.]

Acetal phospholipins, phospholipins and total lipids were estimated in livers and subcutaneous adipose tissue of young rats killed at 1, 2, 3, 5, 8, 15 and 21 days of age.

The content of acetal phospholipins and total phospholipins in the adipose tissue, which was quite high in animals up to 3 days old, decreased rapidly as depot fat was laid down, until only traces were found in the tissues of rats 3 to 8 days old. Similar changes did not occur in liver lipids. The results indicate that acetal phospholipins and phospholipins are involved in some way in the laying down of depot fat in adipose tissue. A similar process in liver, where lipid turnover is more rapid, is not excluded.—G. A. Garton.

CALÌ, V. Sul comportamento dei lipidi e del glicogeno del fegato e dei muscoli nell'intossicazione subacuta da tetracloruro di carbonio. [**Behaviour of the lipids and glycogen of the liver and muscles in subacute poisoning with carbon tetrachloride.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31,** 948–950. [Ist. Med. Lavoro, Univ. Palermo.]

Of 12 guineapigs weighing from 280 to 345 g., fed on a normal diet, 3 received no treatment, and 9 were exposed to inhalation of CCl_4 vapour for about 5 min. twice daily for 8 days, after which the 7 survivors were killed. In the liver and slightly in the muscles of the poisoned animals, total lipids, fatty acids and the unsaponifiable fraction increased; glycogen decreased.

E. M. Hume.

BERNHARD, K. and LINDLAR, F. Lipidgehalte und Fettsäurezusammensetzung des Gehirns und der Leber ganz junger und alter Ratten. [**Lipid content and fatty acid composition of the brain and liver of young and old rats.**] *Helv. physiol. pharm. Acta*, 1956, **14,** 113–119. [Physiol. Chem. Inst., Univ. Basle.] English summary.

Lipids were extracted from the livers and brains of rats aged 3 days or 22 months and separated into neutral fat and phospholipins. The fatty acids of each fraction were examined spectrophotometrically for their content of polyunsaturated acids; the amounts of palmitic and stearic acids were estimated chromatographically (Abst. 1434, Vol. 26).

The brains and livers of older rats had average lipid contents of 47·9 and 18·2 per cent., on dry matter basis, compared with 24·1 and 23·0 per cent. for the young rats. Brains and livers of the older rats contained 27·5 and 13·2 per cent. phospholipins, those of young rats 17·7 and 7·3 per cent. The relative amounts of polyunsaturated and saturated fatty acids in the different lipid fractions did not show any significant change with age.

HESS, W. C., LEE, C. Y. and PECKHAM, S. C. **The lipide content of enamel and dentin.** *J. Dent. Res.*, 1956, **35,** 273–275. [Dept. Biol. Chem., Sch. Med., Georgetown Univ., Washington, D.C.]

The cholesterol content of human enamel is 0·008 per cent. and that of dentine 0·024 per cent. Total lipids other than cholesterol make up 0·60 and 0·36 per cent., respectively.—A. K. Lough.

4599

ODUM, E. P. and CONNELL, C. E. **Lipid levels in migrating birds.** *Science*, 1956, **123,** 892–894. [Dept. Zool., Univ. Georgia, Athens.]

Specimens of 55 migrating birds, representing 8 species, were obtained in Georgia, U.S. The carcases were frozen and then minced before extraction of total lipids. The lipid content of these birds was compared with that of birds before and after their migration and also with that of several non-migratory birds.

The migrating birds, in passage to Central or South America, had a lipid content of about one-third of their dead weight or about two-thirds of their dry weight; this lipid was mostly in large subcutaneous and intraperitoneal depots. By contrast, resident species and migratory species when not engaged in migration contained much smaller amounts of lipid. Just before migration all organs, except the heart, increased in lipid content.

G. A. Garton.

THACKER, E. J., ALDERMAN, M. L. and BRATTON, R. W. **The effect of plane of nutrition on the mineral composition of blood serum, liver, and on the growth of bone.** *J. Animal Sci.*, 1956, **15,** 447–455. [U.S. Plant, Soil Nutrit. Lab., A.R.S., Ithaca, N.Y.]

Holstein bull calves were fed from 3 days old on low, medium or high planes of nutrition with balanced rations. Some calves were slaughtered at 16, 32, 48, 64 and 80 weeks of age.

The composition of bone was not affected by the plane of nutrition, and was the same in calves of the same weight. Up to 80 weeks of age skeletal growth continued normally on all planes of nutrition.

Blood serum Cu, Mo and Mn were not affected by age. Serum Cu increased with rising plane of nutrition.

In liver, water content decreased with age, but there was no difference with plane of nutrition. Iron, Mo and Mn were not affected by the conditions studied. Up to 48 weeks the Cu concentration of the liver decreased; it then remained constant, and was greater on the high than on the lower planes of nutrition.—T. D. Bell.

FORBES, G. B., REID, A. F., BONDURANT, J. and ETHERIDGE, J. **Changes in total body chloride during growth.** *Pediatrics*, 1956, **17,** 334–340. [Dept. Paediat., Sch. Med. Dent., Univ. Rochester, N.Y.] Spanish and Interlingua summaries.

Data on total body chloride in foetuses were obtained from the literature. The authors' own data, obtained by dilution studies with radio-active Br, for infants (Title 1522, Vol. 24) and for adults (Reid *et al.*, to be published) were used also. The data conformed to the differential growth equation $y = bx^k$, where y is total body Cl, x is bodyweight,

log b is the intercept on the y axis and k is the slope. Chloride content is thus a simple power function of bodyweight.—F. C. Aitken.

4602

BECK, A. B. **The copper content of the liver and blood of some vertebrates.** *Austral. J. Zool.*, 1956, **4,** 1–18. [Div. Animal Health Prod., C.S.I.R.O., Lab. Animal Health Nutrit., Dept. Agric., Nedlands.]

Cu was estimated with diethyldithiocarbamate complex in amyl alcohol after destruction of the organic matter with nitric, sulphuric and perchloric acids. Values for liver and blood are given in appendix tables. Livers were obtained from domestic and wild species of mammals, birds, reptiles, amphibians and fish and blood samples from some of the species.—D. Duncan.

WEITZEL, G., BUDDECKE, E., FRETZDORFF, A. M., STRECKER, F. J. and ROESTER, U. Zink im Augenhintergrund des Seehundes. [**Zinc in the fundus of the seal.**] *Hoppe-Seyler's Ztschr.*, 1956, **304,** 1–10. [Biochem. Abt., Med. Forschungsanst., Max-Planck-Gesellsch., Göttingen.] English summary.

Previous work (Title 861, Vol. 24; Abst. 659, Vol. 25; *Hoppe-Seyler's Ztschr.*, 1955, **299,** 193) had shown that the tapetum lucidum of the eye of carnivores was exceptionally rich in Zn and S, present as a complex of Zn and cysteine. In the present paper Zn was again estimated polarographically (Title 119, Vol. 24) and by a complexometric method (Flaschka, *Mikrochemie*, 1952, **39,** 38) and S by the method of Fritz and Freeland (*Anal. Chem.*, 1954, **26,** 1593), and Zn and cysteine were detected by paper chromatography as before in different parts of 200 eyes of seals (*Phoca vitulina*, L.) killed on the west coast of Schleswig-Holstein in summer.

The amounts of Zn found in lens, vitreous humour, retina and iris were trifling. In contrast, very large amounts were found in the choroid, almost all in the relatively abundant tapetum lucidum, which contained from 20 to 30 mg. per g. fresh tissue, or about 10 mg. per eye, in adult seals; young animals, 10 weeks old, had much less. There was roughly half as much S as Zn. Further study showed that again Zn was present as a Zn-cysteine complex, which formed 60 per cent. of the dry matter of the tapetum, the rest being the usual cell constituents; no cystine or other organic compound linked with Zn was detected.

DISCHE, Z., BORENFREUND, E. and ZELMENIS, G. **Changes in lens proteins of rats during aging.** *Arch. Ophthalmol.*, 1956, **55,** 471–483. [Dept. Ophthalmol., Coll. Phys. Surg., Columbia Univ., New York.]

The wet weight of the rat lens increased rapidly from 20 mg. at 35 days old to 54 mg. at 300 days. From then until 151 weeks old the rise was very slow. Total lens protein also increased rapidly from 7·5 mg. to about 18 mg. at 20 weeks old and then more slowly to reach a maximum of about 27 mg. Soluble protein, starting at about 7 mg. was almost doubled at 20 weeks old, reached a maximum of about 15 mg. at a year and then fell to about 12 mg. The insoluble protein of the lens increased at a declining rate from less than 1 mg. to about 15 mg.

The soluble proteins did not contain significant amounts of cystine, but the insoluble proteins contained as much cystine as cysteine. The amount of cystine plus cysteine was about 2·4 per cent. in both proteins in rats under 20 weeks old. In soluble proteins it decreased with age to 1·2 per cent. but it was fairly constant in the insoluble proteins. There were more SH groups available for oxidation by ferricyanide in young than in older rats.—A. Hepburn.

BATTISTONE, G. C. and BURNETT, G. W. **Studies of the composition of teeth. 3. The amino acid composition of human dentinal protein. 4. The amino acid composition of human enamel protein. 5. Variations in the amino acid composition of dentin and enamel.** *J. Dent. Res.*, 1956, **35,** 255–259; 260–262; 263–272. [Dept. Dent. Res., Army Med. Serv. Grad. Sch., Walter Reed Army Med. Centre, Washington, D.C.]

3. Dentine was separated by a flotation method from caries-free permanent teeth recently extracted from men over 18 years of age. Decalcification was by ethylenediamine tetra-acetic acid (EDTA) solution, *p*H 7·0 to 7·5, or the dentine protein was extracted by refluxing with distilled water. After hydrolysis by acid, amino acids were separated and estimated chromatographically. The findings for 16 acids are tabulated and, by comparison with Neuman's results (Abst. 533, Vol. 20) the organic matrix of dentine is concluded to be a collagen.

4. Enamel was separated by chipping from teeth from sources as in Part 3 and amino acids were estimated after decalcification with EDTA. The histidine : lysine : arginine ratio, 1 : 4 : 12, was

that of a eukeratin, but the presence of proline and hydroxyproline and the high and low contents, respectively, of glycine and cystine suggested that the protein was not a typical keratin.

5. Six tables are presented to show the amino acid composition of dentine and enamel from non-carious human teeth and to illustrate the effect on that of preserving the teeth for several months, of separating the dentine and enamel by flotation or by chipping and of decalcifying with EDTA, HCl, Morse solution or lactic acid. In preserved teeth there was less proline, total amino acid and N than in freshly extracted teeth. The effect of method of preparation was slight on dentine, but in enamel by the flotation method there was less glutamic and aspartic acids and more ash than by the chipping method. Some losses of amino acids from both dentine and enamel occurred with each decalcifying fluid, least with EDTA.—D. Harvey.

DUCTLESS GLANDS AND HORMONES

4608

GODING, J. R. and DENTON, D. A. **Adrenal cortex and the parotid secretion of sodium-depleted sheep.** *Science*, 1956, **123,** 986–987. [Ionic Res. Unit, Dept. Physiol., Univ. Melbourne.]

Sheep with a fistula of the parotid duct rapidly become depleted of Na if not given extra Na to replace losses. When deoxycorticosterone was given to a sheep moderately depleted of Na in this way, the Na content of the saliva fell and the K content rose; but when the sheep was grossly depleted of Na, deoxycorticosterone had little effect on the saliva.

Sheep with a parotid fistula had both adrenals removed. They could be kept in good condition with 5 to 10 mg. deoxycorticosterone and 25 mg. cortisone daily when enough Na was given also. When the hormones were withdrawn there was the expected large loss of Na in urine and fall in the plasma Na : K ratio, but an increase in the Na : K ratio of saliva. When deoxycorticosterone was increased to 40 mg. daily the Na : K ratio of saliva fell in 5 days from 17 to 2. When Na was withheld, there was little change in the ratio, but signs of adrenal insufficiency appeared in 2 to 4 days. When Na was withheld, but deoxycorticosterone was raised to 20 mg. daily, salivary Na : K ratio fell as it did in sheep with adrenals intact.

It is considered that the adrenal is concerned in the response of the parotid to Na depletion.

BRUNNER, H., KUSCHINSKY, G. and PETERS, G. Die Beeinflussung der renalen Wasser- und Salzausscheidung normaler und hypophysektomierter Ratten durch Nebennierenrindenhormone. [**Effect of adrenal cortical hormone on renal excretion of water and salt in normal and hypophysectomised rats.**] *Arch. exp. Pathol. Pharmakol.*, 1956, **228,** 578–595. [Pharmakol. Inst., Univ. Mainz.] English summary.

4610

BOIS, P. and SELYE, H. **Inhibition by food restriction of the renal damage due to corticoid-overdosage.** *Experientia*, 1956, **12,** 144–146. [Inst. Med., Univ. Montreal.] German summary.

Five groups, each of 10 rats from which one kidney had been removed, were given 1 per cent. NaCl solution to drink. One group on unrestricted diet served as controls; the 4 other groups were given subcutaneously 1 mg. deoxycorticosterone acetate (DOCA) alone or with 1 mg. cortisol acetate (COLA), 2 groups with diet unrestricted and 2 with diet restricted so as to cause loss of bodyweight of from 1/5 to 1/4 of its initial amount. At the beginning average bodyweight was 99 g. The animals were killed after treatment for 20 days.

Control rats gained weight and showed no nephrosclerosis or myocarditis. With unrestricted diet and DOCA alone bodyweight increased, kidney and heart were much enlarged, nephrosclerosis and myocarditis were present and fluid intake was high; with DOCA and COLA there was slight loss of weight, fluid intake and myocarditis were not altered and nephrosclerosis was aggravated. With restricted diet and DOCA alone loss of weight was 20 per cent. and no cardiac or renal lesion appeared; with DOCA and COLA loss of weight was 27 per cent., nephrosclerosis and myocarditis appeared, weights of kidney and heart and amount of fluid drunk were greater than with DOCA alone, but less than with unrestricted diet.

Reduction of food intake by drugs or other experimental conditions will, it is concluded, inhibit the production of nephrosclerosis by corticoids.—D. Harvey.

GILSANZ, V., PAPACIOS, J. M., MEDINA, E. and HUECK, A. La prueba de la sobrecarga de calcio en el hipoparatiroidismo y otros procesos. [**The test of calcium tolerance in parathyroid insufficiency and other disorders.**] *Rev. clín. española*, 1956, **60,** 360–365. [Clín. Méd., Univ. Madrid.] English, German and French summaries.]

The calcium load test of Howard *et al.* (Title 3250, Vol. 23), in which subjects received intravenously 15 mg. Ca ions per kg. bodyweight, was made on 8 patients with different disorders and 1 normal subject. Values for Ca and P in serum and urine before and at intervals after the infusion are tabulated.

In the normal subject and in the 2 patients with mammary cancer, one with chronic Pb poisoning, one with poikiloderma and one with scleroderma, the infusion of Ca caused a rise in serum Ca, increased output of Ca in the urine, high serum P and low urinary P. Similar results were found in one patient with post-operative parathyroid insufficiency, but in another with the same condition the urinary P output increased and serum P was almost unchanged, and there was a particularly sharp rise in serum Ca, initially low. The test is thus of uncertain value in the diagnosis of parathyroid insufficiency. The ninth subject, with multiple sarcoma and many skeletal lesions, showed elevated serum P as well as increased urinary P, and the result was difficult to interpret.

MARTMER, E. E., CORRIGAN, K. E., CHARBENEAU, H. P. and SOSIN, A. **A study of the uptake of iodine (I-131) by the thyroid of premature infants.** *Pediatrics*, 1956, **17,** 503–509. [Div. Paediat., Harper Hosp., Detroit, Mich.] Spanish and Interlingua summaries.

The uptake of ^{131}I by the thyroid, 24 hr. after administration of 5 μC. ^{131}I by mouth or by stomach tube, was measured with Geiger Müller and scintillation counters in 65 premature and 5 term infants, aged 1 to 63 days.

The range of uptake was within the normal limits recorded with the Geiger Müller counter in studies of children and adults. The scintillation counter is described. After experience with this equipment was acquired the difference in results obtained by the 2 methods was less than 5 per cent.

RIVERO-FONTAN, J. L. Influencia de la hiponutrición sobre el tiroides de ratas. [**Influence of undernutrition on the thyroid of rats.**] *Rev. española Enferm. Apar. digest. Nutrición*, 1956, **15,** 239–248. [Clín. Méd., Univ. Seville.] English summary.

Rats of both sexes received for a week a diet containing, per cent., glucose 72, casein 16, lard 8 and mineral mixture 4 and vitamins. Their intake was measured. They were then divided into 3 groups of 23, 20 and 19. One group continued on this diet to appetite, a second had a quarter of their intake during the preliminary week. The third group received a quarter of the energy value, but it was given as a diet containing 64 per cent. casein and 24 per cent. glucose, so that their protein intake was maintained. All the rats had distilled water to drink and were given KI intraperitoneally to ensure an equal I intake. All were killed after 16 days, and 4 hr. before death each received 4 μC. ^{131}I as KI intraperitoneally.

The rats fed to appetite gained weight. The underfed rats on both diets lost between 30 and 34 per cent. of their initial weight. The mean absolute weight of the thyroid in male and female rats, respectively, was in rats fed to appetite 12·26 and 12·25 mg., in those deprived of energy and protein 7·67 and 3·75 and in those with low energy and normal protein intake 7·74 and 3·52 mg. Uptake of ^{131}I by the thyroid, in counts per mg. tissue, was reduced in all the deprived groups, though in female rats with low energy and normal protein intake the fall was not significant. The histological picture of the thyroid in underfed rats showed reduced activity.

It is concluded that protein deficiency did not influence the effect of general undernutrition in the rats.—D. Duncan.

FRIEDBERG, W. and REINEKE, E. P. **Metabolism of iodinated casein in the rat.** *Amer. J. Physiol.*, 1956, **185,** 27–30. [Dept. Physiol. Pharmacol., Michigan State Univ., East Lansing.]

About 2 mg. radio-active iodinated casein was injected into the femoral vein of each of 10 female albino rats of average weight 168 g. After 100 min. 1 to 3 ml. blood was taken from the vein on the opposite side and dried and radio-activity was measured. Tissues were treated in a similar way.

The highest concentration of radio-activity was found in the liver, which showed a concentration 5·65 times that in plasma. The next highest was in spleen and then kidney, stomach, lung, small intestine and large intestine in that order. The lowest concentration was in muscle.

Eight female rats of weight 230 g. had thyroid and parathyroids removed and were treated with Ca to prevent tetany ; 10 mg. radio-active iodinated casein was injected intravenously. Blood from the aorta and liver samples were taken from 2 rats after 1½, 24 and 72 hr. Plasma and liver samples were separated into free thyroxine-like compounds and combined thyroxine-like compounds and the radio-activity was measured.

Within 1½ hr. both compounds were found in plasma and liver. At 24 and 72 hr. the combined thyroxine-like compounds had disappeared from the plasma and were concentrated in the liver. Simultaneously there was a pronounced increase of free thyroxine-like compounds in the plasma. This seemed to indicate that the liver was the principal site for the liberation of thyroxine from iodinated casein.—B. W. Simpson.

ZOFFMAN, A. Regulación endocrina de las proteínas del plasma. Influencia de la hipofisis. [**Endocrine regulation of the plasma proteins. Influence of the pituitary.**] *Rev. española Enferm. Apar. digest. Nutrición*, 1956, **15**, 300–308. [Clín. Méd., Univ. Seville.] English summary.

The literature is reviewed. Serum proteins were studied in 2 patients; they were normal in one with pituitary cachexia, and the albumin : globulin ration was high in one with Cushing's syndrome.—D. Duncan.

4616

BAKER, B. (Jr.), HOLLANDBECK, R., NORTON, H. W. and NALBANDOV, A. V. **Growth hormone content of swine pituitaries in relation to growth rate and age.** *J. Animal Sci.*, 1956, **15**, 407–417. [Dept. Animal Sci., Univ. Illinois, Urbana.]

Immature female hypophysectomised rats were used to estimate the growth hormone content of anterior pituitary glands from 65 female Hampshire and Duroc pigs. The pigs represented all ages, foetal, immature, mature and pregnant, up to a liveweight of 600 lb. and 1400 days of age. Composition of carcase and length of femur and tibia of immature and mature animals were estimated.

Percentage of dry matter, ether extract, N and bone ash increased with age up to 1400 days : the increase was rapid up to 300 days, and then slower. Up to 300 days femur and tibia increased rapidly in length, and after 300 days growth continued slowly up to 1400 days.

The weight of the anterior pituitary increased rapidly up to 225 days, and then slowly. The ratio of pituitary weight to bodyweight decreased quickly up to 225 to 300 days, and then remained constant. The growth hormone potency of a given weight of pituitary was significantly less in pigs under 20 days of age than in older animals, and total hormone content was low in the foetal gland and increased constantly. When hormone available per unit liveweight was calculated it was high in foetal and immature animals, and decreased to 225 days, after which it remained constant. Neither breed nor pregnancy appeared to affect the potency of the tissue or availability of the hormone.—T. D. Bell.

4617

GREENBAUM, A. L. **The short-term effect of pituitary growth hormone on the catabolism of fat in the liver.** *Biochem. J.*, 1956, **63**, 159–163. [Dept. Biochem., University Coll., London.]

Female rats, normal or rendered diabetic by injection of alloxan, were given intraperitoneal injections of pituitary growth hormone and were killed either 6 or 12 hr. later. The capacity of liver tissue to oxidise octanoate was investigated as described by Greenbaum and McLean (Abst. 4655, Vol. 23).

Six hours after injection of growth hormone liver tissue of normal rats showed diminished ability to oxidise octanoate; this was not found in similarly treated diabetic rats. Twelve hours after injection of growth hormone, oxidation of fatty acid to 2-carbon fragments, CO_2 and H_2O increased; diabetic rats showed increased oxidation of octanoate to 2-carbon fragments, but no increase in further oxidation.

It is suggested that, in normal animals, the impaired ability to oxidise octanoate 6 hr. after injection of growth hormone is not a direct effect, but is brought about by an effect of the hormone on the pancreas, resulting in release of insulin.

WILGRAM, G. F., BEST, C. H. and BLUMENSTEIN, J. **Effect of growth hormone and testosterone on induction of cardiovascular changes in choline-deficient rats.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91**, 620–622. [Banting and Best Dept. Med. Res., Univ. Toronto, Canada.]

In preliminary investigations which confirmed the findings of Hall and Bieri (Abst. 3362, Vol. 24), the ideal bodyweight of rats to be given the choline-deficient diet was found to be between 110 and 115 g. The experiment reported was with female rats of that size and on the deficient diet, of which 7 were given subcutaneously 3 mg. growth hormone daily, 9 testosterone 1 mg. daily and 11 both hormones; a control group of 18 were given injections of saline. Injections were given for 14 days at most; survivors were kept on the diet for a further 3 weeks, after which they and the control animals were killed.

All control rats had fatty livers, but the incidence of kidney and heart lesions was low. Of those given growth hormone, more than half died of renal cortical necrosis, and at least half of the aortae showed the type of lesion described in Abst. 3240, Vol. 23. In the rats given testosterone the

lesions were similar but less advanced ; in those given both hormones they were more severe in degree, but no more frequent.

It is concluded that in choline deficiency the etiology of cardiovascular lesions is closely associated with kidney damage, but a causal relation could not be established.—D. Harvey.

PALA, A. Influenza dell'ormone somatotropo (STH) e dell'ormone androgeno sulle cartilagini articolari e di coniugazione nel ratto. [**Influence of growth hormone and of the male sex hormone on articular and metaphyseal cartilages in the rat.**] *Rend. Ist. Super. Sanità, Rome*, 1956, **19,** 253–282. French, English and German summaries.

The 16 rats, weighing initially 90 to 92 g., were divided into 4 groups of 4 animals and studied for 75 days. All were fed on stock diet. Four rats received lyophilised growth hormone subcutaneously, 1 mg. daily for 20 days, then 2 mg. daily for 20 days, 4 mg. daily for 10 days and 6 mg. daily for the last 15 days. A second group received daily for the whole 75 days 2 mg. testosterone propionate subcutaneously, a third group both hormones and the fourth group none. All rats were weighed and their body length was measured weekly. At the end X-ray photographs were made and the rats were killed for macroscopic and histological examination. The 2 rats which died after 30 and 35 days of treatment with both hormones were examined in the same way as the others.

The rats treated with growth hormone alone or in combination with testosterone showed irregularity of the articular cartilages of the knee joint and an increase in width of the transparent metaphyseal bands in the femur and tibia. Changes in the vertebral column were less apparent in X-ray photographs, but in the rats given both hormones there seemed to be some decalcification of the vertebral bodies. The histological changes in the cartilages are fully described ; there was hypertrophy, interrupted on articular surfaces by areas of erosion. Testosterone did not in general modify the effects of growth hormone, but sometimes seemed to increase them.

The animals appeared clinically healthy, except that those given both hormones were dull and aggressive and their coats were rough after 2 or 3 weeks. The total gain of weight in 75 days was identical in controls and rats given one hormone, though the curves of growth differed ; rats given both hormones gained only half as much. Growth in length was reduced in rats given testosterone.

Rats treated with growth hormone had smaller pituitaries and testes and larger adrenals than untreated rats. Those given testosterone showed only slight differences from controls. The 2 rats given both hormones for 75 days had small pituitaries, testes larger than those of rats given growth hormone alone, and large adrenals.

The significance of the findings is discussed. There are 44 photographs illustrating the radiological and histological findings.—D. Duncan.

GERTNER, M. L. and SZEGEDI, B. Adatok a zsírbeépítés neurohumorális mechanizmusához. [**Neurohumoral regulation of fat deposition.**] *Rep. Fac. Animal Husb., Hung. Univ. Agric. Sci.*, 1955, **1,** No. 10, 17–27. [Inst. Physiol., Univ. Agric. Sci., Budapest.] Russian, German and English summaries.

Fattening in animals is considered as a pathological process, causing compensating mechanisms controlled by the hypothalamus to come into operation. The compensation is seen in the decreased appetite, poorer utilisation of feed and increased basal metabolism of the fat animal.

Lean and moderately fat pigs weighing 110 to 220 kg. had normal blood ketone levels of about 1·613 mg. acetone per cent. In pigs of 350 kg. the value was 2·94 mg. per cent., and in a very fat Berkshire weighing 400 kg., 4·05 mg. The rising ketone level suggests increasing mobilisation of depot fat. A ketogenic hormone prepared from the anterior pituitary was injected into rabbits and raised the mean blood ketone level from 2·5 to nearly 7·5 mg. per cent. in 2 hr. It is concluded that there is a relation between the production of pituitary ketogenic hormone and the fattening tendency in animals. It is hoped that an antagonist to the hormone might improve the utilisation of feed by fattening pigs. (From English summary.)—D. Duncan.

RAMACHANDRAN, M., VENKATACHALAM, P. S. and GOPALAN, C. **Urinary excretion of 17-ketosteroids in normal and undernourished subjects.** *Indian J. Med. Res.*, 1956, **44,** 227–230. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor, S. India.]

The output of 17-ketosteroids in the urine in 24 hr. by 9 normal Indian men ranged from 3 to 13 mg., average 7·94, and by 12 normal Indian children from 0·06 to 1·80 mg., average 0·41. Five children aged 3 to 12 years, who had kwashiorkor, excreted 0·09 to 0·78 mg. daily, average 0·29, but more normal amounts after several weeks on a diet rich in protein. Six men with nutritional oedema excreted 0·2 to 0·89 mg. daily, average 1·05, and even after 89 days on high-protein diet values were still considerably below normal.

KOKAS, E., MICZBÁN, I. and TÖRŐ, I. **Effect of purine nucleotides on working capacity, on the heart and the suprarenal gland.**

BANGA, I., KOKAS, E., MICZBÁN, I. and TÖRŐ, I. **Action of purine nucleotides on the nucleic acid content of the heart during exercise.** *Acta physiol. hung.*, 1955, **7**, 409–420; 401–407. [Inst. Histol. Embryol., Med. Univ., Budapest.] Russian summary.

(a) There were 4 groups, 91 adult rats in all. They received subcutaneous injections daily of physiological saline, corhormone (extract of embryonic heart), adenosine triphosphate (ATP) or a guanylic acid derivative (GAD) isolated from corhormone by Kokas and Banga (*Acta physiol. hung.*, 1950, *Suppl.* **1**, 24). After 2 weeks 9 or 10 rats from each group were made to swim until exhausted every day and the others were not exercised. This continued for 4 weeks, and rats were killed after 12 to 14, 17 to 19 and 22 to 24 days.

Swimming performance, *i.e.*, the time for which the rats could swim, despite a lead weight, before they sank, was progressively improved by corhormone, by ATP and especially by GAD. By the end the untreated rats were still able to swim for about 2 min., those given GAD for nearly 12 min.

At the end the untreated and exercised rats had enlarged hearts compared with those of unexercised animals. Rats given corhormone or ATP also had some enlargement of their hearts, but GAD had prevented enlargement of the heart in exercised rats. The adrenals were also greatly enlarged in exercised rats given saline, slightly enlarged in those given corhormone, but almost or completely normal in size in rats given ATP or GAD.

The effects of GAD in improving performance and preventing hypertrophy of heart and adrenals were statistically significant. It is concluded that GAD is one of the active substances in corhormone.

(b) The nucleic acid P content of the heart was examined in rats treated as described above.

In rats given saline injections the nucleic acid P content of heart tissue was reduced by exercise, but it was normal or increased in exercised rats treated with ATP, corhormone or GAD. There was no effect of the hormones in rats not exercised.

CAREN, R. and CARBO, L. **Pancreatic alpha-cell function in relation to cholesterol metabolism.** *J. Clin. Endocrinol.*, 1956, **16**, 507–516. [Inst. Med. Res., Div. Labs., Cedars of Lebanon Hosp., Los Angeles, Calif.]

In rabbits $CoCl_2$ given intravenously produced a large increase in plasma cholesterol, with a peak after 2 to 3 days and return to normal after 7 days. With this rise and fall there was corresponding destruction and regeneration of alpha cells of the pancreas. Other explanations of the rise in plasma cholesterol were eliminated and it is suggested that the alpha cells may secrete a hormone regulating cholesterol metabolism.—A. Hepburn.

BENGTSSON, E. **The working capacity in normal children, evaluated by submaximal exercise on the bicycle ergometer and compared with adults.** *Acta med. scand.*, 1956, **154**, 91–109. [Contagious Dis. Hosp., Stockholm.]

The subjects were 37 boys and 39 girls between the ages of 5 and 14 years, 7 boys and 7 girls between 15 and 20, and 12 men and 12 women between 31 and 40. The adults were mostly professional and not active in athletics; few were manual workers. The equipment and methods of study were modifications of those of Wahlund

(*Acta med. scand.*, 1948, *Suppl.* 215). For most subjects loads were adjusted to 3 grades, the first to increase heart rate to between 125 and 130, the second to between 140 and 150 and the third to between 160 and 170 beats per min. Work at each loading lasted 6 min.

For both children and adults the relation of heart rate to intensity of exercise was linear up to the highest of these rates. At rates above 170 beats, when they were tested, the subjects had difficulty in continuing the exercise. Working capacity in adults was about 30 per cent. higher in men than in women, a highly significant difference; in children there was no significant difference between sexes. Variations with age were small among adults; in comparisons among children those from 5 to 6, 7 to 9, and 10 to 11 years had working capacities 37, 50 and 83 per cent., respectively, of that of a child of from 13 to 14 years and 20, 28 and 44 per cent. of that of an adult man.

In relation to bodyweight, children in the 4 groups 17 to 24, 25 to 28, 29 to 39 and 40 to 60 kg. had similar working capacities, and these were consistent with the age groupings 5 to 6, 7 to 9, 10 to 12 and 13 to 14 years. Among children, too, the correlation between intensity of work and bodyweight, surface area or age was highly significant. For subjects between 15 and 20 numbers were small and results generally unreliable. Among adults coefficients of correlation were still lower, except for women, for whom bodyweight and surface area were well correlated with working capacity.

Pulse rate was recorded when it was steady with the highest load and again immediately and 4 and 10 min. after exercise. Correlation values were low and no estimate of working capacity could be based on pulse rate during recovery. Respiration rate, respiratory minute volume and oxygen consumption increased linearly with intensity of exercise.

The findings are discussed, and are to be a basis for an investigation of patients with myocarditis.

D. Harvey.

4629

HOLLMANN, W., MUKERJI, G. S. and SPIEGELHOFF, W. Stoffwechsel, Atmung und Kreislauf bei Yogaübungen. [**Metabolism, respiration and circulation during Yoga exercises.**] *Deutsch. med. Wochenschr.*, 1956, **81,** 675–676. [Med. Klin., Univ. Cologne.]

The oxygen consumption of one of the authors, a Yoga teacher, measured with the Knipping spirometer, was 290 c.c. per min. at rest, and during performance of 12 different Yoga exercises, each of which consists in holding a prescribed pose for ½ to 2 min. and ½ to 2 min. rest in the "dead man" position, ranged from 300 to 590 c.c. per min. Only 2 of the poses involved oxygen debt. The cost of the Yoga sleep position, breathing exercises and profound meditation did not differ from that of rest.—W. M. Deans.

4630

CARLSON, L. D. and PEARL, D. C. (Jr.) **Effects of temperature and work on metabolism and heat loss in man.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 240–244. [Dept. Physiol. Biophys., Sch. Med., Univ. Washington, Seattle.]

Skin temperature, loss of heat and oxygen consumption were measured in 4 men. Experiments began at an ambient temperature of 20° C., which was decreased in ½ hr. to 10° C. and maintained there for 30 to 60 min. The subjects wore shorts. Exercise on a bicycle ergometer at 150 or 70 kg. metres per min. was begun either at the start of cooling or when shivering began.

When exercise began early the skin temperature dropped faster in the first 30 min. than when the subject was at rest, but the final skin temperature was slightly higher. Oxygen consumption during exercise was similar at 20° C. and during cooling. Rectal temperature was maintained when there was exercise, but fell slightly during cooling at rest. When exercise began after cooling, heat input was greater and heat loss from the legs was less. Falls in skin and rectal temperature were arrested, but skin temperature did not rise. After 90 min. of shivering, exercise which at 20° C. required 45 kg. cal. per hr. per sq. m. required an extra 76 kg. cal. and even then did not stop shivering in 30 min.

It is concluded that the energy cost of exercise is greater after than during cooling, though the direct heat loss is less.—D. Duncan.

4631

SAPIN-JALOUSTRE, J. and SAPIN-JALOUSTRE, H. Le ralentissement de la vitesse de croissance des phanères dans l'Antarctique. [**Slowing down of the rate of growth of hair, beard and nails in the Antarctic.**] *Presse méd.*, 1956, **64,** 901–903.

Mean growth of the left thumbnail for 4 men in well heated winter quarters (7° to 14° C. at 1·5 m. above the floor) in Adélie Land was 0·102 mm. between June and November (*i.e.*, spring), about three-fifths of that given by Giroud and Bulliard (*Arch. Morph. Gén. Exp.*, 1930, p. 1) for France. Growth of the hair and beard in 2 of the men was similarly reduced relative to the results of Derobert and Lebreton (*Ann. Méd. Lég.*, 1951, **31,** 173) for France and to those for one of the subjects during the return voyage. The much greater reduction

found by Maclean during the Australian Antarctic Expedition of 1911–14 (*Sci. Rep.*, Vol. 7, Series C, 1919) is considered to have been due to the severer conditions (air temperature near 0° C., walls below); in the present expedition the retardation, though not measured exactly, was much greater during establishment of the base in summer with constant exposure to temperatures from 0° to 15° C. and sleeping in unheated tents. The phenomenon is considered to reveal diminished metabolism of the superficial regions of the body and it is believed that permanent reduction of the temperature of the outer layer of the body plays an essential part in acclimatisation to cold.—W. M. Deans.

ALIM, K. A. and AHMED, I. A. **Effects of climate on body temperature and respiration-rate of buffaloes and Friesian cattle.** *Nature*, 1956, **177**, 900. [Dept. Animal Prod., Fac. Agric., Univ. Alexandria.]

Rectal temperature and respiration rate were measured 3 times a day twice weekly for 7 weeks in 2 Friesian and 2 buffalo cows in the early stages of their first lactation, and 2 buffalo, 2 native and 2 Friesian bull calves. All were kept in open sheds, and the air temperatures, recorded at the same time as the other observations, were between 37·2° and 38·9° C.

There were significant differences between body temperatures and respiration rates on different days and at different times of the day.

Buffaloes had lower average body temperatures and respiration rates than Friesian or native cattle, and native calves lower than Friesian. In buffaloes significant positive correlations were found between air and body temperatures and respiration rates, but not between air temperature and body temperature.—T. D. Bell.

EYAL, E. **The body temperature and cardio-respiratory activities of shorn and unshorn Awassi sheep.** *Bull. Res. Counc. Israel*, 1954, **4**, No. 3. [Dept. Animal Husb., Agric. Res. Stat., Rehovot.]

In an investigation with 20 Awassi milking sheep it was shown that shorn animals had lower rectal temperatures than unshorn, except in summer when exposed to strong sunlight. Records were made at 5 a.m., 9 a.m., 2 p.m., 7 p.m. and midnight; environmental temperature ranged from 11·0° in early morning to 32·5° C. at midday between December 1952 and October 1953. During the autumn it was particularly apparent that the rise in body temperature of the shorn sheep to midday, and the decline thereafter, were much more rapid than that of the unshorn.

The changes in respiration rate showed more striking differences between shorn and unshorn sheep. In the shade in both winter and summer, respiration of the shorn sheep was slower; in summer sun it was faster, and the fall in environmental temperature after noon caused a more rapid fall in respiration rate in the unshorn animals.

Results concerning pulse rate were not sufficiently clear for comparison between shorn and unshorn sheep, but in both groups the pulse was faster and less stable in winter than in summer; this may have been related to the higher metabolic rate during the main milking season.

T. D. Bell.

4636

ERIKSON, H. **Observations on the metabolism of Arctic ground squirrels (Citellus Parryi) at different environmental temperatures. Body temperature of Arctic ground squirrels (Citellus Parryi) at varying environmental temperature. Observations of the body temperature of Arctic ground squirrels (Citellus Parryi) during hibernation.** *Acta physiol. scand.*, 1956, **36**, 66–74; 75–78; 79–81. [Inst. Resp. Physiol., Univ. Oslo.]

(a) Six Arctic ground squirrels were kept in an outdoor cage in Alaska and fed on grain, lettuce, cabbage and meat. They were studied in August, when they were active and gaining weight. Oxygen uptake and carbon dioxide output were studied in an open-circuit system which is described and illustrated.

The squirrels could remain in the cold room at − 30° C. for 24 hr. without ill effect. When metabolic rate was studied in the cold the squirrels were so active that the temperature in the cage did not fall below − 19° C. In 15 experiments at between − 10° and − 19° C. they were always active and their oxygen consumption was from 1·6

to 3·4 ml. per g. per hr. In other conditions the temperatures, numbers of trials and oxygen consumption in ml. per g. per hr. were : — 9° to 0° C., active, 26 trials, 1·4 to 2·8 ml. ; quiet, 13 trials, 1·0 to 1·4 ml. ; + 1° to + 20° C., active, 16 trials, 1·3 to 2·0 ml. ; quiet, 37 trials, 0·6 to 1·4 ml. ; + 21° to + 40° C., active, 2 trials, 1·2 and 1·3 ml. ; quiet, 43 trials, 0·6 to 1·1 ml. At 50° C. they could survive for only 1 hr.

After fasting for 24 hr. the squirrels were restless and their oxygen consumption was high. In 2 squirrels studied during sleep, at night, at 30° C., the oxygen consumption was 0·3 to 0·6 ml. per g. per hr., lower than would be expected from the curve of Brody (Abst. 3813, Vol. 15).

The R.Q. was from 0·7 to 0·9 at — 20° to 0° C., 0·8 to 1·2 at + 1° to + 20°, and 1·0 to 1·4 at temperatures above 20° C. High R.Q.s were commonly found only at above 0° C. within 4 or 5 hr. after a meal in autumn, when the squirrels were laying down fat, but in the spring there was no relation between environmental temperature and R.Q.

(b) In unrestrained squirrels free in the cage the body temperature was constant at from 36·5° to 39° C. at environmental temperatures between — 30° and + 30° C. It rose slightly at an environmental temperature of 35° C. and more at 38° C. Restrained animals fastened to a board were unable to withstand an environmental temperature of — 20° C. and were also slightly less able to withstand heat.

(c) Hibernating ground squirrels kept at between 0° and — 8° C. had a rectal temperature of about + 2° C. when undisturbed for several days, but when they were disturbed the temperature rose even if the animal did not wake.—D. Duncan.

HART, J. S. and HEROUX, O. **Utilization of body reserves during exposure of mice to low temperatures.** *Canad. J. Biochem. Physiol.*, 1956, **34,** 414–421. [Div. Appl. Biol., Nat. Res. Labs., Ottawa.]

Two groups, each of 20 adult white mice, were acclimatised for 4 weeks at 22° to 24° C. and 6° to 8° C., respectively ; a high-carbohydrate diet, Master Fox Chow, consisting of protein 15, fat 3 and carbohydrate 82 per cent., was given to appetite. Half the mice, selected at random in each group, were then analysed ; the remainder were exposed to freezing temperatures, the 23° C. mice at — 7° C. and the 6° C. mice at — 13° C. for 4 days with Fox Chow given to appetite and water twice daily. Mice which survived were killed ; all mice were used in subsequent analyses, which included measurements of wet weight, dry weight, ether extract, fat-free dry weight, N in fat-free residue, and heats of combustion of ether extract and fat-free residue.

The mice acclimatised to 6° C. had a body water content greater on an absolute and on a fat-free basis than that of the mice acclimatised to 23° C. When exposed to freezing temperatures the weight loss and loss of water were greater in the group acclimatised to cold. Fat was the major energy reserve used under these conditions ; in both acclimatisation groups it accounted for 85 to 89 per cent. of the total energy, the remainder being supplied mostly by protein. The heat of combustion of the fat of the mice fell during exposure to freezing temperatures, indicating an alteration in chemical composition.—G. F. Garton.

4639

ANDIK, I., NAGY, L. and TÓTH, I. Über die Wirkung der Umgebungstemperatur auf den Stoffwechsel normaler und mit Thyroxin behandelter Ratten. [**Effect of environmental temperature on the metabolism of normal rats and rats treated with thyroxine.**] *Acta physiol. hung.*, 1955, **8,** 399–404. [Pathophysiol. Inst., Med. Univ., Pécs.] Russian summary.

The oxygen consumption over periods of 15 to 20 min. of 8 rats, of bodyweight 180 to 240 g., which had had from 150 to 200 μg. thyroxine daily for from 2 to 6 weeks, and of 8 untreated rats, was measured by Balogh's apparatus (Abst. 124, Vol. 21) at environmental temperatures ranging from 29° to 7° C. and back again to 29° C.

The oxygen consumption of untreated rats showed the expected rise as environmental temperature fell, but that of treated rats fell and was least at 25° C. or even, in some, at 10° or 7° C. In some, oxygen consumption behaved normally about a week after treatment with thyroxine ceased, but in others the effect persisted longer.

Since hyperthermia occurs at 29° C. in rats treated with large doses of thyroxine, it is suggested that the higher oxygen consumption at 29° than at lower environmental temperatures depends on

the same mechanism as the increased rate of energy exchange of normal rats at higher environmental temperatures. Further experiments with urethane and with aminothiazole indicated also that even the minimum oxygen consumption of rats treated with thyroxine depends on regulation through the central nervous system and is not the absolute minimum required for tissue respiration.

VECCHIOTTI, G. Glicemia e alimentazione artificiale del vitello. [**Blood sugar and artificial feeding of the calf.**] *Riv. Zootec.*, 1956, **29,** 75–78. [Ist. Zootec., Fac. Agrar., Piacenza.]

Seven calves were reared on whole milk, which was reduced in amount at 60 days of age and withdrawn at 105 days, and good hay was always available. Blood was withdrawn from the jugular vein every fifth day from 10 to 120 days, 7 hr. after the first feed, and blood sugar was estimated by the Hagedorn Jensen method. Blood from the cows which provided the milk was analysed also, and the average value found was 62 mg. glucose per 100 ml.

Blood sugar values in the calves ranged from 119 to 133, mean 127 mg. per 100 ml. on the 10th day. The values then fell regularly, reaching normal values for adults between 110 and 120 days; at 120 days they were from 60 to 66 mg. per 100 ml.

BLOOM, R. A. and FENTON, P. F. **Glucose tolerance in relation to obesity and food intake.** *Amer. J. Physiol.*, 1956, **184,** 438–440. [Dept. Biol., Brown Univ., Providence, R.I.]

Mice of 2 strains, one the C57BL/Fn and moderately susceptible to nutritional obesity, the other the C_3H/Fn and highly susceptible, were starved for 18 hr. and then given 10 per cent. glucose solution by intraperitoneal injection in amounts providing 1 mg. glucose per g. total or fat-free bodyweight. Sugar was estimated in blood before and ½, 1, 2 and 5 hr. after injections. Of each strain some were fed on a stock ration, others on a diet with 50 per cent. fat. Blood sugar curves showed that with either rate of administration the highly susceptible strain disposed of glucose more rapidly than did the moderately susceptible. Curves for the high-fat group were throughout at a higher level than those for mice on the stock diet. In both strains fasting blood sugar increased with bodyweight and was generally higher for the mice on the high intake of fat.

The findings are not readily explained by the glucostatic theory of the control of food intake (Mayer, Title 2438, Vol. 24 and Review Article, Vol. 25, p. 605).—D. Harvey.

ARENDT, E. C. and PATTEE, C. J. **Studies on obesity. 1. The insulin-glucose tolerance curve. 2. Blood pyruvate and lactate curves in obese and normal subjects after ingestion of glucose.** *J. Clin. Endocrinol.*, 1956, **16,** 367–374; 375–379. [Clin. Invest. Unit, Queen Mary Veterans Hosp., Montreal.]

1. In 32 obese patients, 30 to 130 per cent. overweight, given insulin by vein and 30 min. later glucose by mouth, the initial mean fall in blood sugar was less, and the subsequent mean rise was greater, than in 20 normal subjects. In all of the normal subjects but in only half of the obese subjects blood sugar had returned to fasting levels after 180 min.

2. In 21 obese subjects, 25 to 130 per cent. overweight, the peak of the mean glucose tolerance curve was significantly higher than in a group of 10 normal subjects. There was no significant difference in the pyruvate curves. In the obese subjects, unlike the controls, lactate levels did not fall during the third hour of the study.

SÁNCHEZ AGESTA, A. and NÚÑEZ CARRIL, J. El examen de la regulación glucémica en algunos estados endocrinos. [**Blood sugar regulation in some endocrine disorders.**] *Rev. clín. española*, 1956, **61,** 11–23. [Clín. Méd., Univ. Granada.] English, German and French summaries.

The subjects received after an overnight fast an injection of 0·1 unit of insulin per kg. bodyweight and 30 min. later 0·8 g. glucose per kg. bodyweight by mouth. Blood sugar was studied before and for 180 min. after the injection of insulin. The blood sugar values were expressed as percentages of the initial value.

In 5 normal subjects the curves were all well within the limits of those obtained by Engel and Scott (*J. Clin. Invest.*, 1950, **29,** 151), falling 30 min. after the injection of insulin to between 46 and 66 per cent., reaching a peak of from 121 to 154 per cent. 60 to 90 min. later and reaching 100 ± 20 per cent. after 180 min. from the start.

In 17 patients mostly with endocrine disorders the results varied from the normal. Three subjects with gonadal hypofunction had normal curves, but 2 showed double peaks after the glucose was given and a return to fasting value between. Four hypothyroid patients had low peaks and all had low values 150 and 180 min. after the start of the experiment. In one of them the value fell after insulin to 33 per cent. of normal and even after glucose did not rise during the experiment above 66 per cent. of the fasting value. Similar low values were found in 2 subjects with adrenal insufficiency, one with pituitary insufficiency, and 3 with suspected pituitary insufficiency. Successful treatment in some patients restored the form of the curve to normal.—D. Duncan.

FELTS, J. M., DOELL, R. G. and CHAIKOFF, I. L. **The effects of insulin on the pathways of conversion of glucose to fatty acids in the liver.** *J. Biol. Chem.*, 1956, **219,** 473–478. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

Rats rendered diabetic by injection of alloxan were fed on a high-carbohydrate diet, consisting of glucose 60, casein 22, cellu flour 12 and salt mixture 6 per cent., for several days and then killed. Liver slices were incubated in Krebs Henseleit bicarbonate buffer containing labelled glucose, and production of $^{14}CO_2$ and fatty acid ^{14}C was estimated.

When diabetic rats were treated with insulin there was more increase in recovery of $^{14}CO_2$ from glucose-1-^{14}C than from glucose-6-^{14}C. Insulin also increased the uptake of ^{14}C into fatty acids from glucose-6-^{14}C more than from glucose-1-^{14}C.

It was calculated that insulin increased by about 70 times the amount of glucose-6-^{14}C converted to fatty acids by the Embden Meyerhof pathway, and by 375 times the amount metabolised in the phosphogluconate pathway.—A. K. Lough.

SNEDECOR, J. G., MATHEWS, H. and MACGRATH, W. B. (Jr.) **The blood sugar response of turkey poults to insulin.** *Poultry Sci.*, 1956, **35,** 355–360. [Dept. Zool., Univ. Massachusetts, Amherst.]

Doses of 500 units or less of insulin per kg. liveweight given subcutaneously to day-old turkey poults lowered blood sugar for 5 hr. Higher doses raised the blood sugar. When the insulin was free of glucagon the hyperglycaemic response was not obtained, but the glucagon extracted caused a prolonged rise of blood sugar similar to that produced by the unextracted insulin. It was thought that glucagon was the cause of hyperglycaemia in poults injected with a normal insulin preparation. The difference in response of turkeys and mammals is discussed.—T. D. Bell.

BONDY, P. K. and CARDILLO, L. R. **The effect of glucagon on carbohydrate metabolism in normal human beings.** *J. Clin. Invest.*, 1956, **35,** 494–501. [Dept. Int. Med., Sch. Med., Yale Univ., New Haven, Conn.]

Blood samples were obtained almost simultaneously from antecubital vein and brachial artery. The subjects were adult men without history of disturbed carbohydrate metabolism. Their diet contained at least 250 g. carbohydrate daily, and experiments were made after an overnight fast.

After 2 preliminary blood samples, 6 subjects received 1·0 ml. (0·95 mg.) glucagon intravenously. In 1 subject there was no effect, but in the others the arterial glucose concentration began to rise within 1 to 4 min. and the venous concentration rose somewhat less steeply, so that in 10 min. there was a pronounced arterio-venous difference. In 2 of the same subjects given glucose intravenously the effects were similar to those of

glucagon. In 5 subjects glucagon was given by slow intravenous infusion for 2 hr. The rapid rise in blood sugar and the increase in arteriovenous difference appeared initially, but after about 1 hr. the arterial glucose began to fall, and in 4 of the 5 subjects clinical signs of hypoglycaemia occurred 110 to 120 min. after the infusion began. The venous glucose continued to fall after the end of the infusion.

Serum phosphate declined during infusion of glucagon or of glucose, more with the former. Blood and plasma α-amino N also declined progressively. Ketones were not changed, nor was haematocrit.

The results do not support the suggestion that glucagon can produce diabetes.—D. Duncan.

4652

ELRICK, H. **Glucagon and the regulation of carbohydrate metabolism.** *Nature*, 1956, **177**, 892–893. [Med. Res. Lab., Veterans Admin. Hosp., Denver, Colo.]

Fifty-six normal men were given a diet rich in carbohydrate. When they had fasted for 14 hr. and rested for from 30 to 60 min. glucose was infused for from 30 to 60 min., after which glucagon and insulin were injected separately or in combination. Glucose was estimated in samples of arterial and venous blood taken at short intervals. Glucagon, like insulin, caused an increase in the difference between these and, statistically, the difference was more highly significant. When both were given the difference as significantly greater than when either was given alone. Details are being reported elsewhere (Elrick *et al.*, *J. Clin. Invest.*, 1955, **34**, 1830; 1956, **35**, 757).

PORTMAN, O. W., LAWRY, E. Y. and BRUNO, D. **Effect of dietary carbohydrate on experimentally induced hypercholesteremia and hyperbetalipoproteinemia in rats.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91**, 321–323. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Groups of rats caged individually were fed to appetite for 28 days on a diet consisting of casein 20, maize oil 8, carbohydrate 56, cholesterol 5, celluflour 5 and salts 4 per cent., with vitamins and trace elements. The carbohydrate was maize starch, sucrose, glucose or fructose; to some of the rations was added 1·5 per cent. cholic acid, alone or with 0·2 per cent. Sulfasuxidine (succinylsulphathiazole). Serum cholesterol was estimated in all groups at the end of the experiment; liver cholesterol and serum β-lipoproteins were estimated in animals of some groups.

Rats fed on the diets containing sucrose, glucose or fructose with cholesterol and cholic acid had higher serum cholesterol and serum β-lipoproteins than control animals given maize starch; no difference in liver cholesterol was found.

When the diets contained no cholic acid the rats given maize starch had lower serum cholesterol than those given sucrose. The addition of Sulfasuxidine to sucrose diets did not change serum cholesterol values, though the addition of Sulfasuxidine to starch rations was accompanied by higher serum cholesterol, comparable to values in animals given sucrose.—G. A. Garton.

GOETSCH, D. D., UNDERBJERG, G. K. L. and SWENSON, M. J. **The utilization of intravenously administered glucose, invert sugar, and fructose in cattle.** *Amer. J. Vet. Res.*, 1956, **17**, 213–216. [Dept. Vet. Med., Kansas Agric. Exp. Stat., Manhattan.]

The sugar tolerance curve in cattle was followed after the injection of glucose, fructose and a solution containing equal quantities of each at the rate of 0·5 g. per kg. bodyweight.

Fructose disappeared from the blood more rapidly than glucose or the mixed sugars and less total sugar was excreted in the urine. On account of its apparently greater speed of metabolism it is suggested that fructose might prove useful in the treatment of ketosis in cattle.—A. T. Phillipson.

HILL, R. and CHAIKOFF, I. L. **Loss and repair of a glucose-disposal mechanism in dog fed fructose as sole dietary carbohydrate.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91**, 265–267. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

Three dogs were fed in 7-day periods on diets containing no carbohydrate, then successively received 18 g. glucose, fructose and galactose per kg. bodyweight. At the end of each period the dogs received a test meal containing 4 g. glucose

per kg. bodyweight and blood sugar was studied for the next 4 hr.

The carbohydrate-free diet produced the lowest ability to dispose of glucose. The fructose diet had a similar effect and the blood sugar peak was 190 mg. per cent. after 2 hr. The peaks after the glucose and galactose diets were 120 and 140 mg. per cent. after 1 hr. Three meals containing glucose given after the 7 days on a fructose diet restored the normal ability to dispose of glucose. Similar results were obtained with rats (see Abst. 741, Vol. 25).—A. Hepburn.

4658

SCHEUNERT, A. and SOMMER, H. Der Ernährungseffekt von Kohlenhydraten mit besonderer Berücksichtigung von Milchzucker und Galaktose. [**Nutritive value of carbohydrates with special reference to lactose and galactose.**] *Biochem. Ztschr.*, 1956, **327,** 461–472. [Inst. Ernährungsforsch., Potsdam-Rehbrücke.]

Earlier findings in respect of tolerance for lactose and galactose in diet, the effect of fat and protein on tolerance, the effect of lactose on composition of the body and the possible chemical intermediates in the conversion of galactose to glucose are briefly summarised. Apart from the admitted effects on absorption of Ca, intestinal flora, and synthesis of vitamins, the metabolism of galactose is ill understood.

Eight experiments with rats, with either semi-synthetic diet or modified cow's milk, are described. The semi-synthetic diet was of casein yeast, hydrogenated rapeseed oil, salt mixture and cod liver oil with, as carbohydrate to make up 65 per cent. of the diet, a proprietary dextri-maltose preparation, dextrinised starch, sucrose, lactose, galactose, glucose or a malt extract which were compared over the series of experiments.

Rats did not thrive with lactose or galactose. Water content of the bodies was not changed, but fat was low and ash in fat-free dry matter (DM) was high. Malt extract produced fat amounting to obesity. When the carbohydrates were given with cow's milk at the rate of 6 or 12 g. per 100 ml. galactose was excreted in urine by all groups tested, namely, proprietary preparation, glucose and lactose, 3 times as much with lactose as with the other sugars.

Since sucking rats do not normally excrete galactose in urine, special experiments were planned to study this result and they showed that, at a lactose concentration not exceeding that in rat's milk, 9·1 per cent. in DM, no galactose is excreted so long as the rat does not eat. The limit of tolerance appears to be about the concentration in rat's milk. In cow's milk there is 37·7 per cent lactose in DM, in human milk 56·9 per cent.

With a constant concentration of 5 per cent. sugar in a synthetic diet, glucose gave slightly better weight increase than galactose; at 12 per cent. also, weight increase was greater with glucose and the difference in DM was chiefly in fat. There was little difference in liver fat.—I. Leitch.

4659

PERRY, J. W., MOORE, A. E., THOMAS, D. A. and HIRD, F. J. R. **Galactose intolerance: observations on an experimental animal.** *Acta paediat.*, 1956, **45,** 228–240. [Royal Child. Hosp., Melbourne, N.3.] French, German and Spanish summaries.

Fifty chickens were fed to appetite on standard pellets and were given 10 per cent. galactose in the drinking water. The mean survival time was 4 days, and that of 17 chicks given 5 per cent. galactose was 12 days. Of 9 chicks given 2½ per cent. galactose some survived for 35 days, but the mean time was 21 days. The chicks given 10 per cent. galactose lost weight and had epileptiform fits. In 29 of these chicks blood glucose varied from 110 to 976 mg. per 100 ml. and blood galactose from 16 to 1735 mg. per 100 ml.; in chicks not given galactose, blood glucose was 190 ± 21 mg. per 100 ml. There was no correlation between blood glucose or galactose and the occurrence of fits.

Plasma α-amino N ranged from 5·7 to 10·1, mean 7·6 ± 1·2 mg. per 100 ml. in chickens given galactose, from 6·3 to 15·0, mean 10·5 ± 2·4 mg. per 100 ml., in controls. The levels were restored to normal 6 days after galactose was withdrawn.

Normal chickens 2 to 4 weeks old were starved for 24 hr. before the small intestine was removed. Segments of intestine were incubated in Krebs bicarbonate buffer with L-histidine and 0·5 per cent. glucose or galactose, and dinitrophenol was added at $10^{-3}M$. Uptake of L-histidine from the medium with glucose was greatly reduced by dinitrophenol. Galactose could not supply the energy necessary for absorption of histidine. The integrity of the mucosa was affected in the presence of galactose.

It is suggested that the chicken will be a useful animal for investigation of galactose intolerance such as occurs in children.—D. Duncan.

4660

HANSEN, R. G., FREEDLAND, R. A. and SCOTT, H. M. (with HAGEMAN, E. and KILBOY, C.). **Lactose metabolism. 5. The uridine nucleotides in galactose toxicity.** *J. Biol. Chem.*, 1956, **219,** 391–397. [Lab. Biochem., Dept. Dairy Sci., Univ. Illinois, Urbana.]

Parts 3 and 4 not traced, 1 and 2 Title 4859, Vol. 23.

5. Chickens were fed from hatching on the purified idet of Rutter *et al.* (Abst. 700, Vol. 24), either with glucose as sole source of carbohydrate or

with 15 per cent. galactose replacing part of the glucose. When the group given galactose developed signs of poisoning, after from 6 to 10 days, all the chickens were killed and nucleotide extracts were made from the livers.

Livers from chickens given galactose contained twice as much uridine diphosphate hexose and 1½ times as much uridine diphosphate as those from chickens given only glucose. The uridine diphosphate hexose from both groups contained some galactose, but there was a much larger proportion in the group given galactose.

The possible significance of uridine derivatives in glucose metabolism is discussed.—D. Duncan.

4661

ALTSCHULE, M. D., PERRIN, G. M. and HOLLIDAY, P. D. **Effect of intravenous administration of lactate on blood pyruvate level in man.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 446–448. [Lab. Clin. Physiol., McLean Hosp., Waverley, Mass.]

Lactate infused into 8 normal adults after fasting produced a great increase in the pyruvate concentration in blood. There was no correlation between the rise in lactic acid and that in pyruvic acid. α-Ketoglutaric acid rose in 6 subjects, fell in one and was unchanged in the other. The rise in blood pyruvate after infusion of glucose was not nearly as high as that after infusion of lactate, and this suggests that lactate enters the metabolic pool more rapidly than glucose.—A. Hepburn.

4662

DRURY, D. R. and WICK, A. N. **Metabolism of lactic acid in the intact rabbit.** *Amer. J. Physiol.*, 1956, **184,** 304–308. [Dept. Physiol., Sch. Med., Univ. S. California, Los Angeles.]

Rabbits had a tracheal cannula inserted and a plastic tube in the jugular vein and were then allowed 3 hr. or more to recover from the anaesthetic. Uniformly labelled L(+)-lactate-^{14}C was then given through the jugular tube and respired CO_2 was collected. Blood samples were taken at intervals for estimation of lactate and glucose.

An initial experiment with 2 rabbits showed that rate of removal of lactate from the plasma was about 63 per cent. in 30 min., indicating one turnover of body lactate in that time. In 3 later experiments labelled lactate was injected at a constant rate equal to the initial dose every 30 min. Under these conditions a plateau was maintained in specific activity of respired CO_2 after about the first 30 min. This indicated very rapid combustion of lactic acid, much quicker than that of labelled glucose. Obviously lactate was not converted to glucose before combustion. Only a small proportion of the ^{14}C activity was found in blood glucose and a minute fraction in muscle and liver glycogen.

It is concluded that lactate produced in emergency under the influence of adrenaline can serve as a quick fuel.—D. Duncan.

4663

MCARDLE, B. **Disturbances of carbohydrate intermediaries in nervous disorders.** *Guy's Hosp. Rep.*, 1956, **105,** 129–141. [Med. Res. Counc., Clin. Res. Unit.]

α-Keto and citric acids were estimated in the urine of normal subjects and patients with nervous disorders, and in the cerebrospinal fluid of such patients, as a contribution to the study of the part played by the Krebs cycle in nervous disease. Relevant literature is reviewed.—F. C. Aitken.

4664

RAKER, C. W. and ROGERS, J. A. **Reports of liver glycogen determinations by biopsies on dairy cows.** *Amer. J. Vet. Res.*, 1956, **17,** 205–206. [New Bolton Centre, Univ. Pennsylvania, Kennett Square.]

A technique for obtaining biopsy samples of liver from dairy cattle for estimation of glycogen is described. Blood sugar of 6 cows was estimated before the liver biopsies were made. The values ranged from 37 to 43 mg. per 100 ml. Liver glycogen values on 3 days, separated by intervals of 7 and 5 days, were from 1·95 to 4·70 mg. per g. liver. Lower values were obtained on the last day. When the animals were slaughtered some scars were found in the livers, but the operation did not cause much haemorrhage, shock or decline in milk yield.—T. D. Bell.

4665

LACHAZE, A. and LEVY, M. Étude de la glycogénolyse au cours de la stéatose produite par des régimes hypoprotéiques hyperlipidiques. Action de la choline. [**Glycogenolysis in fatty liver disorders produced by low-protein high-fat diets. Effect of choline.**] *C.R. Soc. Biol.*, 1955, **149,** 1889–1890. [Lab. Physiol. Gén., Sorbonne.]

Rats weighing about 180 g. received for 3 weeks a normal diet or one high in fat and low in protein and were then fasted for 3 days. Blood sugar was studied after an intramuscular injection of 0·2 mg. adrenaline.

The blood sugar peak after adrenaline was small in rats on the high-fat, low-protein diet, but if such rats received 3 mg. choline intraperitoneally for 4 consecutive days the response to adrenaline became normal. It is concluded that mobilisation of liver glycogen in response to adrenaline is reduced in the fatty liver.—D. Duncan.

ALBANESE, A. A., HIGGONS, R. A., HYDE, G. M. and ORTO, L. **Lysine and tryptophan content of proteins and their utilization for human growth.** *Amer. J. Clin. Nutrition*, 1956, **4,** 161–168. [Nutrit. Res. Lab., St. Luke's Hosp., New York.]

The utilisation of dietary proteins by infants, calculated from published data as the product of the change in bodyweight in g. daily and the N retention in mg. per kg. daily divided by 1000, increased as the lysine : tryptophan (L/T) ratio approached that of beef muscle. The average coefficient of utilisation of protein, the utilisation of the test protein divided by that of evaporated milk, was for bovine plasma digest (Travamin) 1·82, beef muscle digest 1·43, evaporated milk 1·0, casein digest (Amigen) 0·95, lactalbumin digest (Edamin) 0·89 and wheat gluten 0·52, with corresponding values of 6·9, 5·9, 4·3, 3·9, 3·5 and 2·1 for the L/T ratios. The coefficient of utilisation of protein was a linear function of the L/T ratio. The growth of 13 infants aged from 1 week to 14 months receiving milk proteins was increased by 250 mg. lysine daily at below, or 500 mg. above 4 kg. bodyweight, so that the L/T ratio was maintained at 6·0 to 7·0 (see previous work, Abst. 5241, Vol. 25).—A. Hepburn.

4669

SHARP, G. S., LASSEN, S., SHANKMAN, S., GEBHART, A. F. (Jr.) and HAZLET, J. W. **Studies of protein absorption using nitrogen^{15} as a tag.** *J. Nutrition*, 1956, **58,** 443–457. [Pasadena Found. Med. Res., Calif.]

Methods for the study of protein absorption in man are reviewed and discussed. A yeast in which the protein was labelled with ^{15}N was prepared ; evidence for the general distribution of the isotope throughout the protein fraction of the yeast is reviewed. Absorption was studied on 6 subjects ; a woman and a man, each aged 24, were controls and had apparently normal gastric function, 2 women aged 57 and 66 had long-standing achlorhydria and 2 women, each aged 70, had well established hypochlorhydria. All received an 1800 Cal. diet which provided much animal protein, on the average 85 g. out of a daily total of 110 g. For 5 days before the labelled yeast was given the patients received 1·83 g. unlabelled yeast with the noon meal, daily ; on the experimental day 2 g. of ^{15}N-labelled yeast was substituted. From 3 days before the administration of ^{15}N all urine and faeces were collected from all patients for analysis.

A mean absorption of 90·3 per cent. of the yeast protein was obtained for the 6 subjects. Achlorhydria, hypochlorhydria and age did not appear to depress the capacity to absorb a protein tracer during high protein intake. The need for direct evaluation of endogenous N was avoided through the use of a single dose of labelled protein.

G. F. Garton.

COHN, T. D., LANE, M., ZUCKERMAN, S., MESSINGER, N. and GRIFFITH, A. (with ELKAN, B.) **Induced azotemia in humans following massive protein and blood ingestion and the mechanism of azotemia in gastrointestinal hemorrhage.** *Amer. J. Med. Sci.*, 1956, **231,** 394–401. [Jewish Hosp., Brooklyn, N.Y.] Interlingua summary.

Five healthy men were the subjects in 10 trials. In 2 sets of 3 trials 180 g. protein were given as diluted citrated human blood or as a protein concentrate, Protinal ; in 2 sets of 2 trials 100 and 140 g. were given as beefsteak and 230 and 262 g. as a mixture of beefsteak and concentrate. The blood was taken by stomach tube without ill effect. Urea in blood and N in urine were measured at intervals up to 24 hr. after the protein had been given.

In blood urea the changes were : with blood, increases in 5 hr. of 4, 5 and 7 mg. per 100 ml., equivalent to from 25 to 35 per cent. of fasting value, and return to that value within 24 hr. ; with protein concentrates corresponding results were in from 7 to 9 hr., 19, 20 and 21 mg., 100 to 119 per cent., but after 24 hr. fasting value had not been attained ; with beefsteak alone or with concentrate, results were in from 6½ to 10 hr. between 14 and 45 mg., 67 and 237 per cent., and again fasting value was not reached in 24 hr. Total N in urine in 24 hr. was, for protein concentrate,

about twice that for the equivalent amount of blood ; with the different amounts of beefsteak and concentrate it was directly proportional to the intake of N.

The finding that the protein of whole blood is absorbed less readily than that from the other sources is discussed in relation to the results of other workers on severe gastrointestinal haemorrhage and impairment of kidney function.

PEARSON, E., SOROFF, H. S. and REISS, E. **Metabolic derangements in burns.** *J. Amer. Dietetic Assoc.*, 1956, **32,** 223–228. [Surg. Res. Unit, Brooke Army Med. Centre, Fort Sam Houston, Tex.]

Balances of N, K, P, Mg, Na and Cl were studied in 7 burned patients. During the period of negative N balance which followed injury there were large losses of all the elements studied. Comparisons of the balances of N, P and K indicated that losses of protoplasm did not completely explain the changes, nor did the subsequent gains of N correspond with the theoretical gains calculated from K and P balance data.—F. C. Aitken.

4672

LEGUN, A. F. Vliyanie dlitel'nogo medikamentoznogo sna na azotistyi obmen i obmen kaliya i kal'tziya u bol'nykh yazvennoi boleznyu. [**Influence of prolonged induced sleep on nitrogen, potassium and calcium balances in ulcer patients.**] *Vop. Pitan.*, 1956, **15,** No. 3, 16–22. [Lab. Obmen. Veshchestv, Inst. Pitan., Akad. Med. Nauk SSSR, Moscow.]

There were 2 groups of 5 men between 27 and 45 years old. Mineral and N balance was studied before, during and after treatment. For the 8 days of treatment sleep was prolonged with sedatives to about 20 hr. daily in the first and up to 14 hr. in the second group. The third period began on the twelfth day after the end of treatment. The diet was constant. The results for the first group only are given.

The N balance was studied before treatment in 4 subjects ; it was negative in 3 and 1 was in equilibrium. During treatment all 5 gained weight and were in strongly positive N balance, retaining from 4 to more than 8 g. daily. Appetite was improved considerably in only 1 patient. In the third period weight was maintained and N balance remained positive but retention was smaller, mean 1·6 g. daily, in 4 subjects. The increase in weight during treatment, which varied from 1·3 to 5·3 kg., was not due to retention of water, because an increased intake of water was followed by increased output in the urine.

Mean daily retention of K in the 3 successive periods was 0·7, 3·3 and 3·1 g., that of Ca 0·2, 0·8 and 0·6 g.—D. Duncan.

4673

MCNAIR, R. D., QUIGLEY, W. and O'DONNELL, D. **Protein nutrition in surgical patients. 2. A comparison of the nitrogen-sparing action of glucose, invert sugar and fructose.** *Ann. Surg.*, 1956, **143,** 448–451. [Dept. Pathol., 2. Providence Hosp., Detroit, Mich.]

It has been observed that infused amino acids leave the circulation much sooner than infused glucose and at about the same rate as infused fructose. This suggested that fructose infused with amino acids might have a greater N-sparing effect than infused glucose. This was not borne out by the results of intravenous feeding of 28 subjects with protein hydrolysate and glucose, invert sugar or fructose, for 1 to 3 days. Nitrogen balances were not significantly different in the 3 groups.—F. C. Aitken.

DE VEGA RUIZ, T. Estudio del catabolismo proteico en los periodos pre y postoperatorios. Influencia de la hormona del crecimiento y de los frenadores del sistema hipofisis suprarenal. [**Protein breakdown before and after operations. Influence of growth hormone and of inhibitors of the pituitary adrenal system.**] *Cirug., Ginecol. Urol.*, 1955, **9,** 289–326. [Univ. Seville.]

Excretion of N in the urine was studied in patients after injury or before and after surgical procedures. The first study was on 4 groups of patients ; 26 had abdominal operations causing little trauma, 4 had more severe abdominal operations, 18 had minor and 14 major operations involving injury to bones. All these subjects, with one exception, showed increased loss of N after operation. In 8 out of 18 subjects in whom this aspect was studied the loss reached its peak on the third post-operative day. In 18 out of 19 subjects the return to normal N excretion was delayed beyond the fourth day. The amount of the increase was less than 50 per cent. of the pre-operative output in 11 subjects, 50 to 100 per cent. in 13 and more than 100 per cent. in 36. The proportion of subjects with an increase of more than 100 per cent. was highest in the groups which had the most severe trauma. The type of anaesthesia, spinal or general, had some effect, and losses of N tended to be large after general anaesthesia with ether and chloroform. [The possibility of correlation between the type of anaesthesia and the degree of surgical trauma is not discussed.] Rise of body temperature was often related to a large loss of N.

The second study was on 30 subjects treated after operation with a pituitary inhibitor, *p*-oxypropiophenone (Frenormón); they received in the first 3 days totals of from 0·8 to 1·6 g. The expected increase in loss of N was prevented in 5 of these patients, 2 after minor and 2 after major abdominal operations and 1 with a fractured forearm. [This study included no patient with major bone damage.] The mean loss of N was considered to be reduced by treatment with *p*-oxypropiophenone.

A further 25 patients were treated after operation with gonadotropic hormone. This prevented increase in loss of N in 8 subjects. The peak of loss was less uniform in this group and its timing ranged in 7 subjects from the first to the fifth day, and the total effect was not to improve loss of N except in those subjects in whom the increase was completely abolished.

Growth hormone, given to 15 patients, prevented increased loss of N in 4, but not in any of the 5 with major bone injury. The mean loss of N was reduced in this group and the phase of loss was shortened.

The results were confirmed in experiments with 21 rabbits subjected to abdominal surgery or bone trauma. Again, the best results were obtained with growth hormone.—D. Duncan.

PLOUGH, I. C., IBER, F. L., SHIPMAN, M. E. and CHALMERS, T. C. **The effects of supplementary calories on nitrogen storage at high intakes of protein in patients with chronic liver disease.** *Amer. J. Clin. Nutrition*, 1956, **4**, 224–230. [Dept. Metabol., Med. Div., Army Med. Serv. Grad. Sch., Walter Reed Army Med. Centre, Washington 12, D.C.]

Three patients with chronic liver disease, after a control period on a diet containing sufficient protein and energy to maintain positive N balance and a reasonably constant bodyweight, were given a supplement of 1000 Cal. in the form of fat, carbohydrate or both. The effects of the supplements on N balance were studied at protein intakes ranging from 1 to 4 g. per kg. bodyweight daily.

The amount of N spared ranged from 1·4 to 6·5 mg. per added Cal. In 2 patients fat and carbohydrate were equally effective, in the third carbohydrate was twice as effective as fat.

BENDER, A. E. **Relation between protein efficiency and net protein utilization.** *Brit. J. Nutrition*, 1956, **10**, 135–143. [Bovril, Ltd., 148 Old St., London, E.C.1.]

The net protein utilisation and the protein efficiency ratio of 32 proteins and 5 amino acid mixtures were estimated with groups of 4 rats given a basal diet of potato starch 10, glucose 15, rice starch 55, margarine fat 15 and salt mixture 5 per cent., with supplements of all the known vitamins; the proteins and amino acids to be tested replaced the rice starch in such quantity that the experimental diet contained 1·4 to 1·6 per cent. N. The duration of each experiment was 7 or 10 days; the rats changed abruptly from stock to experimental diet and were killed at the end of the experimental period; liveweights were used to calculate protein efficiency ratios and dead weights to calculate the moisture content and hence the N content.

The protein efficiency ratios were correlated closely with food intake; the net protein utilisation was independent of food intake. Food intake was correlated with the nutritive value of the protein measured by net protein utilisation or protein efficiency ratio. For net protein utilisation the relation was $y^2 = 67x - 3891$, where y = net protein utilisation and x = food intake in g. per 100 g. bodyweight; for protein efficiency ratio the relation was $y^2 + 20y = 1{\cdot}55x - 135{\cdot}4$. The intake of diets containing amino acids was only half that of diets with protein of similar net protein utilisation, which depressed protein efficiency ratios, so that the relation between protein efficiency ratio and net protein utilisation found with proteins did not hold for the synthetic amino acid mixtures. The protein efficiency ratios were highly correlated with the net protein utilisation values. It was shown that net protein utilisation can be correlated with negative protein efficiency ratios, *i.e.*, loss of weight in g. per g. protein eaten.

CARPENTER, K. J. and ELLINGER, G. M. **Protein quality and "available lysine" in animal products.** *Poultry Sci.*, 1955, **34**, 1451–1452. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Since the ϵ-NH_2 group of lysine was thought to form a nutritionally unavailable complex when intact proteins are damaged during processing, the free NH_2 groups were estimated by reaction with dinitrofluorobenzene and available lysine values were then calculated for 18 products of animal origin. A significant correlation was found between available lysine and the gross protein values obtained by the method of Carpenter *et al.* (Abst. 1281, Vol. 26). The available lysine values were thought to be useful for the prediction of protein quality of animal products of the type investigated when biological tests are not possible.

HEINICKE, H. R., HARPER, A. E. and ELVEHJEM, C. A. **Protein and amino acid requirements of**

the guinea pig. 2. Effect of age, potassium and magnesium and type of protein. *J. Nutrition*, 1956, **58**, 269–280. [Dept. Biochem., Univ. Wisconsin, Madison.]

For part 1 see Abst. 3273, Vol. 26.

2. Four experiments are reported. In the first the synthetic diet, similar to that already described, had 24 per cent. casein ; it was given alone or with 0·5 per cent. L-arginine hydrochloride or 0·3 per cent. DL-methionine or both ; a fifth group had the diet with 35 per cent. casein. Control periods lasted for 5 weeks with these mixtures after which there was added to each 0·1 per cent. DL-tryptophan for 2 weeks, the same amounts of arginine and methionine for 1 week and with tryptophan for 12 days and finally 0·1 per cent. L-arginine hydrochloride for 10 days. In the control period, when additions were to the 24 per cent. casein diet, arginine greatly increased the rate of growth, methionine had little effect and together these amino acids had more effect than arginine alone. Only on the diet with 35 per cent. casein was growth satisfactory.

In the second experiment with the same guinea-pigs, now older, graded amounts of arginine, 0·1, 0·3 or 0·6 per cent., were added to the 24 per cent. casein diet ; growth was best at the intermediate level. When methionine was added in graded amounts with 0·3 per cent. arginine no benefit resulted.

In the third experiment levels of casein and of sucrose or dextrin were as in Abst. 3273, Vol. 26 and the effects were studied of adding extra K or Mg or both or of excluding both. In these last circumstances growth ceased ; it recommenced when one or the other was restored to the diet, but was satisfactory only when both were given.

In the last experiment different proteins were tested, 24 per cent. casein, 18 per cent. casein with 6 or 10 per cent. gelatine, or 24 per cent. soya bean protein. Growth was best with the soya protein ; the inclusion of gelatine improved growth slightly.

The findings are discussed.—D. Harvey.

4679

GESSERT, C. F. and PHILLIPS, P. H. **Protein in the nutrition of the growing dog. Adverse effects of some amino acid supplements in low-protein diets for growing dogs.** *J. Nutrition*, 1956, **58**, 415–421 ; 423–431. [Dept. Biochem., Univ. Wisconsin, Madison.]

(a) Eight pups, one from each of 8 litters, were assigned to each of 5 experimental groups. The diets of the groups contained 10·6, 12·8, 15·0, 17·2 and 19·4 per cent. protein. Each increment of protein over 10·6 per cent. was obtained by replacing sucrose by casein. The dogs were given the experimental diets for 14 weeks or more from the age of 6 or 7 weeks. Average gain in weight in 12 weeks increased with increase in protein content of diet up to 17·2 per cent. Efficiency of utilisation of diet increased rapidly from the 10·6 to the 12·8 per cent. protein level ; thereafter there was little increase in efficiency. One male pup weighed only 2·45 kg. after 16 weeks on the diet of lowest protein content and its female littermate weighed 10·05 kg. after 16 weeks on the diet of highest protein content, but the male achieved a weight of nearly 10 kg. when given the diet with 17·2 per cent. protein for the next 14 weeks.

The estimated amino acid contents of the 5 diets are tabulated and discussed in relation to the requirements of the dog for individual amino acids.

(b) Five groups of littermate pups were given a basal diet containing 10·6 per cent. protein. Average gain in weight in 10 weeks was poorer in an unsupplemented group than in a group which received a supplement of 10 per cent. casein. A group given a supplement of 0·4 per cent. L-lysine did not gain as much as the unsupplemented group and the gains of groups given 0·4 per cent. L-lysine with 0·3 per cent. DL-methionine, with or without 0·13 per cent. L-histidine, were little better than those of the unsupplemented group. In a second similar experiment a supplement of 0·15 per cent. DL-methionine, with or without 0·10 per cent. DL-tryptophan, depressed growth compared with that of an unsupplemented group. Addition of 0·15 per cent. DL-methionine with 0·13 per cent. L-lysine and with or without 0·10 per cent. DL-tryptophan substantially increased weight gain above that of the unsupplemented group.

MEYER, J. H. **Influence of dietary fiber on metabolic and endogenous nitrogen excretion.** *J. Nutrition*, 1956, **58**, 407–413. [Dept Animal Husb., Univ. California, Davis.]

Four groups of 12 weanling rats were given a basal ration of sucrose 86·8, defatted whole egg protein 4, cottonseed oil 5, salts 4, vitamins 0·1 and choline 0·1 per cent. Three of the groups were given 5, 15 and 30 per cent. cellulose at the expense of the basal ration, so that the ratios of sucrose and fat to protein, vitamins and minerals remained constant. After 7 days on the diets, the faeces and urine were collected for 7 days and N was estimated.

There was no effect of fibre intake on excretion of endogenous N in the urine. Each increment of cellulose increased total faecal N excretion ; this relationship was examined and expressed graphically and by the regression equation

$$y = 3{\cdot}1 + 115{\cdot}45\ (1/x),$$

where y is metabolic N in mg. per g. faecal dry matter and x the percentage of indigestible dry matter in the diet.—G. F. Garton.

RUMSFELD, H. W. (Jr.) **Role of dietary protein in normal rat proteinuria.** *Amer. J. Physiol.*, 1956, **184,** 473–478. [Dept. Biochem., Southwestern Med. Sch. Univ. Texas, Dallas.]

Eleven groups of 5 adult rats were given diets containing, respectively, 50 per cent. casein, 18 per cent. casein, 18 per cent. casein plus urea, 50 per cent. egg albumin, 50 per cent. fibrin, 50 per cent. casein and fibrin mixed, 50 per cent. casein and egg albumin mixed, 50 per cent. " synthetic " casein, 12 per cent. casein, 50 per cent. casein (other items different from those in diet 1), and 12 per cent. casein plus 12·5 per cent. urea. Urine was collected for estimation of urea, N.P.N., ammonia and protein N and for electrophoretic analysis ; blood samples were obtained for estimation of urea N.

When the casein intake was increased from 12 or 18 to 50 per cent. the amount of protein in the urine doubled ; the same effect was produced by the other proteins studied. The electrophoretic pattern of the protein in urine was not affected by the nature of the dietary protein. Urea when given by mouth or by injection caused an increase in protein in urine, similar in many respects to that produced by intact protein. Water loading experiments showed a much closer relation between urea and protein excretion than between protein excretion and urine volume.—G. F. Garton.

4682

FRITZ, I. **The effects of the adrenal cortex on the release of N^{15} from tissue proteins of rats previously fed N^{15}-glycine. The preferential catabolism of recently synthesized protein during starvation.** *Endocrinology*, 1956, **58,** 484–492 ; 493–500. [Dept. Dent. Res., Dent. Div., Army Med. Serv. Grad. Sch., Washington, D.C.]

(a) Rats given ^{15}N-glycine and then starved for up to 161 hr. excreted more ^{15}N in the urine when they received cortisone than did normal or adrenalectomised rats. Cortisone prevented the decrease of total protein N in the liver, enhanced the decrease in thymus, but had no effect on the heart, kidney and testis, which lost little protein during starvation. Neither cortisone nor adrenalectomy affected the rate of decrease of ^{15}N in tissue proteins. Cortisone was thought to mobilise the protein from the periphery to the liver faster than the liver could catabolise it.

(b) When normal rats were starved the ^{15}N concentrations of all tissue proteins, except incisor dentine (Fritz and Burnett, *J. Dent. Res.*, 1953, **32,** 647) and hair, failed to increase. The ^{15}N concentrations in the N.P.N. fractions of carcase, heart, diaphragm and biceps were always greater than those of the corresponding tissue proteins and decreased rapidly with time. All fractions obtained by differential centrifuging of liver from starved rats treated with cortisone retained more protein N than corresponding fractions from normal starved rats, but the ^{15}N concentrations of the fractions after 161 hours' fasting were not affected by cortisone. Recently formed protein was thought to be broken down preferentially.

A. Hepburn.

4683

CANNON, P. R., FRAZIER, L. E. and HUGHES, R. H. **The influence of cortisone upon protein metabolism.** *Arch. Pathol.*, 1956, **61,** 271–279. [Dept. Pathol., Univ. Chicago, Ill.]

Eight experiments were made with adult male rats. The method used was mainly one of repletion of animals which had been depleted of protein ; the standard repletion diet was of dextrin 69·5, maize oil 4, cellulose 7·5, K-free salt mixture 5·6, vitamin mixture 1·5, fibrin 15·07 per cent., choline 0·9 ml., water 11 ml., percomorph liver oil 0·45 ml. and KCl 0·1 per cent.

Using " catabolism " in a general sense, namely, in relation to a trend towards a negative N balance and an inhibition of tissue protein synthesis, it was evident from the experiments that cortisone acted as a catabolic agent. Inhibition was not modified by dietary supplements of ascorbic acid or certain of the B group vitamins, including cyanocobalamin. An increase of energy intake during protein repletion favoured weight gain, but carcase analysis indicated that this was due to increased deposition of tissue carbohydrate and fat, not to increased deposition of tissue N. No evidence was obtained that the K ion limited the inhibiting action of cortisone. Although cortisone acted to divert dietary protein from its usual role in the synthesis of depleted tissues, there was no evidence of toxicity such as might have been shown by loss of appetite.—G. F. Garton.

LEVERTON, R. M., JOHNSON, N., ELLISON, J., GESCHWENDER, D. and SCHMIDT, F. **The quantitative amino acid requirements of young women. 4. Phenylalanine, with and without tyrosine.**

LEVERTON, R. M., ELLISON, J., JOHNSON, N., PAZUR, J., SCHMIDT, F. and GESCHWENDER, D. **5. Leucine.** *J. Nutrition*, 1956, **58,** 341–353 ; 355–365. [Nebraska Agric. Exp. Stat., Lincoln.]

For parts 1 and 2 see Abst. 3538, Vol. 26.

4. The method was that described previously (Abst. 3538, Vol. 26). Ten college girls served as subjects. The daily N intake of each subject was 9·5 g. Phenylalanine intake was reduced from 1280 to 320, to 220, to 120 and to 70 mg. daily while tyrosine was kept constant at 900 mg. An intake of 220 mg. phenylalanine was the least amount which maintained all the subjects in N equilibrium, defined as the condition in which N excretion remains within 95 to 105 per cent. of the intake. When the subjects received other proportions of phenylalanine and tyrosine no clear-cut quantitative relation between them was found; a sparing action of tyrosine on phenylalanine requirement was evident.

A group of 8 subjects remained in N equilibrium on a ration which included 220 mg. phenylalanine, 900 mg. tyrosine and the minimum amounts of threonine, valine, tryptophan and leucine previously found in this series of experiments to be required by young women for maintaining N balance. In the presence of 900 mg. tyrosine, 220 mg. phenylalanine is tentatively suggested as the minimum daily requirement of young women.

5. The leucine requirement of 12 young women was studied as above. Leucine intakes of 1860, 710, 620, 480, 370, 270, 170 and 95 mg. daily were used.

The amount of leucine required to maintain N equilibrium ranged from 170 to 710 mg. daily. When 620 mg. leucine was included in a ration with minimum amounts of threonine, valine, tryptophan and phenylalanine given to 8 subjects they all remained in N equilibrium. The minimum daily requirement of L-leucine for young women is tentatively suggested to be 620 mg.—G. F. Garton.

4686

SCHÖNENBERG, H. Papierchromatographische Untersuchungen der Aminosäurenausscheidung im Urin gesunder Menschen. [**Investigation by paper chromatography of the amino acid excretion in the urine of healthy human beings.**] *Klin. Wochenschr.*, 1956, **34,** 442–446. [Kinderklin., Univ. Münster i. W.]

The distribution of amino acids in urine was investigated by a 2-dimensional paper chromatogram with phenol as solvent in the first phase and a mixture of collidine and lutidine in the second phase. Results from 100 patients in an asylum, 100 healthy students, 25 newborn infants and 75 older infants are tabulated. Glycine and serine were present in all the urines examined, and alanine, histidine and glutamic acid in over 90 per cent. of samples from adults, but in fewer from infants. Hydroxyproline was found only in infant urine. The possible use of paper chromatograms of urinary amino acids for diagnosis of metabolic disorders is suggested.—A. M. Copping.

BERGER, H. Die Amino-Stickstoff-Ausscheidung im Harn in Abhängigkeit vom Lebensalter. (Ein Beitrag zur Physiologie der Aminoacidurie.) [**Excretion of amino acids in urine as related to age. Contribution to the physiology of urinary excretion of amino acids.**] *Ann. paediat.*, 1956, **186,** 338–361. [Kinderklin., Kinderspital, Univ. Basle.] English and French summaries.

Previous work (Abst. 3748, Vol. 24) had shown that the amount of amino N excreted in the urine in 24 hr. did not vary much from day to day in any one person, but did vary with age. To study this, α-amino N was estimated in 24-hr. urine, 400 samples from 340 healthy persons of all ages, by a modification of Folin's method, and in some samples total N.P.N. was estimated by the Kjeldahl method. The results are shown mostly in scatter diagrams.

Values for 50 normal newborn infants, mostly fed on mother's milk from the second day, rose fairly regularly from about 2·5 mg. in the first 24 hr. to about 10 mg. on the 7th day. Urine volume rose in much the same way, but they are not thought to be directly connected. Neither was related to bodyweight.

After the neonatal period, excretion of α-amino N rose from 10 mg. at 1 year to a maximum of about 200 mg. at puberty, fell to a plateau at about 130 mg. in the third decade and thereafter declined gradually. In old age there were great fluctuations even in the same person. As a percentage of total N.P.N., α-amino N fell from about 6 in the first week to under 2 at 1 year and remained so for the rest of life, except possibly at puberty and in old age. Relative to bodyweight, α-amino N, at first very low, rose rapidly to 10 mg. per kg. bodyweight and then declined gradually, with a slight rise at puberty and perhaps in old age.

The results are in fairly good agreement with comparable ones in the literature, but the peaks at puberty and in old age do not seem to have been reported before.

Total N.P.N. excreted per kg. bodyweight in 24 hr., apart from the first few months of life and a slight rise at puberty, was found to decline steadily with age, and it is suggested that amino N excretion, which bears a nearly constant ratio to it, runs parallel with the protein turnover. It also accords with textbook values for protein requirement relative to bodyweight, at different ages, except perhaps in old age.

When the absolute amount of amino N excreted was plotted against bodyweight, it was found that the greatest amounts were excreted not by the heaviest people, but by those of medium weight, 30 to 60 kg., and it is conjectured that in the heavy

" well fed " people the smaller excretion of amino N may be the sign of a smaller turnover of protein due to the sparing effect of the reserves of carbohydrate and fat.

The relation between surface area and excretion of amino N seemed to be almost linear ; between urine volume and excretion of amino N there was no consistent trend.—W. M. Deans.

4688

FISHER, I., GUTH, D., HIRSCH, W. and PHARAON, H. Zwei Fälle von Aminosäurendiabetes. [**Two cases of amino acid diabetes.**] *Helv. paediat. Acta*, 1956, **11**, 99–103. [Kinderabt., Hadassah Spital, Tel Aviv.] French, Italian and English summaries.

Two young children had renal glycosuria and cystinuria, respectively, and further investigation showed excessive loss of amino acids in the urine and disturbances of mineral metabolism. Both children were physically and mentally retarded. The rest of the family of one child also excreted excessive amounts of amino acids, and 2 brothers of the other child had cystine crystals in the urine. The condition is considered to be an inborn error of metabolism.—W. M. Deans.

4689

DALGLIESH, C. E. and TABECHIAN, H. **Comparison of the metabolism of uniformly ^{14}C-labelled L-phenylalanine, L-tyrosine and L-tryptophan in the rat.** *Biochem. J.*, 1956, **62**, 625–633. [Postgrad. Med. Sch., Ducane Rd., London, W.12.]

Fasted rats received by stomach tube phenylalanine, tyrosine or tryptophan uniformly labelled with ^{14}C and total radio-activity in respired CO_2, muscle, bone, skin and different organs was estimated. The activity in urine and faeces was small and was neglected.

The rate of production of $^{14}CO_2$ showed that all the amino acids were rapidly degraded to non-aromatic substances of high activity. Tyrosine was degraded about twice as fast as phenylalanine and tryptophan. The activity in the " non-protein aromatic " fraction of muscle, liver and gut, the tissues containing most activity, was low except after short intervals of time, but the activity of the " protein-bound " fraction increased with time. Tryptophan produced much greater activity in the gut than the other amino acids, and the ratio of activity in the gut to that in the blood protein was high. These results suggested that tryptophan remained longest in the gut wall. The degradation of tryptophan to non-nitrogenous substances is considered likely to occur via 3-hydroxyanthranilic acid.—A. Hepburn.

4690

LOFTFIELD, R. B. and HARRIS, A. **Participation of free amino acids in protein synthesis.** *J. Biol. Chem.*, 1956, **219**, 151–159. [Med. Labs., Collis P. Huntington Mem. Hosp. Harvard Univ., Massachusetts Gen. Hosp., Boston.]

L-Valine, L-*iso*leucine and L-leucine, all labelled with ^{14}C, were infused continuously into rats for 3 days. Saccharated iron oxide was injected after the beginning of infusion to stimulate formation of ferritin in the liver. After an interval the ferritin had the same radio-activity in its amino acids as the liver tissue. It was therefore concluded that ferritin was synthesised directly from free amino acids and not from other proteins. Unlabelled leucine infused 24 hr. after a large dose of ^{14}C-leucine produced intracellular leucine with a specific activity higher than the average activity of the total liver protein for at least 1 day. This showed that much of the free amino acids within liver tissue was derived from endogenous protein.—A. Hepburn.

SÓS, J. and KEMÉNY, T. Die characteristischen Symptome des Isoleucin-, Lysin- und Methioninmangels bei Ratten und Hunden. [**The characteristic signs of *iso*leucine, lysine and methionine deficiency in rats and dogs.**] *Virchows Arch.*, 1956, **328**, 421–428. [Pathophysiol. Inst., Med. Univ., Budapest.]

See also Abst. 2012, Vol. 26.

The diets of rats contained 18 per cent. and those of dogs 15 per cent. total protein. For the control diet the protein was casein, for *iso*leucine deficiency blood protein, for lysine deficiency wheat gluten and for methionine deficiency gelatine. The degree of deficiency was 70, 70 and 85 to 90 per cent., respectively. The numbers of rats and dogs given the 4 diets in the above order were 20 and 2, 10 and 2, 20 and 3, 20 and 2. The dogs were all of one litter.

In lysine deficiency the rats failed to grow, and after about 20 weeks began to lose weight quickly and soon died. Deficiency of methionine had a much more acute course ; the rats lost weight from the start and died in about 2 months. The effect of *iso*leucine was intermediate. The rats deprived of lysine became ataxic and adopted a characteristic stance suggestive of damage to the brain.

The relative weights of different organs in the 3 types of deficiency were compared with those in controls. *Iso*leucine deficiency produced damage especially in the kidneys, where both glomeruli and tubules showed degenerative changes. The thyroid showed areas of increased and others of reduced activity. Slight parenchymatous degeneration appeared in liver and lungs.

Lysine deficiency damaged chiefly the liver, which showed advanced perilobular fatty degeneration. Most of the rats had chronic pneumonia. No clear lesion was found in the central nervous system. Methionine deficiency produced fibrocystic damage in the pancreas, then fatty degeneration, necrosis and fibrosis in the liver and emphysema and bronchiectasis in the lungs. Other organs were more or less damaged also.

In all 3 deficiencies the adrenals were 3 times as large as those of controls as a result of cortical hypertrophy.—D. Duncan.

STENRAM, U. **Nucleolar size in the liver of rats fed diets deficient in essential amino acids.** *Acta pathol. microbiol. scand.*, 1956, **38,** 364–374. [Dept. Histol., Univ. Lund, Sweden.]

Thirteen groups of 10 adult male rats after being starved for 5 days were fed for 3 days on diets containing 25 per cent. casein, no casein, histidine and the 8 essential amino acids with glycine to 25 per cent., the third diet with one of the essential amino acids or histidine omitted, or 25 per cent. glycine alone. Food intake was restricted to that of the group eating least. When lysine, *iso*-leucine, methionine, threonine, tryptophan or valine was omitted from the diet, nucleolar size, total nucleolar volume per nucleus and the ratio of total nucleolar volume per nucleus to nuclear volume of rat liver cells was significantly increased as compared with that of the groups given all the amino acids or casein. These results were verified with 43 female rats. The omission of histidine, leucine or phenylalanine had no effect, and when all 3 were omitted from the diet of 20 young male rats there was again no change.—A. Hepburn.

BROWN, R. R. and PRICE, J. M. **Quantitative studies on metabolites of tryptophan in the urine of the dog, cat, rat and man.** *J. Biol. Chem.*, 1956, **219,** 985–997. [Cancer Res. Hosp., Med. Sch., Univ. Wisconsin, Madison.]

Procedures with ion exchange resins are described in detail for estimation in urine of kynurenic and quinaldic acids, 4-quinolone and its *N*-methyl derivative, anthranilic acid and its glucuronide, kynurenine and its acetyl derivative and *o*-aminohippuric acid. These and xanthurenic acid and *N*-methyl-2-pyridone-5-carboxamide were estimated in urine from 4 healthy men, 2 dogs, 2 cats and 5 rats before and after doses of L-tryptophan given, respectively, by mouth, stomach tube, mouth and intraperitoneal injection.

Cats differed from the other species in excreting almost none of these substances; *o*-aminohippuric acid alone appeared in measurable amount and only 0·07 per cent. of a dose of 4·9 m. moles of tryptophan was accounted for. The main metabolites in the other species were kynurenine and kynurenic acid with, in man, the pyridone. Xanthurenic acid appeared to some extent in urine from both man and rat, but was of little importance in that of the dog. 4-Quinolone and its *N*-methyl derivative were not detected in urine from any of the species.

The relation of these findings to the occurrence of cancer of the bladder, frequent in man and rare in cats, is discussed.—D. Harvey.

KOTAKE, Y. (Jr.) and INOUYE, K. **Effect of tryptophan and anthranilic acid upon adrenalectomized rat. 1. The prolongation of life of adrenalectomized rat by the oral application of tryptophan and its metabolite, anthranilic acid.**

KOTAKE, YAHITO, INOUYE, K. and NAKAI, O. **2. Studies on the protein metabolism.** *J. Biochem., Tokyo*, 1955, **42,** 513–518; *Proc. Japan Acad.*, 1955, **31,** 745–749. [Biochem. Dept., Wakayama Med. Coll.]

1. Groups of from 3 to 7 rats, weighing from 140 to 290 g., fed on a semi-synthetic diet survived for from 4 to 10 days after removal of the adrenals, but 100 mg. tryptophan given by mouth at intervals afterwards prolonged survival to from 20 to 43 days, and a daily dose of 2·5 mg. anthranilic acid prolonged it to from 20 to 27 days. When 1 mg. nicotinic acid or 1 mg. vitamin C or 20 mg. L-methionine was given daily there was no influence on survival.

When 2·5 mg. anthranilic acid or 15 mg. tryptophan was given daily the liver glycogen of adrenalectomised rats remained almost normal, otherwise it fell considerably within 3 days.

2. In an experiment like the last, anthranilic acid or tryptophan maintained the creatinine content of the urine at almost the normal; in untreated rats it fell rapidly. Anthranilic acid prevented the fall in urea content of the urine and the increase in N.P.N. content of the blood which occur after adrenalectomy in untreated rats.

Histological examination of the livers of adrenalectomised rats, given and not given anthranilic acid, showed changes in the appearance of ribonucleic acid as stained with thionin, suggesting that after adrenalectomy the liver undergoes some

biochemical change adversely affecting protein metabolism, which can be prevented with anthranilic acid.—M. H. Pierce.

WRETLIND, A. **The utilization of D-valine for growth of rats.** *Acta physiol. scand.*, 1956, **36,** 119–136. [Dept. Pharmacol., Karolinska Inst., Stockholm.]

A diet containing 2 per cent. D-valine and the essential amino acids in the racemic form did not support growth in normal rats or rats depleted of protein. The diet of White *et al.* (Abst. 3214, Vol. 23) containing all the L-amino acids except valine (methionine, threonine, alanine and serine were racemic) produced growth when D-valine was added. Systematic study showed that the conversion of D-valine into the L-form was inhibited by D-leucine.—A. Hepburn.

PORTMAN, O. W. and MANN, G. V. **Further studies of the metabolism of taurine-S^{35} by the rat.** *J. Biol. Chem.*, 1956, **220,** 105–112. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

For previous work see Abst. 5250, Vol. 25.

Rats were given intraperitoneally taurine labelled with taurine-^{35}S and its fate was studied. In 16 adult rats the proportion of the dose which was recovered in urine in 24 hr. after the injection rose from a mean of 29·1 per cent. to 69·0 per cent. as the dose increased from 4·8 to 60·0 mg. taurine per kg. bodyweight.

Rats fed for 30 days on a diet containing 20 per cent. casein and 0·3 per cent. cystine excreted in 24 hr. 29·1 per cent. of a dose of 4·8 mg. taurine-^{35}S per kg. bodyweight, but rats given only 8 per cent. casein excreted only 3·4 per cent. of the injected taurine. When the diet with 8 per cent. casein was supplemented with 50 mg. cysteic acid injected intraperitoneally daily for 3 days before the taurine was given, excretion of taurine rose to 10·8 per cent. With the 20 per cent. casein diet, 5·0 per cent. cholesterol given for 30 days reduced excretion of injected taurine to 18·8 per cent., and bromobenzene injected at 400 mg. per kg. bodyweight for 3 days similarly reduced excretion of taurine to 18·3 per cent. Weanling rats given a diet with 12 per cent. casein excreted 2·8 per cent. of the injected taurine when no cystine was included in the diet, but 14·5 per cent. when the diet contained 0·3 per cent. cystine.

The distribution of ^{35}S in the tissues was studied in some of the rats 24 hr. after injection of taurine. Adult rats given the 8 per cent. casein diet incorporated almost twice as much injected taurine-^{35}S into liver and muscle as did rats given 20 per cent. casein and 0·3 per cent. cystine. Weanling rats given 12 per cent. casein incorporated less ^{35}S into liver and muscle when they had had cystine than when they had not. There was never measurable ^{35}S activity in cystine isolated from protein hydrolysates. In 2 rats protein-free extracts were prepared from kidney and liver and concentrated for column chromatography, which revealed most of the ^{35}S still in taurine.—D. Duncan.

FISHER, H., SALANDER, R. C. and TAYLOR, M. W. **Growth and creatine biosynthesis in the chick as affected by the amino acid deficiencies of casein.** *J. Nutrition*, 1956, **58,** 459–470. [Dept. Poultry Husb., Rutgers Univ., New Brunswick, N.J.]

A basal ration of casein 25, maize oil 3, fibre 3, salt mixture 5·34, choline chloride 0·2 and cellulose 63·36 parts with vitamins was prepared. At the expense of cellulose, additions were made of, per cent., arginine 1, glycine 2, methionine 0·3, singly, in pairs or all three, or of creatine hydrate 0·8. These diets were given to chickens for 4 weeks from hatching. There were 2 control groups, one having the basal diet alone, the other a practical starter ration. There were 20 birds of each sex in each group. Weight was recorded and birds were killed at intervals of 4 days for estimation of creatinine in leg muscle. Data were analysed statistically.

Of the effects of amino acids given singly, in increasing rate of growth over that on the basal diet, only that of arginine was significant; in pairs they did better only when arginine was present and all 3 were no better than arginine and glycine. With the combination of arginine and glycine rate of growth was equal to that on the practical diet.

With all diets the level of creatine in muscle rose linearly with age over the 4-week period. In the groups given arginine and glycine, all 3 amino acids, creatine or the practical ration the rate of increase was greater than in the 6 other groups.

FINLAYSON, J. S. and BAUMANN, C. A. **Role of urea in rat proteinuria.** *Amer. J. Physiol.*, 1956, **184,** 469–472. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Male rats were given a basal diet of extracted casein 12, salts 4, maize oil 5, cystine 0·2 and glucose monohydrate (cerelose) to 100 per cent., with vitamins A, D, E, K and those of the B group, either to appetite or for 2 hr. daily. Variations in the diet were made at the expense of the carbohydrate. Blood and urine were collected for analysis; a simplified method for the routine estimation of protein in rat urine by centrifuging is presented.

When urea was given to appetite it increased the output of protein in the urine, but the increase was usually less than when the same amount of N was given as casein. Urea given for 2 hr. daily produced a rapid increase in protein output which, for the rest of the day, followed neither the blood urea nor the intake of water. A mixture of amino acids, prepared to resemble the components of casein, increased protein output to the same extent as the same amount of N in urea, but less than the equivalent high-protein diet.—G. F. Garton.

LASCH, H. G. and SCHIMPF, K. Blutgerinnung und alimentäre Fettbelastung. [**Blood clotting and administration of dietary fat.**] *Deutsch. Arch. klin. Med.*, 1956, **203,** 146–151. [Med. Klin., Univ. Heidelberg.]

In 10 healthy subjects given 70 g. butter by mouth clotting time of blood fell and the effect reached its maximum in from 120 to 150 min. after the test meal; there was visible lipaemia, but no relation between clotting time and degree of lipaemia. Recalcification time was reduced and there was a parallel increase in prothrombin and in Factor VII, a decrease in antithrombin III and IV, and an increase in thrombokinase activity, which reached its maximum about 150 min. after the test dose. The influence of dietary fat on clotting time is discussed in relation to the prophylaxis and treatment of thrombosis with a diet low in fat.—L. Wills.

BRONTE-STEWART, B., ANTONIS, A., EALES, L. and BROCK, J. F. **Effects of feeding different fats on serum-cholesterol level.** *Lancet*, 1956, **270,** 521–526. [Clin. Nutrit. Unit, Dept. Med., Univ. Cape Town.]

Two European men with initially high serum cholesterol and 5 Bantu men and 1 Cape Coloured man with initially low serum cholesterol were given diets to which several fats and oils were added, one at a time, usually in 100-g. amounts. The basal diet of the 2 Europeans included 50 g. fat daily, mainly of animal origin, and the diet of the 6 non-Europeans had a low fat content. Two of the non-Europeans were maintained on a diet poor in protein, and the protein given to a third non-European varied in amount. The cholesterol concentrations of serum and of serum lipoproteins were studied; so was the cholesterol content of the faeces.

Butter, beef dripping, beef muscle, eggs and hydrogenated groundnut oil caused increases in serum cholesterol. Marine animal oils decreased serum cholesterol, so did sunflower seed oil and a highly unsaturated fatty acid fraction from pilchard oil. Olive oil and groundnut oil did not raise serum cholesterol. Changes in protein intake did not appear to affect serum cholesterol.

KINSELL, L. W., FRISKEY, R. W., MICHAELS, G. D. and BROWN, F. R. (Jr.) **Effect of a synthetic triglyceride on lipid metabolism.** *Amer. J. Clin. Nutrition*, 1956, **4,** 285–286. [Inst. Metabol. Res., Highland Alameda County Hosp., Oakland, Calif.]

One patient aged 51 who had multiple fractures was given a chemically constant diet in which a synthetic triglyceride was the source of dietary fat; its composition was oleic acid 74, palmitic acid 19, stearic acid 5 and linoleic acid 2 per cent. The linoleic acid intake was about 2 g. daily. There was a prompt and profound fall of plasma cholesterol during administration of the synthetic fat. When 10 g. cholesterol, emulsified in the diet, was given, plasma cholesterol rose slightly. When cholesterol was withdrawn plasma cholesterol and

phospholipins fell. When coconut oil was substituted for the synthetic fat plasma cholesterol and phospholipins rose progressively.

DRYDEN, L. P., FOLEY, J. B., GLEIS, P. F. and HARTMAN, A. M. **Experiments on the comparative nutritive value of butter and vegetable fats.** *J. Nutrition*, 1956, **58,** 189–201. [Dairy Husb. Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Beltsville, Md.]

Groups of weanling rats were fed to appetite for several weeks on diets containing 4·7, 16·0, 30·7 and 40·0 per cent. of butterfat or maize oil. Growth, as indicated by weight gains, increased with increasing proportions of butterfat in the diet; similar but smaller increases in growth rate were observed with increasing proportions of maize oil. But only at the higher fat levels were the weight gains greater with the diets containing butterfat than with the diets containing maize oil. No additional effect was found when linoleate was added to butterfat.

In similar experiments no difference in the growth rate of young rats was found when they were fed on diets containing summer or winter butterfat.

Further feeding trials with diets containing Sulfathalidine (phthalylsulphathiazole) showed that butterfat and margarine as 28 per cent. of the ration increased weight gains of weanling rats more than did a similar diet containing maize oil, though this effect was seen only during the initial 3 weeks of the 8-week experiment. The effect was not apparent in the absence of Sulfathalidine.

DI LUZIO, N. R. and ZILVERSMIT, D. B. **Effect of choline, heparin and aureomycin on fatty livers of dogs.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 338–341. [Dept. Physiol., Univ. Tennessee, Memphis.]

Healthy dogs were kept for 3 weeks on a choline-deficient diet consisting of lard 38, sucrose 44, casein 8, cod liver oil 3 and salt mixture 5 parts. Seven animals were given a daily supplement of 1 per cent. choline chloride, 8 animals received 0·5 g. aureomycin twice daily and 9 were injected intramuscularly twice daily with heparin at the rate of 2 mg. per kg. bodyweight. At the end of the experiments liver lipids were extracted and phospholipins, total cholesterol, and triglycerides plus cholesterol ester fatty acids, the last designated "triglyceride" fraction, were estimated. Some liver slices were incubated with radio-active phosphate with and without the addition of choline, and the extent of phospholipin synthesis in 1 hr. was measured.

Supplementation of the diet with choline or daily injections of heparin reduced the amounts of liver triglycerides, but increased amounts of liver triglycerides were found in dogs which had received aureomycin. Neither choline, heparin nor aureomycin affected the values for liver phospholipins and cholesterol. More ^{32}P-labelled phospholipins were formed by liver slices when choline was added to the incubation medium if the slices were derived from the livers of choline-deficient dogs, but choline had little or no effect if the slices were from animals which had received choline.—G. A. Garton.

HOCK, A., HUBER, G. and PILAR-DIETRICH, A. v. Chemische Veränderungen des Lebergewebes infolge alimentärer Schädigung und ihre Beeinflussung durch Leberextrakte. [**Chemical changes in liver tissue after damage by food and the effect of liver extract.**] *Hoppe-Seyler's Ztschr.*, 1956, **304,** 11–20. [Forschungslab. Zellfabrik, Waldhof.] English summary.

The experimental diet contained, per cent., casein 16, tocopherol-free lard 51, maize starch 30 and salt mixture 3, with vitamin B_1, riboflavin, pyridoxine, Ca pantothenate, nicotinamide, *p*-aminobenzoic acid, inositol, biotin, vitamin A and vitamin D. The 12 groups of rats, of both sexes, of mean weight initially 130 to 140 g., were fed for 60 days on a standard diet or the basal diet or the latter with different supplements. Groups contained from 13 to 64 rats. In 6 groups the supplement was a preparation of ox liver autolysed with yeast and then dried, or a fraction of this autolysate. At the end the rats were killed and their livers were analysed.

On the unsupplemented experimental diet the rats had fatty livers, with 60·8 per cent. fat in the dry matter. The deoxyribonucleic acid (DNA) content was 20 to 30 per cent. below that on the standard diet, but the ribonucleic acid (RNA) content was normal. Supplements of liver autolysate or fractions soluble in 60 per cent. methanol reduced the amount of fat almost to normal, failed to prevent the fall of DNA, and increased RNA. Subfractions of the methanol extract were ineffective; so was yeast extract. Folic acid, vitamin B_{12}, choline, methionine and cysteine in amounts equal to or exceeding those in the liver

autolysate were ineffective, so the value of the autolysate is not attributed to these substances. None of them prevented the low DNA content caused by the diet or raised RNA.—D. Duncan.

HORN, R. G., BLOOD, F. R. and CONIGLIO, J. G. **Incorporation of C^{14}-acetate into intestinal fatty acids of rats with cannulated bile ducts.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 258–260. [Dept. Biochem., Sch. Med., Vanderbilt Univ., Nashville, Tenn.]

Five pairs of adult male rats were used; one animal of each pair had its bile duct cannulated, the other a sham operation. The rats were each given an intraperitoneal injection of ^{14}C-carboxyl acetate. Two pairs were killed 30 min. after the injections and the other 3 pairs 4½ hr. later; ^{14}C was estimated in samples of bile collected during the experiment from the latter animals. When the rats were killed the liver, bile and combined contents of caecum and intestine were taken for estimation of total fatty acids.

Cannulation of the bile duct did not impair the ability of intestinal contents to accumulate fatty acids labelled with ^{14}C. Total radio-activity of bile fatty acids was only 5 to 16 per cent. of that of the intestinal fatty acids. The intestinal fatty acids of cannulated rats had a greater specific radio-activity than those of sham-operated controls.

BRICE, E. G. and OKEY, R. (with STONE, M. M.) **The effect of fat intake on incorporation of acetate-2-C^{14} into liver lipide and expired carbon dioxide.** *J. Biol. Chem.*, 1956, **218,** 107–114. [Dept. Home Econ., Univ. California, Berkeley.]

Littermate male rats were fed on diets with 5 or 40 per cent. fat and equal in protein and salt per 100 Cal. One group were given the low-fat diet to appetite, the second group had the high-fat diet in quantities isocaloric with those eaten by the first group, and the third group had the high fat diet to appetite. After 3 weeks, acetate-2-^{14}C was injected intraperitoneally and respired CO_2 was collected. The rats were then killed and the radio-activity of cholesterol and fatty acids from liver was estimated.

A large proportion of the injected radio-activity was eliminated as CO_2 during the first hour after injection, but then the specific activity of the expired CO_2 dropped sharply and remained uniformly low for 24 hr. In the first hour the specific activity of the CO_2 was significantly higher in animals fed on the high-fat diet. The total output of CO_2 was apparently not affected by the fat intake, but the rats given the diet rich in fat eliminated more $^{14}CO_2$ in 12 hr. It is concluded that a high-fat diet results in increased oxidation of acetate, possibly with increased formation of acetate from fatty acids.

The livers of rats on the high-fat diet had a higher fat content, but the specific activity of the liver fatty acids was greater in the rats given the low-fat diet.—A. K. Lough.

SILIDES, D. J. and MAYER, J. **Effect of hormonal and dietary treatments on lipogenesis from acetate in hereditarily obese hyperglycemic mice.** *Experientia*, 1956, **12,** 66–67. [Dept. Nutrit., Harvard Univ. Sch. Pub. Health, Boston.] German summary.

Hereditarily obese hyperglycaemic mice and non-obese littermates were caged individually and fed on Purina chow or on a high-fat diet. After an 18-hr. fast each mouse received intraperitoneally acetate carboxyl-^{14}C, preceded in different experiments by injections of insulin, insulin plus glucose, growth hormone or glucagon. The mice were killed 30 min. after the injection of acetate for estimation of the radio-activity of the fatty acids of liver and of carcase (defined as body lipids minus liver lipids). In experiments with growth hormone the animals were killed 3 or 12 hr. after the injection of acetate.

Insulin considerably decreased formation of fat from acetate in both obese and non-obese mice. Growth hormone decreased lipogenesis in obese mice, but significantly increased fat synthesis in non-obese animals; the effect of glucagon was similar. Depressed lipogenesis from acetate was found in obese and non-obese animals which had had the high-fat diet.—G. A. Garton.

CLARK, R. and MALAN, J. R. **Alterations in the blood sugar and ketone levels caused by dosing acetate, propionate and butyrate into the rumen of the sheep.** *Onderstepoort J. Vet. Res.*, 1956, **27,** 101–109. [Onderstepoort Lab.]

Solutions of sodium acetate, propionate or butyrate alone or in combinations were given in 0·5 g. molar doses in a litre of water into the rumen of sheep. Propionate alone or in combination was the only salt that caused a rise in blood sugar. Butyrate by itself usually depressed blood sugar, but sometimes increased it. Acetate had little effect. Butyrate increased blood ketones, especially β-hydroxybutyrate, acetate caused a small and somewhat delayed rise in total blood ketones, but propionate had no effect. Butyrate also depressed circulating blood fat. When 5 mg. β-hydroxybutyric acid was injected blood sugar fell. Conversion of acetoacetic acid to β-hydroxybutyric acid was found in sheep's blood *in vitro*.

REISER, R. and REDDY, H. G. R. **The hydrogenation of dietary unsaturated fatty acids by the ruminant.** *J. Amer. Oil Chem. Soc.*, 1956, **33,** 155–156. [Dept. Biochem. Nutrit., Texas Agric. Exp. Stat., College Station.]

Two adult goats were fed for 11 weeks on a diet of alfalfa meal with 10 per cent. cottonseed oil and another 2 for the same time on alfalfa meal with 10 per cent. linseed oil. Six hours after the last meal the goats were killed and the fatty acid compositions of samples of back fat and of the contents of the rumen, abomasum and caecum were compared with that of the feed.

The high levels of linoleic and linolenic acids in the diet were reduced to low levels in the rumen lipids, with concomitant increases in the amounts of saturated fatty acids ; the proportion of oleic acid in the rumen lipids was greater than in linseed oil and in one animal greater than in cottonseed oil.

The back fat of the animals given cottonseed oil contained more saturated fatty acids and less oleic acid than that of goats given linseed oil.

KANEDA, T., SAKAI, H. and ISHII, S. **Nutritive value or toxicity of highly unsaturated fatty acids. 2.** *J. Biochem., Tokyo*, 1955, **42,** 561–573. [Tokai Reg. Fish. Lab., Tokyo.]

Weanling rats, fed on a fat-deficient diet until they attained a constant bodyweight, were then given from 0·2 to 0·5 g. daily for 30 days of the lipid to be tested.

Auto-oxidised esters of linseed oil and some fractions prepared from them were toxic, but polymerised highly unsaturated fatty acids and peroxide-free products from auto-oxidised, unsaturated fatty acids were not, and had nutritive value. The liver and muscle of rats fed on auto-oxidised, unsaturated fatty acids contained large amounts of peroxide. The LD_{50} of total peroxide oxygen per kg. bodyweight for mice was calculated as being about 278 mg.

It is concluded that the most toxic product of auto-oxidised, unsaturated fatty acids is peroxide, which is produced at the beginning of auto-oxidation, and that its toxicity is due to injury to tissues.—M. H. Pierce.

SELLERS, E. A. and YOU, R. W. **Deposition of fat in coronary arteries after exposure to cold.** *Brit. Med. J.*, 1956, i, 815–819. [Dept. Physiol., Univ. Toronto.]

In rats fed on stock diet and kept in a cold room at 1° to 3° C. for 10 to 18 months, blood pressure measured directly under light anaesthesia was within the normal range. Histological study of 29 of the rats in the cold room and of 27 controls kept at 22° ± 2° C. showed that none of the controls, but more than half of the cold room rats, showed fatty infiltration of the coronary vessels. Kidneys, liver and adrenals were significantly heavier in rats exposed to cold, and kidney damage was almost always found in the exposed rats. Serum total lipids and free and bound cholesterol were significantly increased after a year or more in the cold.

Deposition of fat in the coronary vessels occurred in rats fed on a high-fat, high-cholesterol diet with 0·5 per cent. choline and exposed to cold for 6 weeks, but not when choline was omitted from the diet. Myocardial lesions occurred whether or not choline was present in the diet. At room temperature deposition of fat in the coronary vessels occurred in rats which failed to survive on a diet deficient in choline. In only one of the rats receiving choline at room temperature was lipid present in a coronary artery.—F. C. Aitken.

THOMAS, W. A., O'NEAL, R. M. and LEE, K. T. **Thromboembolism, pulmonary arteriosclerosis, and fatty meals ; an experimental study of the effect of intermittent fatty meals on thromboembolic-induced pulmonary arteriosclerosis in rabbits.** *Arch. Pathol.*, 1956, **61,** 380–389. [Dept. Pathol., Sch. Med., Washington Univ., St. Louis, Mo.]

Three groups of rabbits were given intravenous injections of blood clot weekly for 6 weeks. One

group was given a feed of butter, another a feed of margarine and the third water through a stomach tube after each injection. Fibrous intimal thickening in the pulmonary arteries was present in all groups, but the frequency and severity of lesions were significantly greater in animals receiving fat. Small but definite quantities of fat were present in lesions in the pulmonary artery in almost half of the animals in all groups.—F. C. Aitken.

BEVERIDGE, J. M. R., CONNELL, W. F. and MAYER, G. A. **Dietary factors affecting the level of plasma cholesterol in humans : the role of fat.** *Canad. J. Biochem. Physiol.*, 1956, **34,** 441–455. [Dept. Biochem., Fac. Med., Queen's Univ., Kingston, Ont.]

Three experiments were performed on male medical students and staff. In each study all the subjects had the same homogeneous diet for 8 days, after which they were divided into 5 groups comparable on the basis of blood cholesterol. One group was continued on the original diet for another 8 days ; the other 4 groups were given diets varying in the level and nature of the fat content. Protein supplied 16·9 per cent. of the total energy in all the experimental rations. Cholesterol was estimated in samples of heparinised plasma ; all blood samples were obtained before breakfast.

In the first experiment the 37 subjects ate a diet in which 58·5 per cent. of the energy was from maize oil ; during the initial 8-day period the average of the individual decreases in plasma cholesterol was 32 per cent. The group which continued on maize oil had a further, not significant decrease during the second 8-day period. The other 4 groups, given diets high in beef dripping, chicken fat, lard and butter, respectively, showed average individual increases in plasma cholesterol of 11·7, 12·7, 15·4 and 28·8 per cent.

In the second experiment the 49 subjects ate a fat-free diet for 8 days ; the average fall in plasma cholesterol was 22·2 per cent. Those continuing on the fat-free diet showed little further change, those given diets providing 20 and 60 per cent. of the energy as maize oil showed falls in plasma cholesterol of 6·9 and 15·2 per cent. and those given diets providing 20 and 60 per cent. of the energy as butterfat showed increases of 6·6 and 21·7 per cent.

In the third experiment the 36 subjects ate a diet in which butterfat provided 60 per cent. of the energy during the 8-day initial period. The plasma cholesterol remained almost constant, and did not change significantly in the subjects who continued on the same diet for a further 8 days. The composition of the fat in the diets of the remaining 4 groups, in terms of percentage of energy derived from butterfat and maize oil, respectively, was 45 : 15, 30 : 30, 15 : 45 and 0 : 60. The average decreases in plasma cholesterol were 3·9, 15·9, 27·1 and 32·0 per cent. Except for the smallest, all the changes were highly significant.—G. F. Garton.

ROEN, P. B. **Reduction of serum lipids by dietary management. Report on 50 cases.** *Geriatrics*, 1956, **11,** 200–202. [Clin. Study Arteriosclerosis, Hollywood Presbyterian Hosp., Los Angeles, Calif.]

Fifty patients with total serum cholesterol levels of 210 to 600 mg. per 100 ml. were given a low-fat diet for 13 to 72 months. The average drop in serum cholesterol was 146 mg., ranging from 60 mg. in the patient with an initial level of 210 mg. to 345 mg. in the patient with an initial level of 600 mg. During the study patients maintained on the average 82 per cent. of their maximum drop in serum cholesterol.—F. C. Aitken.

JOYNER, C. (Jr.) and KUO, P. T. **The effect of sitosterol administration upon the serum cholesterol level and lipoprotein pattern.** *Amer. J. Med. Sci.*, 1955, **230,** 636–647 ; 674. [Edward B. Robinette Found., Philadelphia, Pa.]

When β-sitosterol was given by mouth to hospital patients on unrestricted diets the serum cholesterol fell, whatever the initial value ; no significant change in bodyweight occurred and no untoward side effect was apparent. The smallest effective dose of β-sitosterol was > 10 g. daily for 4 weeks. The β-sitosterol also produced lower serum cholesterol in 2 patients on low-fat diet.

Electrophoretic studies of serum lipoproteins showed that the β-sitosterol brought about changes in the β-lipoproteins, but not in the α-lipoprotein fraction.—G. A. Garton.

CANTONE, A. Azione antilipemica di un preparato mucinico dalla mucosa gastrica di maiale in conigli trattati con dieta ipercolesterolica. **[Effect of a mucin preparation from pig's gastric mucosa to depress blood lipids of rabbits given a diet high in cholesterol.]** *Bol. Soc. ital. Biol. sper.*, 1955, **31,** 838–840. [Ist. C. Erba Ric. Terap., Lab. Biol., Milan.]

Rabbits weighing about 2½ kg. were given for 2 weeks a diet without lipids. Two groups of 5 were then given for 6 weeks a normal diet with cholesterol daily by stomach tube ; one group received in addition, also by stomach tube, the mucin fraction obtained by acetone precipitation

of an acid extract from pig's gastric mucosa. Every week, fatty acids and free and total cholesterol were estimated in the blood plasma. All the mean values were lower for the group given the mucin fraction, and the differences were significant.—E. M. Hume.

SWELL, L., BOITER, T. A., FIELD, H. (Jr.) and TREADWELL, C. R. **The absorption of plant sterols and their effect on serum and liver sterol levels.** *J. Nutrition*, 1956, **58**, 385–398. [Gen. Med. Res., Veterans Admin. Centre, Martinsburg, W. Va.]

Groups of rats were fed for 21 days on synthetic diets containing oleic acid 25, Na taurocholate 1 and soya bean sterols 2 per cent., together or in different combinations. The sterol intake was measured and faecal excretion was estimated.

When no fat was present in the diet soya bean sterols were recovered almost quantitatively from the faeces. When Na taurocholate or oleic acid was added to the diet 15·7 per cent. of dietary soya bean sterol was absorbed. When both oleic acid and taurocholate were present about 23 per cent. of the ingested sterol was absorbed.

Serum sterol values increased in all groups given the diets containing soya bean sterols with oleic acid or oleic acid and taurocholate, though there was no increase in the amount of sterols in the liver. No plant sterol could be detected chromatographically in the liver or serum sterols of animals given soya bean sterols. It is suggested that plant sterols were converted to cholic acid, cholesterol or a cholesterol intermediate in the intestine or liver.—G. A. Garton.

OKEY, R. and LYMAN, M. M. **Protein intake and liver cholesterol : effects of age and growth of the test animal.** *J. Nutrition*, 1956, **58**, 471–482. [Dept. Home Econ., Univ. California, Berkeley.]

Groups of rats were fed from weaning on isocaloric diets containing 10, 15 or 30 per cent. protein, as a mixture of casein and egg albumin, and 1 per cent. cholesterol, together with fat, sucrose, salts and vitamins; control animals received the same diets without cholesterol. Animals in each group were killed after from 3 to 12 weeks on the diets for estimation of total liver lipids and liver cholesterol.

On the cholesterol-free diets some decrease in liver cholesterol was found with increasing proportions of dietary protein, but no significant change with age.

The greatest accumulation of liver cholesterol in the groups given cholesterol was found in those given the diet containing 15 per cent. protein for 7 to 8 weeks ; at 10 weeks liver cholesterol showed a decrease. Animals given the diet containing 30 per cent. protein showed the highest liver cholesterol values 3 weeks after weaning ; subsequently the values continued to decrease during the period of rapid growth. When the diet contained only 10 per cent. protein, growth rate of the rats was impaired and, though total liver fat was more than in animals given 15 per cent. protein, liver cholesterol did not accumulate proportionately G. A. Garton.

DAM, H., KRISTENSEN, G., NIELSEN, G. K., PRANGE, I. and SØNDERGAARD, E. **Influence of various levels of peanut oil and cholesterol on cholesterol and polyenoic acids in tissues of chicks.** *Acta physiol. scand.*, 1956, **36**, 319–328. [Dept. Biochem., Polytec. Inst., Copenhagen.]

Sixteen groups each of 9 chickens were fed for 4 weeks from the 14th day after hatching on diets containing no groundnut oil, or 3, 10 or 20 per cent. without cholesterol, or with 0·1, 0·3 or 1·0 per cent. cholesterol. Cholesterol was then estimated in liver, heart, aorta, lungs, brain, spleen and adipose tissue, and polyethenoid fatty acids were estimated in the lipids of all these organs except spleen. The cholesterol content of liver, spleen, heart, aorta and lungs increased after both cholesterol and groundnut oil had been given. The greatest deposition of cholesterol in liver occurred when the diet contained 1 per cent. cholesterol and 20 per cent. groundnut oil. Liver cholesterol values on diets containing 0·1 per cent. or no cholesterol were greatest when the diet contained no groundnut oil. No change was found in the cholesterol content of brain.

Variations in the intake of cholesterol had little or no influence on the polyethenoid fatty acid content of the organs. With increasing amounts of groundnut oil, the di- and tetraethenoid fatty acid content of the lipids of liver, heart and lungs increased and the triethenoid fatty acid content decreased ; almost no change in the small amounts of penta- and hexaethenoid fatty acids was found. In brain, the triethenoid fatty acid content decreased, but the content of other polyethenoid fatty acids did not change. In adipose tissue the amount of diethenoid fatty acids increased ; no change in the amounts of the more unsaturated acids was found.—G. A. Garton.

PEDDIE, G. H., SPURR, C. L. and HOWARD, J. M. **Studies of calcium metabolism following surgical trauma.** *Ann. Surg.*, 1956, **143,** 452–458. [Dept. Surg., Baylor Univ. Coll. Med., Houston, Tex.]

The results of studies of Ca and P balances, serum Ca and P and pulse rate before and after operation in 5 patients are charted. One patient showed pronounced tachycardia which coincided with a fall of serum Ca of 3·7 mg. per cent. immediately after operation. This patient differed from the others in that the drop in serum Ca was sharper and the post-operative negative Ca balance was smaller. Data on Na, Cl, K and N balance, serum K and excretion of 17-hydroxycorticosteroids in this patient are charted also. The tachycardia and drop in serum Ca coincided with a rise in serum K. Balances of Na and Cl were positive and balances of K and N were negative after operation. There was a sharp, transient rise in excretion of 17-hydroxycorticosteroids in urine. Serum Ca rose to normal on the second day after operation and serum K and pulse rate began to fall. In this patient, as in the others, Ca balance became positive when food was given by mouth.—F. C. Aitken.

DAVIES, H. E. F., JEPSON, R. P. and BLACK, D. A. K. **Some metabolic sequels of gastric surgery in patients with and without pyloric stenosis.** *Clin. Sci.*, 1956, **15,** 61–79. [Dept. Med., Univ. Manchester.]

Balances of Na, K and Cl and sometimes also of N, Ca, P and Mg were studied in 23 patients, 10 without pyloric stenosis and 13 with stenosis, 10 of whom had clinical signs and in the other 3 of whom it was found at operation. The diet was mainly milk with, for some, supplements of K and Na. Complete data are tabulated for the later patients, some having already been published (Black and Jepson, *Quart. J. Med.*, 1954, **23,** 267), and there was calculated for each ion the range within which 95 per cent. of values for retention might be expected normally to fall in patients who were without stenosis and who had undergone partial gastrectomy. Where, in a patient who had had stenosis, the value for an ion was greater than these limits, it was deduced that depletion had occurred. This criterion indicated that, of the 10 patients with clinical signs, 3 were depleted of Na, 5 of K and 4 of Cl ; of the 3 with no clinical sign, 1 was depleted of K. For the smaller numbers in whom the other elements were studied, 5 without and 6 with pyloric stenosis, the results showed that none was depleted of N or Ca ; there were doubts about the findings for P and Mg.

The relation between balances of Na, K and Cl and the occurrence of alkalosis is discussed.

LEVEY, S., ABBOTT, W. E., KRIEGER, H. and DAVIS, J. H. **Metabolic alterations in surgical patients. 8. Studies involving iron and magnesium metabolism in patients with gastrointestinal drainage.** *J. Lab. Clin. Med.*, 1956, **47,** 437–443. [Dept. Surg., Sch. Med., Western Reserve Univ., Cleveland, Ohio.]

For part 3 see Abst. 5217, Vol. 25.

8. Three of the 4 patients had pyloric obstruction requiring gastric suction and, subsequently, operation. The fourth had intestinal ileus which responded to intestinal intubation without operation. All were fed intravenously. Balance studies were made on several days before and after operation in the first 3 patients and on 6 days in the fourth. In general patients were in positive Fe balance throughout and, except for the fourth patient and for one of the others after operation, Fe loss in gastric drainage exceeded the combined loss of Fe in urine and faeces. Two patients were in positive Mg balance throughout. In the others Mg balance was sometimes negative, sometimes positive, depending apparently on the intake. An intake of over 100 mg. Mg daily was associated with a positive balance.

F. C. Aitken.

CALCIUM AND PHOSPHORUS AND STRONTIUM

4731

MORATA GARCÍA, F., ESPINAR LAFUENTE, M. and ORTIZ DE LANDÁZURI, E. Efecto de la sobrecarga de calcio sobre el metabolismo del fosforo en normales y en circunstancias patologicas. [**Effect of a test dose of calcium on the metabolism of phosphorus in normal and pathological conditions.**] *Rev. clín. española*, 1956, **60,** 87–94. [Clín. Méd., Univ. Granada.] English, German and French summaries.

The calcium load test consisted in administration by intravenous drip lasting 4 hr. of 1 litre of 0·9 per cent. saline with 15 mg. ionic Ca or 168 mg. calcium gluconate per kg. bodyweight. Blood Ca and P were studied, and excretions of Ca and P were followed in 3 periods, up to 4 hr., 4 to 6 hr. and 6 to 24 hr. after the beginning of the infusion. Inulin clearance was estimated also. For control observations the subjects received on the day before the Ca load a similar test, but with saline

alone. The subjects were kept at rest. There were 7 normal subjects, 1 with idiopathic hypoparathyroidism and 3 with renal sclerosis.

In normal subjects the Ca load produced in the first 6 hr. much greater diuresis than saline alone, but the amount of urine secreted in 24 hr. was similar. Serum Ca did not change with saline injection, but during infusion of Ca it rose from the mean initial value of 10·6 mg. per 100 ml. to 14, falling in the next 2 hr. to 11·9 and after 24 hr. to 10·8. Serum inorganic P also rose during the infusion from 3·8 to 4·7 mg. per 100 ml. and then fell to 4·6 at 6 hr. and 3·1 at 24 hr. Excretion of Ca in the urine was 0·19 mg. per min. on the control day and 0·47 mg. per min. when Ca was given, and 403 mg. of the 770 mg. infused was excreted. Excretion of P was 1·10 mg. per min. on the control day and fell to 0·83 when Ca was given; during the infusion and in the next 2 hr. the rate of excretion rose, but from 6 to 24 hr. it was considerably below that on the control day. The glomerular filtration rate was on the average 117 ml. per min. in the first 6 hr. when saline was given, 130 ml. per min. in the first 4 hr. and 121 ml. in the next 2 with Ca.

In the subject with parathyroid insufficiency serum Ca initially and after 4, 6 and 24 hr. on the day when Ca was given was 7·8, 11·8, 10·6 and 8·6 mg. per 100 ml. and serum P 5·8, 6, 6·55 and 4·99 mg. per 100 ml. Output in urine was 0·06 mg. Ca per min. on the control day and 0·28 mg. when Ca was given; 316 mg. of the 750 mg. infused was recovered. Excretion of P was increased from 0·59 to 0·81 mg. per min. on the day when Ca was given, but was low in the period from 4 to 6 hr.

In the 3 subjects with renal sclerosis the values for serum Ca on the day of experiment were, respectively, 8·7, 12·4, 12·5 and 9·5 mg. per 100 ml.; 9·7, 13·8, 13·4 and 16·6; and 10·2, 15·4, 20·2 and 15·6. Corresponding values for P were 7·75, 7·79, 7·85 and 7·77; 4·9, 5·5, 5·87 and 5·55; and 2·7, 2·5, 2·1 and 2·2 mg. per 100 ml. Thus the behaviour of serum P was particularly variable. Ca excretion in the urine rose so slightly after the test load that only 6 per cent. of the dose was recovered in 24 hr. Excretion of P increased in the first subject and decreased in the other 2. Glomerular filtration rate was always low, but tended to rise when Ca was given.

The significance of the results is discussed.

D. Duncan.

NORDIN, B. E. C. and FRASER, R. **A calcium-infusion test. 1. Urinary excretion data for recognition of osteomalacia.**

FINLAY, J. M., NORDIN, B. E. C. and FRASER, R. **2. "Four-hr. skeletal retention" data for recognition of osteoporosis.** *Lancet*, 1956, **270**, 823 – 826; 826 – 830. [Hammersmith Hosp., London.]

1. Patients to be tested are kept on a low-calcium diet, with 100 to 150 mg. Ca and 500 to 700 mg. P daily, for 3 days before and during the test. Urine is collected from 6 a.m. on the third day to 6 a.m. on the fourth day and then in 4-hr. portions till 6 a.m. on the fifth day. Calcium gluconate, 15 mg. Ca per kg. bodyweight in 500 ml. physiological saline, is given between 10 a.m. and 2 p.m. on the fourth day. Blood is taken at the beginning and end of the infusion and at 6 p.m. on that day and 10 a.m. next day.

Results are presented for 98 subjects: 21 apparently normal, 12 with osteomalacia and steatorrhoea, 17 with steatorrhoea but no clear evidence of osteomalacia, 18 with osteoporosis and 30 with disorders likely to involve disease of the bone. All those with steatorrhoea excreted less excess Ca in 12 hr. from the commencement of the infusion than did the normal subjects; those with osteoporosis excreted normal or only occasionally greater than normal amounts. Of the 30 possibles, 10 excreted less than normal, 6 for known reasons.

2. Since the 12 hr. excretion of Ca failed to distinguish patients with osteoporosis from the normal subjects, excess Ca circulating in the extracellular space was computed and "4-hr. skeletal retention" derived by subtracting from the amount infused that which could be accounted for in extracellular fluid at the end of the infusion or in urine representing the 4 hr. infusion. The extravascular fluid was assumed to be 15 and the intravascular fluid 5 per cent. of bodyweight and the level of Ca in extracellular fluid to be that in an ultrafiltrate of serum.

In 10 normal subjects the 4-hr. skeletal retention was between 48·6 and 61·8, mean 55·2 per cent. of that infused; 8 patients with osteomalacia retained more, 5 of 7 with steatorrhoea without obvious bone disorder retained more, and 11 out of 15 with osteoporosis retained less than the normal subjects. These and 14 patients with miscellaneous disorders are discussed. Since in osteoporosis Ca in skeleton at 4 hr. and in urine at 12 hr. did not represent as high a proportion of the whole as in normal subjects, either skeletal deposition was slow or Ca was lost in faeces. The test is believed to be applicable to diagnosis of osteoporosis.

In an appendix a method for calculating ultrafiltrable Ca, instead of estimating it, is described and shown to give results in good agreement with measurements in almost all patients.—I. Leitch.

4733

MORGAN, H. G., MITCHELL, R. G., STOWERS, J. M. and THOMSON, J. **Metabolic studies on two infants with idiopathic hypercalcaemia.** *Lancet*,

1956, **270,** 925–931. [Dept. Pathol., Univ. St. Andrews.]

When intakes of Ca and vitamin D were restricted and 25 mg. cortisone was given daily by mouth, Ca in blood fell and there was clinical improvement in both infants. Before treatment, absorption of Ca and P was high. Cortisone more than doubled excretion of Ca and P in faeces, and reduced the amounts retained. Disodium ethylenediamine-tetra-acetic acid given before cortisone to one infant reduced blood Ca but was toxic. Diet histories of both infants showed substantial amounts of vitamin D from cod liver oil and fortified foods. Excessive intake of or hypersensitivity to vitamin D are possible causes of hypercalcaemia in infants, and it is suggested that re-assessment of the degree of fortification of infant foods is needed.—F. C. Aitken.

4734

WOODS, K. R. and ARMSTRONG, W. D. **Action of parathyroid extracts on stable bone mineral using radiocalcium as tracer.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 255–258. [Dept. Physiol. Chem., Med. Sch., Univ. Minnesota, Minneapolis.]

Seventy-two days after a group of 23 rats had received injections of radio-active calcium, one leg was amputated and the specific activity of Ca in the epiphyses and diaphyses of the humerus was estimated. At this stage daily injections of parathyroid hormone, or of saline in control animals, were begun, and the rats were killed up to 13 days after the beginning of hormone treatment. After death specific activities of the remaining humerus from each animal were estimated. During the 13 days of treatment Ca was estimated in urine.

There was no difference between the specific activities of epiphyses and diaphyses of any humerus and no change in specific activity of the bone Ca of either control or treated animals during the 13 days of injection. But parathyroid hormone caused a large increase in excretion of radio-active Ca, showing that parathyroid hormone was able to release Ca from the stable fraction of bone salt. The absence of difference between the specific activities of control and treated rats indicated that parathyroid hormone affects the labile and stable fractions of bone equally.—R. Hill.

TARJÁN, R. Einfluss der Ernährung auf das Knochensystem. 3. Experimentelle Untersuchung der Zitronensäurewirkung. [**Effect of nutrition on the bones. 3. Experimental study of the effect of citric acid.**] *Acta physiol. hung.*, 1955, **8,** 119–126. [Inst. Ernährungswiss., Budapest.] Russian summary.

3. Methods and basal diet have been described earlier (Tarján *et al.*, *Acta physiol. hung.*, 1954, **5,** 313 ; 463). The diet was normal in protein and vitamins ; P was held constant and Ca was varied. There were 4 groups of 12 male rats, 4 weeks old. Groups 1 and 2 had 0·28 per cent. Ca and groups 3 and 4 0·96 per cent. Ca, with Ca : P ratios of 0·72 and 2·5, respectively ; rats in groups 2 and 4 had 1 g. cod liver oil weekly [1 ml. in table 1], those in group 1 had 0·56 per cent. sodium citrate mixed with the feed daily and those in group 3, 0·90 per cent. The animals were weighed and X-rayed weekly ; half were killed in the 11th week, the rest in the 17th week.

There was little difference in weight gain, though after the 10th week the rats given citrate did slightly better than those given cod liver oil. At both 11 and 17 weeks the femurs of those given citrate were mechanically stronger, both absolutely and relatively to bodyweight, and contained more ash, except for the high-Ca group at 11 weeks ; there was little difference in the percentage of Ca in the ash.

It was concluded that the regular consumption of an amount of citric acid roughly equivalent to the Ca content of the diet gave satisfactory growth even when the diet was mildly rachitogenic.

There is a brief summary of the literature.

SATO, T. **Effects of parotid gland extract (Parotin) upon the calcification of rabbit dentine and bone.** *Gunma J. Med. Sci.*, 1955, **4,** 333–340. [Dept. Maxillo-Stomatol., Sch. Med., Gunma Univ., Maebashi.]

A purified extract of parotid gland given by vein to rabbits was found to have effects similar to those produced by the crude extract (see Abst. 817, Vol. 24). A smaller amount, 1 mg., compared with 5 mg. per kg. bodyweight for the crude extract, accelerated calcification and growth of dentine and growth of bone.—D. Harvey.

4737

MATSUDA, N. **On effects of a submaxillary gland extract upon calcification figure of rabbit dentine and bone. 1. Effects of a submaxillary gland extract upon serum Ca and the formation of rabbit dentine and bone.** *Gunma J. Med. Sci.*, 1955, **4,** 317–324. [Dept. Maxillo-Stomatol., Sch. Med., Gunma Univ., Maebashi.]

1. The methods of study were those of Sato (Abst. 817, Vol. 24). With single injections into rabbits of the following amounts per kg. bodyweight given by vein the effects were : 10 mg., inhibition of calcification of dentine and fall in serum Ca ; 5 mg., temporary inhibition and later acceleration of calcification with rather less change in serum Ca ; 3, 1 or 0·5 mg., rate of calcification

increased with least change in serum Ca ; 0·3 mg., results inconsistent. With injection of 0·5 mg. repeated on each of 3 successive days growth and calcification of dentine and growth of bone were accelerated. With hypodermic injections, 5 mg. per kg. accelerated calcification. In animals from which parotid and submaxillary glands had been removed a smaller amount, 0·1 mg. per kg., by vein was effective.—D. Harvey.

4738

MATSUDA, N. **On the effect of an extract from saliva upon calcification and development of hard tissue.** *Gunma J. Med. Sci.*, 1956, **5,** 51–60. [Dept. Maxillo-stomatol., Sch. Med., Gunma Univ., Maebashi.]

Experiments similar to those in the preceding abstract were made with an extract from pooled human saliva. A single injection of the crude form, 0·5 mg. per kg. bodyweight given by vein to rabbits, accelerated rate of calcification but not rate of growth of dentine. With the purified form amounts of 5, 1·0 or 0·5 mg. per kg. increased the rate of calcification but with 30 mg. per kg. calcification was inhibited. When 0·3 mg. of the purified form was injected on each of 3 successive days, rates of formation of both dentine and bone were increased. Similar results were obtained with crude extracts prepared from saliva of cat, dog, ox and rabbit.—D. Harvey.

WEIDMANN, S. M. **Studies on the skeletal tissues. 4. The renewal of inorganic phosphate in bones of various species of small mammal as a function of time.** *Biochem. J.*, 1956, **62,** 593–601. [Biol. Res. Unit, Dent. Sch., Univ. Leeds.]

For part 3 see Abst. 4704, Vol. 23.

Radio-active phosphorus, 33 μC. per kg. bodyweight, was injected into mature rabbits, cats and rats, which were killed up to 30 days later for estimation of ^{32}P in different parts of the skeleton.

The uptake of ^{32}P by cortical and cancellous tissue of long bones was much more rapid in the rat and rabbit than in the cat, and slightly more rapid in the rat than in the rabbit. This was particularly evident during the first hours after injection. No decrease in the amount of ^{32}P was found during the 30 days of experiment except in the cancellous tissue of the rat.

Regional differences in activity of cortical bone were large ; the activity of inner layers was greatest and that of middle layers least. The differences became slowly smaller, indicating transference towards inner layers. This movement of ^{32}P was accompanied by a decrease in the activity of readily soluble phosphate from the inner layers of cortical bone.

In cancellous tissue ^{32}P became equally distributed between readily soluble and residual phosphate 9 days after injection.—R. Hill.

LAX, L. C., SIDLOFSKY, S. and WRENSHALL, G. A. **Compartmental contents and simultaneous transfer rates of phosphorus in the rat.** *J. Physiol.*, 1956, **132,** 1–19. [Banting and Best Dept. Med. Res., Univ. Toronto, Ont.]

Rats fasted for 24 hr. were given injections of ^{32}P and killed up to 410 min. later.

From the specific activities of separate body organs and tissues, calculations of phosphorus transfer between the tissues and the plasma pool were made. Values in μg. per min. ranged from 153·0 for bone and teeth to 0·24 for brain. The net amount of P within each organ or tissue was calculated also.—R. Hill.

MAGNESIUM

4741

HEGSTED, D. M., VITALE, J. J. and MCGRATH, H. **The effect of low temperature and dietary calcium upon magnesium requirement.** *J. Nutrition*, 1956, **58,** 175–188. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Growth studies were made on a total of 286 rats ; the number in a group varied from 4 to 10 in the different experiments. The variables were Mg intake, from 3 to 100 mg. per 100 g. diet, Ca content of the diet, 200, 600 or 1800 mg. per 100 g., and environmental temperature, either 55° $\pm$ 2° F. in the cold room or 78° $\pm$ 2° F. in the warm room. The animals received a diet of purified casein 20, glucose 71·5, maize oil 5, cod liver oil 1, salt mixture without Ca and Mg 2·25, cystine 0·25 and choline chloride 0·3 per cent. ; vitamins of the B group were added.

The amount of Mg required to promote equal gains in weight was about 4 times as much at the environmental temperature of 55° F. as at 78° F. Since the maximum rate of gain was less at the lower temperature, the difference in the amount required for maximum gain was less, 25 mg. per 100 g. diet at 78° F. and 50 mg. at 55° F. High Ca intakes were detrimental at low Mg intakes ; in some experiments high Ca intake apparently accentuated injury by cold.

Balance studies were made on 12 adult female rats given the diet containing 50 mg. Mg and 600 mg. Ca per 100 g. ; food intakes were estimated daily and urine and faeces were collected every 3 or 4 days. During the first week the rats were in the warm room ; they were then put in the cold room and collections were continued for 4 weeks. The data obtained showed that Mg balance was

primarily related to Mg intake and that the amount of Mg required to maintain balance was greater in the cold room.—G. F. Garton.

Ross, E. J. **Total exchangeable sodium in hypertensive patients.** *Clin. Sci.*, 1956, **15**, 81–91. [Med. Unit, University Coll. Hosp. Med. Sch., London, W.C.1.]

Total exchangeable Na was measured with ^{24}Na, total body water with antipyrine and extracellular water with thiosulphate in 10 adults with normal blood pressure and in 37 patients with high blood pressure, essential or considered to be of renal origin.

In some patients total exchangeable Na was within the normal range, in others it was well above normal. In 10 severely hypertensive patients with high total exchangeable Na, total body water and plasma Na were almost normal and most of the extra Na was intracellular or in bone.

When the patients were graded according to the severity of changes in the fundus, there was some positive correlation between high total exchangeable Na and the severity of the hypertension, but scatter was wide.

Two patients with malignant hypertension and initially high exchangeable Na had both adrenals removed. One patient responded with a return to normal of both blood pressure and exchangeable Na. The other failed to respond in either way.

In 3 patients whose Na intake was restricted and of whom 2 were given cation-exchange resins blood pressure fell, but there was little change in exchangeable Na.—D. Duncan.

Edelman, I. S. and Sweet, N. J. **Gastrointestinal water and electrolytes. 1. The equilibration of radiosodium in gastrointestinal contents and the proportion of exchangeable sodium (Na_e) in the gastrointestinal tract.**

Nadell, J., Sweet, N. J. and Edelman, I. S. **2. The equilibration of radiopotassium in gastrointestinal contents and the proportion of exchangeable potassium (K_e) in the gastrointestinal tract.** *J. Clin. Invest.*, 1956, **35**, 502–511; 512–521. [Dept. Med., Univ. California Sch. Med., San Francisco.]

1. Forty rabbits of both sexes were fed on stock pellets to appetite or starved for up to 44 hr. before death. Each received an intraperitoneal injection of 100 to 150 μC. $^{24}NaCl$ in isotonic NaCl at *p*H 7. Urine and faeces were collected for 20 to 26 hr. and the rabbits were then killed and the contents of the digestive tract were recovered from separate segments.

Total exchangeable Na was calculated to be $46{\cdot}0 \pm 2{\cdot}0$ m. equiv. per kg. bodyweight. Of this $14{\cdot}2 \pm 2{\cdot}4$ per cent. was in the digestive tract, $10{\cdot}2 \pm 2{\cdot}1$ per cent. of it in the proximal half of the large intestine. Equilibrium of ^{24}Na between the digestive tract and the body was complete within 24 hr. after injection. Fasting did not affect the results.

The contents of the digestive tract were collected after death from 13 human subjects without oedema or organic gastro-intestinal disease. The interval after death was from 6 to 22 hr., and was not found to be related to the amount of Na recovered. Of the total exchangeable Na calculated according to age, sex and bodyweight, on the average 1·6 per cent., 0·54 m. equiv. per kg. bodyweight, was found in the digestive tract. Almost half was in the small intestine. It cannot be assumed that these values would be found in life.

2. The plan of the study was similar to that described above; 44 rabbits received 250 to 350 μC. $^{42/43}KCl$ intraperitoneally.

Equilibrium between the specific activities of digestive tract contents and the body had not been attained after 20 to 24 hr., but seemed to be complete after 40 hr. The mean total exchangeable K was $50{\cdot}7 \pm 4{\cdot}0$ m. equiv. per kg. bodyweight, and $7{\cdot}2 \pm 2{\cdot}2$ per cent. of this was found in the contents of the digestive tract.

In the same 13 human subjects described above, 1·0 per cent. of the predicted total exchangeable K was in the contents of the digestive tract, or one-third of the total extracellular K.

Prudden, J. F., Danzig, L. E. and Stirman, J. A. **The effect of acute potassium depletion on the functional compartmentalization of water.** *Surg. Gynecol. Obstet.*, 1956, **102**, 553–564. [Surg. Res. Unit, Brooke Army Med. Centre, Fort Sam Houston, Tex.]

Acute depletion of exchangeable K was brought about in dogs by dialysis in the Kolff Brigham artificial kidney against a K-free bath. The bath used in the control group was similar, except that K was added in physiological quantity. The controls showed a tendency towards depletion of the extracellular compartment with good preservation of intracellular water volume. The K-depleted dogs lost considerably more of their total body water; interstitial fluid and intracellular water were lost; plasma volume tended to increase. Exchange of intracellular K for Na resulted in greater acceleration of the rates of water equilibration than could be accounted for through diminution in total body water.

The results are discussed in relation to the etiology of "chronic shock" in man.

LIKINS, R. C., MCCLURE, F. J. and STEERE, A. C. **Urinary excretion of fluoride following defluoridation of a water supply.** *Pub. Health Rep., Washington,* 1956, **71,** 217–220. [Lab. Oral Biol. Chem., Nat. Inst. Dent. Res., Pub. Health. Serv.]

Since March 1952 treatment of the communal water supply at Bartlett, Texas has reduced the F content from 8 to about 1 p.p.m. From the population, 116 boys and men who had used the water for from 2 to 50 years before its defluoridation were chosen. They were arranged in age groups by years from 7 to 16 and by decades from 20 to over 70 years. Fluorine was estimated in pooled samples of urine from the groups and the contents are tabulated for 0, 1, 5, 9, 20, 39, 47 and 113 weeks after defluoridation began.

Throughout the period the concentration of F in urine continued higher than in drinking water; the mean amounts for the children and adults were, in p.p.m., 6·5 and 7·7 initially and 2·2 and 2·5 at 113 weeks (*cf.* Abst. 585, Vol. 15). There was some evidence that in the first 20 weeks the rate of decrease in concentration was slower for children than for adults. It is suggested that in adults the change may have been in the surface-bound and more readily exchangeable F and, in the children, in the cycle of resorption and deposition associated with growth of bone.—D. Harvey.

4746

HERMAN, J. R. **Fluorine in urinary tract calculi.** *Proc. Soc. Exp. Biol. Med.,* 1956, **91,** 189–191. [Bronx Hosp., New York 56.]

Calculi from 10 patients were analysed for Ca, F, NH_4, Mg, oxalate, phosphate, urate and carbonate. In 8 of the 10 samples F was found; the amounts were parallel to those of Ca. Highest values were for a patient with a history of urolithiasis recurring for 17 years; one laboratory found 1790, the other 1560 p.p.m. F. In general, amounts of F were greatly in excess of those reported in the literature for human tissues.

4747

LEONE, N. C., GEEVER, E. F. and MORAN, N. C. (with BUTLER, W. M. (Jr.), WATTS, J. S. and GEISER, P. B.) **Acute and subacute toxicity studies of sodium fluoride in animals.** *Pub. Health Rep., Washington,* 1956, **71,** 459–467. [Dept. Med. Invest., Nat. Insts. Health, Pub. Health Serv.]

The toxicity of NaF was measured when it was given to 20 dogs in the following ways and to numbers of animals indicated: to 5 by continuous infusion until death occurred; to 9 also by infusion but in fractions of the acute lethal dose; to 2 by intravenous injection daily; to 4 in single doses by mouth; there were 7 untreated dogs as controls. The effects were studied also in mice given fluoride by mouth or intravenously.

With the first method 5·4 mg. F was injected per min. and for 4 dogs the mean acute lethal dose was 36·0 ± 0·5 mg. per kg. bodyweight. The fifth animal was given F in lower concentration, 1·1 mg. per min., and was excluded from consideration. With amounts above 15 mg. per kg. pulse pressure fell and when they reached between 20 and 30 mg. per kg. systolic and diastolic blood pressure also fell, at first slowly and then rapidly. For the second group infusion at the same rate, 5·4 mg. per min., was stopped when the amounts had reached 15, 20 or 25 mg. per kg.; the LD_{50} dose causing death within 36 hr. was concluded to be 20 mg. per kg. The dogs in the third group got 5 mg. F per kg. daily by vein for 23 days and remained in good health. In the fourth group single doses by mouth of 38, 81, 260 and 3100 mg. per kg. caused vomiting, but in from 18 to 24 hr. recovery was complete. In 11 of the dogs, 3, 7 and 1 in groups 1, 2 and 4, respectively, Ca was estimated in blood; it fell slightly in 9 of them. The LD_{50} doses for mice were, by mouth, 46·0 ± 1·6 mg. and intravenously 23·0 ± 0·9 mg. F per kg. The obvious pathological changes seen in all animals dying within 36 hr. were generalised hyperaemia and acute focal haemorrhages; there was no histological evidence of change in brain, heart, liver, kidney, lung, digestive tract or bone marrow.

It is concluded that relatively large amounts of F are required to produce acute toxic changes and that, since cumulative effects did not appear in dogs given intravenous doses daily for 3 weeks, small amounts may be given by that route to human subjects for study of F metabolism in man.

4748

MÜHLEMANN, H. R. and SCHNEIDER, R. Die mitotische Aktivät des Schilddrüsenepithels der Ratte bei Verabreichung von fluoridiertem Trinkwasser. [**Mitotic activity of the thyroid epithelium in the rat given fluoride in the drinking water.**] *Schweiz. med. Wochenschr.,* 1956, **86,** 625–627. [Histol. Abt., Zahnärztl. Inst., Univ. Zürich.] English summary.

Male white rats were kept under standardised conditions of light, heat and diet; no colchicine was given. Thirty-six of them were killed by decapitation after 3 weeks, half in the morning and half in the late evening. After 10 days 5 groups

of 8 rats for 7 days before decapitation were given NaF in the drinking water to yield concentrations of F of 0·5, 1·0, 2·0, 4·0 and 80 mg. per litre. The rats were fed on biscuits containing 0·2 mg. I per cent. All the rats given supplements were killed in the morning. In the rats not given supplements the mean number of mitotic figures in the thyroid epithelium was significantly greater in the rats killed in the morning than in those killed at night. There was no significant difference in the number of mitotic figures between the thyroids of rats given no supplement and killed in the morning and of rats given F, and there was no correlation between the number of mitotic figures and the concentration of F in the water.—L. Wills.

ZIPKIN, I. and SCOW, R. O. **Fluoride deposition in different segments of the tibia of the young growing rat.** *Amer. J. Physiol.*, 1956, **185,** 81–84. [Nat. Inst. Dent. Res., Nat. Insts. Health, Bethesda, Md.]

Two groups, each of twelve 20-day-old rats, were anaesthetised and a stainless steel pin was inserted into the middle third of the left tibia. One group was given 21 intraperitoneal injections of 0·5 ml. of a solution of NaF containing 300 p.p.m. F.; each rat was injected on weekdays only for 31 days. Distilled water and a stock diet containing 1 p.p.m. F were available to all rats to appetite. The gain in length at each end of the tibial diaphysis was estimated at intervals throughout the experiment. After 31 days the rats were killed and the tibiae were removed and divided into 4 segments, of which 3 contained portions of the diaphysis. The oven-dry, fat-free weight, ash and F content of the segments were estimated.

The intraperitoneal injections of NaF had no noticeable effect on the longitudinal growth rate or mass of the tibial segments. The ash content of the diaphyseal segments also was unaffected. The percentage of F in the proximal diaphyseal segment was similar to that in the middle diaphyseal segment, but 35 per cent. less than that in the proximal epiphysis.—G. F. Garton.

SANDERS, A. P., ISLEY, J. K., SHARPE, K., BAYLIN, G. J., SHINGLETON, W. W., HYMANS, J. C., RUFFIN, J. M. and REEVES, R. J. **Radioiodine recovery in feces following an I^{131} labeled fat test meal.** *Amer. J. Roentgenol.*, 1956, **75,** 386–389. [Dept. Radiol., Sch. Med., Duke Univ., Durham, N.C.]

The subjects were 24 adults free of digestive disorder and 25 patients with known gastrointestinal abnormalities such as chronic pancreatitis, cancer of the pancreas with and without obstruction, ileitis, sprue, Whipple's disease, cystic fibrosis, and vagotomy and gastric resection. Lugol's solution, 20 drops given with the test meal, effectively blocked the accumulation of radio-active iodine by the thyroid. A fat test meal labelled with ^{131}I and containing barium was given to each subject. All stools passed during the next 48 hr. were collected and ^{131}I was estimated as a percentage of the ingested dose of 25 μC.

The average total recovery in normal subjects was 0·6 per cent., with a standard deviation of 0·4 and a range of 0 to 1·4 per cent. In the test group the values were strikingly higher and similar to recoveries of faecal fat estimated in fat balance studies. One patient with sprue had 66·5 per cent. of the dose in the faeces and another with regional ileitis had 33·4 per cent.

It is suggested that the technique may serve as a new clinical laboratory test for steatorrhoea.

ROCHE, M., DE VENANZI, F., SPINETTI-BERTI, M., GERARDI, A., MENDEZ-MARTINEZ, J., and FORERO, J. **Iodine metabolism in a region of endemic goiter.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 661–664. [Inst. Invest. Med., Fund. Luis Roche, Plaza Morelos, Caracas.]

The 21 subjects lived in regions of endemic goitre in the Venezuelan Andes at an altitude above 4000 ft.

They were given 50 μC. of ^{131}I in 10 ml. saline injected intravenously. The thyroid radio-activity was counted 3 and 30 min. later. Blood was obtained after 5, 10 and 30 min. and urine after 35 min. Thyroid clearance was calculated. Renal clearance was calculated by dividing the average plasma content by the urine concentration. Conversion ratio was established by counting the

radio-activity in 3 ml. plasma. Saliva was obtained without stimulation and the ^{131}I was estimated. In urine, I was estimated chemically.

The 24-hr. thyroid ^{131}I uptake was slightly high and thyroid clearance rate was very high, which meant that there was increased avidity for I in the thyroid. The conversion ratios and the 24-hr. protein-bound ^{131}I were high. I in urine was somewhat low, but clearance was normal, showing that in these regions people do not conserve I through renal mechanisms. Salivary radio-activity was low.

It is suggested that as the subjects had thyroids which were barely palpable, or palpable but not readily visible, the increased extraction of I by the thyroids and the faster rate of I turnover compensated to a certain extent for the deficiency in the food and water.—B. W. Simpson.

4754

SLOVITER, H. A. and MOREL, F. **Localization of radioactive organic and inorganic iodine compounds in the posterior hypophysis of the rabbit.** *Arch. Biochem. Biophys.*, 1956, **62,** 217–221. [Dept. Biochem., Univ. Pennsylvania, Philadelphia.]

Male rabbits weighing about 2 kg. were fed on a low-iodine diet of oats and distilled water for 2 weeks or longer before subcutaneous injection of 0·5 mC. carrier-free $Na^{131}I$ per kg. bodyweight. After 48 hr. blood was drawn from the ear vein. The rabbit was then killed; the pituitary was removed, divided into anterior and posterior parts and weighed. The radio-activity of organic and inorganic fractions was measured in the anterior and posterior pituitaries and in plasma of 7 rabbits.

There was a greater concentration of radio-active inorganic and organic iodine compounds in the posterior pituitary than in the plasma. It is suggested that the inorganic I compounds found in the posterior pituitary may split off from the organic compounds found there.—B. W. Simpson.

IRON AND COPPER

4755

STURGEON, P. **Studies of iron requirements in infants and children. 2. The influence on normal infants of oral iron in therapeutic doses.** *Pediatrics*, 1956, **17,** 341–348. [Child Hosp., Sch. Med., Univ. S. California, Los Angeles.] Spanish and Interlingua summaries.

For part 1 see Abst 3208, Vol. 24.

2. Ferrous sulphate providing 90 mg. elemental iron in 3 doses daily for 6 weeks was prescribed for 40 infants. Of these 11 were eliminated either because they did not return for examination or because, on the evidence of the mothers, they had not taken at least half of the prescribed amount of Fe. Six were considered separately because the original Hb levels were below 9 g. per 100 ml. In the remaining 23 infants the mean Hb level was significantly higher at the end of the 6 weeks than initially. Red cell count, mean cell volume, mean cell Hb concentration, serum Cu, free erythrocyte protoporphyrin, serum Fe and total Fe-binding capacity were not significantly altered. In the 6 anaemic infants the response to Fe followed the usual pattern seen in anaemic adults.

F. C. Aitken.

4756

KALDOR, I. **Studies on intermediary iron metabolism. 7. The effect of splenectomy on the absorption and storage of iron in experimental anaemia. 8. The fate in mice of injected saccharated oxide of iron.** *Austral. J. Exp. Biol. Med. Sci.*, 1955, **33,** 637–643; 645–649. [N.S.W. Red Cross Blood Transfusion Serv.]

For part 6 see Abst. 5365, Vol. 25.

7. Groups of 10 intact rats and of 11 with spleens removed were given no treatment, or were made anaemic by repeated injections of phenylhydrazine for 4 months, or were similarly injected with phenylhydrazine and given a solution of ferrous ammonium sulphate as drinking fluid.

All the rats were injected every 3 weeks with neoarsphenamine against *Bartonella muris* and all were killed a month after the end of treatment with phenylhydrazine.

In operated rats the liver stored as much excess Fe as was stored by the spleen in intact rats. It was therefore concluded that the spleen has no part in the increased absorption of Fe during anaemia produced by phenylhydrazine.

8. There were 3 groups of mice initially about 60 days old and weighing 20 g. Sixteen mice received in 5 days 3 doses of 0·2, 0·2 and 0·4 mg. Fe as Ferrivenin by injection into the tail vein, 20 mice had the same doses intraperitoneally and 16 had no injection. Injected mice were killed 1, 2, 4 and 10 weeks after the last injection, controls were killed before and 11 weeks after the others were injected. Tissues were analysed for Fe.

Hb values declined by about 2 g. per 100 ml. in all 3 groups during the experiment. Liver Fe content doubled and spleen Fe rose slightly in untreated mice. In mice given Fe by vein the liver and spleen after 1 week contained 9 to 10 times as much Fe as in controls, and after 10 weeks liver Fe was still 4 times and spleen Fe 7 times that in controls. In mice given Fe intraperitoneally, liver Fe was doubled after a week and continued to rise slowly throughout the experiment, and the spleen gained an even smaller proportion of Fe. Microscopic deposits of precipitated Ferrivenin remained on the peritoneal membranes of mice in this group even after 10 weeks.

SCHWIETZER, C. Die Beeinflussung der Eisenresorption durch Polyphosphate. [**Effect of polyphosphates on absorption of iron.**] *Biochem. Ztschr.*, 1956, **328,** 35–38. [Abt. Physiol., Max von Pettenkofer Inst., Berlin-Dahlem.]

Fully grown dogs differing in weight and breed were given a titbit of raw meat mixed with finely powdered ferrous ammonium sulphate to give from 1 to 2·5 mg. Fe per kg. bodyweight and 2 g. polyphosphate (sodium tripolyphosphate, $Na_5P_3O_{10}$, sodium tetrapolyphosphate, $Na_6P_4O_{13}$, Graham salt, $(NaPO_3)_n . H_2O$ or Kurrol Salt, $(KPO_3)_n . H_2O$). In each of 8 tests 2 dogs had this mixture and 2 littermate controls had the meat and Fe without polyphosphate. Serum Fe was estimated in venous blood taken before and 2 hr. after feeding.

The results showed that tripolyphosphate was without effect, 2 g. tetrapolyphosphate would bind about 17 mg. Fe and 2 g. Graham salt or Kurrol salt about 30 mg. Possible reasons for the failure of the long-chain polyphosphates to bind more Fe are suggested.—W. M. Deans.

4758

PINNIGER, J. L. and HUTT, M. S. R. **The distribution and fate of iron injected intravenously into rabbits.** *J. Pathol. Bacteriol.*, 1956, **71,** 125–134. [Louis Jenner Lab., St. Thomas's Hosp., London.]

After intravenous injection of saccharated iron oxide into rabbits the iron was stored initially by the reticulo-endothelial system, mainly in the spleen, liver and bone marrow. After a short interval Fe appeared in the parenchymatous cells of the liver. When an iron-dextran compound was injected Fe appeared almost immediately in liver cells. A total of 1 g. saccharated Fe was given in several doses twice weekly without ill effect. This is equivalent in a patient to 30 g. Fe, which would require 300 injections of the usual dose of saccharated iron oxide or 120 injections of the iron-dextran compound into a subject who already had normal Fe stores. In rabbits higher doses caused kidney damage but no fibrosis of the liver.

It is suggested that repeated doses of the iron-dextran compound over a period of years might be used to initiate experimental haemochromatosis, since the Fe appears immediately in the liver parenchyma.—F. C. Aitken.

4759

KIESER, C. Der Einfluss von Normalkost und Aderlässen auf die diätetische Hämosiderose weisser Ratten. [**Effect of normal diet and bleeding on haemosiderosis of dietary origin in albino rats.**] *Ztschr. ges. exp. Med.*, 1956, **127,** 103–112. [Pathol. Inst., Univ. Zürich.]

There were 4 groups each of 10 rats weighing from 120 to 200 g. The control group received a normal diet. The experimental diet of cooked maize grits with 2 per cent. ferric citrate was given for 26 weeks to the other 3 groups. After this one group and half the controls were killed. The other 2 groups received normal diet for the next 26 weeks, and rats of 1 group and the remaining controls were bled, from 0·5 to 2·5 ml. blood being taken every 2 weeks. At the end all were killed.

The experimental diet was badly accepted. The rats became thin and listless, with rough coats. The incisors became loose and in some rats fell out, so that the rats starved to death soon after. Because of this the stock biscuits had to be soaked in the second part of the experiment. Eleven rats died in the first 26 weeks and the survivors weighed on the average only 60 g. They improved when the stock diet was restored.

The rats killed after 26 weeks on the maize and Fe diet had almost no visible body fat. The liver and spleen were structurally normal except for heavy deposits of haemosiderin which gave them a chocolate brown colour macroscopically and a dark blue colour in sections stained with Turnbull's blue. The portal lymph nodes, kidneys, adrenal, and duodenal wall also contained haemosiderin. In the rats killed after 6 months on experimental and 6 months on normal diet there was little haemosiderin in the liver except for clumps in histiocytes, and the parenchymal cells stained pale blue with Turnbull's blue. The spleen contained about a third as much haemosiderin as in rats killed immediately after having the experimental diet, and other tissues had little haemosiderin. In the rats similarly fed, but bled, only traces of haemosiderin remained in scattered deposits.

Thus haemosiderosis produced by diet does not damage the tissues, and the haemosiderin can readily be removed from the tissues and used for formation of Hb when this is necessary.

D. Duncan.

VIVANTE, A. **Reduction of normal and excessive liver iron by the administration of αα′-dipyridyl and other agents in the rat.** *Arch. internat. Pharmacodyn.*, 1956, **105,** 241–251. [Inst. Pharmacol., Univ. Rome.]

In 2 experiments the basal diet for rats was a mixture of barley meal 60, whole wheat flour 30, fishmeal 5, fresh brewer's yeast 5 and cod liver oil 2 parts. In the first it was given to 4 groups of 10 animals, alone or with a 1 : 1 mixture of gallic and tannic acids at the rate of 2 per cent., with a

1 : 4 mixture of $CaHPO_4$ and Na_2HPO_4, also at 2 per cent., or with 0·05 per cent. $\alpha\alpha'$-dipyridyl. At the beginning the rats weighed, on the average, 100 g. ; weight changes and Fe in liver were estimated after 5 weeks. The means for Fe in liver, in μg. per 100 mg. dry matter and for the groups in the above order were 74, 70, 77 and 59. In the second experiment there were 4 rats of average weight 90 g. in each of 4 groups and the additions were, respectively, 2 per cent. gallic or tannic acid, 2 per cent. phosphate mixture and 0·05 per cent. dipyridyl. Weight changes and Hb (Sahli) were measured over the same length of time. Differences in Hb in this experiment and in the gains in weight in both experiments were slight.

In a third test a pellagra-producing diet, 80 parts maize grits and 20 parts lard, was given alone to a control group and with 2 per cent. ferrous sulphate alone or with 0·05 per cent. dipyridyl to 2 experimental groups [the second group is said on p. 245 to have had dipyridyl alone]. After 5 weeks the means for Fe content of livers of 10 rats in each group were, in that order, 95, 181 and 136 μg. per 100 mg. dry matter.

Of the substances tested $\alpha\alpha'$-dipyridyl forms the most stable compound with ferrous iron and is the most effective in preventing deposition of Fe in the liver of rats. The possibility of its being used in treatment of haemochromatosis in man is suggested.—D. Harvey.

BUTLER, E. J. and NEWMAN, G. E. **The urinary excretion of copper and its concentration in the blood of normal human adults.** *J. Clin. Pathol.*, 1956, **9,** 157–161. [Dept. Biochem., Radcliffe Infirmary, Oxford.]

The copper content of human urine and blood was studied by an absorptiometric procedure involving selective extraction of Cu from acid digests by dithizone.

The output of Cu in urine in 12 healthy adults ranged from 3·9 to 29·6 μg. in 24 hr., mean 18·0. The Cu concentration of the urine ranged from 2·9 to 29·9 μg. Cu per litre, mean 15·4. Blood Cu of these subjects ranged from 66·2 to 84·9 μg. per 100 ml., mean 76·6. Diurnal variations in the urinary Cu output of 3 subjects were studied ; in each, Cu excretion was highest between midday and 4 p.m.

The values obtained for Cu excretion and blood Cu in the human adult by other workers are higher and more variable than those reported above. This may be due to failure to exclude contamination with Cu during sampling and analysis.

C. F. Mills.

4762

MILLS, C. F. **The dietary availability of copper in the form of naturally occurring organic complexes.** *Biochem. J.*, 1956, **63,** 190–193. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

With rats deficient in Cu the stable complexes of Cu obtained by passing an aqueous extract of herbage through a cation-exchange resin produced a greater physiological response (see Abst. 2097, Vol. 26) than equivalent amounts of Cu ions. The greater storage of Cu in the rat liver was confirmed with ^{64}Cu. It is suggested that Cu may pass through the intestinal mucosa in the form of such complexes.

See Absts. 298, Vol. 25 ; 4298, 4299, Vol. 26.

GALLAGHER, C. H., JUDAH, J. D. and REES, K. R. **The biochemistry of copper deficiency. 1. Enzymological disturbances, blood chemistry and excretion of amino-acids. 2. Synthetic processes.** *Proc. Roy. Soc.* [*B*], 1956, **145,** 134–150 ; 195–205. [Dept. Morbid Anat., University Coll. Hosp. Med. Sch., London.]

1. Young rats were reared without access to the mother's food and were given only mother's milk and later cow's milk treated with H_2S. At 23 days of age they were caged individually in glass and Perspex cages, kept free of contact with all metal, and fed on liquid whole milk treated with H_2S and supplemented with Fe, Mn, vitamins of the B group, E and A. Control rats received the same diet with a supplement of 50 μg. Cu daily ; one group was restricted in intake so that they lost weight as did rats severely depleted of Cu. Enzyme activity in the tissues was usually studied when the rats had been depleted for 10 to 13 weeks and had liver Cu contents of 2 to 4 μg. per g. dry weight and Hb concentrations of 5 to 6 g. per 100 ml. blood. Corresponding values for control rats were 14 to 17 μg. and 9 to 10 g.

Liver slices from deprived rats were normal in respiration, oxidative phosphorylation, anaerobic glycolysis, catalase, diphosphopyridine nucleotide (DPN)-cytochrome *c* reductase and diaphorase, transmethylase, *iso*citric dehydrogenase, malic dehydrogenase and glutamic dehydrogenase, except that in extreme deficiency *iso*citric dehydrogenase was increased and DPN-cytochrome *c* reductase was decreased. Cytochrome oxidase in liver was severely impaired even after 4 weeks of depletion and later was almost absent. Impairment was delayed in kidney and brain. Liver biopsy experiments showed that cytochrome oxidase was quickly restored when Cu was given to deprived rats. Haem α, which is probably the prosthetic group of cytochrome oxidase, was severely depleted or absent. Haem α injected intraperitoneally for 24 days did not increase cytochrome oxidase in a rat with advanced Cu deficiency.

Succinoxidase activity in liver was reduced by about 40 per cent. in Cu deficiency, but succinic dehydrogenase was normal.

Mitochondria from deficient rats were particularly prone to lose their enzyme activity on storage (" ageing "), and possible reasons for this are discussed.

Serum protein, Mg, Ca, Na, K and inorganic phosphate and excretion of amino acids in urine of deprived rats were normal.

2. Incorporation of ^{32}P as inorganic phosphate into the phospholipins and phosphatides of liver mitochondria *in vitro* was greatly reduced when the livers were from Cu-deficient rats. After intraperitoneal injection of ^{32}P into 2 normal and 2 Cu-deficient rats the latter incorporated only one-third of the normal amount of ^{32}P into liver phospholipins and phosphatides, but in brain mitochondria there was no difference. As phosphorylation of glycerol was normal and rates of synthesis of long-chain fatty acids were identical in deficient and control rats, it was concluded that the defect of phospholipin synthesis in Cu-deficient rats is in the process of attachment of fatty acids to α-glycerophosphate.

Synthesis of ribonucleic acid *in vivo* was not less in 2 Cu-deficient than in 2 control rats. There appeared to be no general decrease in incorporation of glycine-^{14}C into protein, but some deficient rats incorporated less into plasma proteins. The haem-copper complex became labelled with glycine-^{14}C at the same rate in control and deficient rats, but the deficient rats had only 5·2 g. Hb per 100 ml. blood against 9·9 g. in controls, so synthesis of protohaem must have been halved. The anaemia is ascribed to failure of blood formation, not to excessive destruction.

Possible relation between the disturbances of synthesis of phospholipins and cytochrome oxidase activity and their relevance to demyelination of the central nervous system are discussed.

D. Duncan.

BUSH, J. A., JENSEN, W. N., ATHENS, J. W., ASHENBRUCKER, H., CARTWRIGHT, G. E. and WINTROBE, M. M. **Studies on copper metabolism. 19. The kinetics of iron metabolism and erythrocyte life-span in copper-deficient swine.** *J. Exp. Med.*, 1956, **103,** 701–712. [Dept. Med., Coll. Med., Univ. Utah, Salt Lake City.]

For parts 16–18 see Absts. 3381–83, Vol. 26.

19. The diet and management of the pigs were described earlier (Abst. 2024, Vol. 23). Three Cu-deficient pigs received ^{59}Fe as chloride and its metabolism was compared with that in 18 normal pigs (Abst. 3377, Vol. 26).

Half the injected ^{59}Fe disappeared from the plasma in 0·28 hr., compared with 1·19 hr. in normal pigs. Rate of turnover of plasma iron was 1·76 mg. per kg. bodyweight daily and only 71 per cent. of the injected dose was incorporated into red cells, though the rate of incorporation was 1·24 mg. per kg. bodyweight daily, against 1·01 mg. in normal pigs. Red cell turnover of Fe was 1·18 mg. per kg. daily, against 0·59 mg. in normal pigs. The mean life span of red cells was only 13 days, 63 days in normal pigs. Labelled red cells from Cu-deficient pigs had a half-life of 9 days in other Cu-deficient pigs, 13 days in normal pigs. The corresponding half-lives of cells from normal pigs were 16 and 17 days, and cells from Fe-deficient transfused into Fe-deficient pigs had a half-life of 18·8 days.

Red cells of normal pigs were able to take up ^{64}Cu as cupric acetate both *in vivo* and *in vitro*. It is suggested that Cu is an essential component of the red cell in pigs and that deficiency of Cu limits both the survival of the red cells and their production in bone marrow.—D. Duncan.

OTHER MINERALS

4765

BURNS, M. J. and SALMON, W. D. **Effect of dietary cobalt on growing chicks and rats.** *J. Agric. Food Chem.*, 1956, **4,** 257–259. [Dept. Animal Husb. Nutrit., Alabama Polytech. Inst., Auburn.]

The growth of day-old chicks was significantly increased when 6 to 12 mg. Co per kg. was added to a semi-synthetic diet containing 5 per cent. fat and all known vitamins except vitamin B_{12}. When the fat content of the diet was increased to 20 per cent., 12 mg. Co per kg. depressed growth and increased the incidence of perosis, and the effect was aggravated when vitamin B_{12} was added at 30 μg. per kg. to that diet.

When 12 mg. Co per kg. was added to a diet deficient in folic acid, choline and vitamin B_{12} there was no stimulation of growth in rats. When folic acid at 2 mg. per kg. was given with 12 mg. Co per kg. an increase in growth was obtained equivalent to about half that obtained from 30 μg. vitamin B_{12} per kg. Folic acid alone gave no stimulation during the 28 days of experiment. The choline, methionine and fat contents of the diet did not influence the utilisation of Co by the rat.—C. F. Mills.

4766

WILLIAMS, M. A. and VAN REEN, R. (with GILE, J.) **Molybdenum toxicity in the rat.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 638 – 641. [McCollum-Pratt Inst., Johns Hopkins Univ., Baltimore, Md.]

Rats were given a basal diet containing, per cent., casein 20, glucose 69, maize oil 6·6, salt mixture 4, choline chloride 0·1, maize oil containing vitamins A and D and α-tocopherol 0·3. Vitamin B_1, riboflavin, nicotinic acid, pyridoxine, Ca pantothenate, biotin, folic acid, menadione, vitamin B_{12} and 4·0 mg. Cu per 100 g. diet were added. In the first experiment 8 rats received 0·08 per cent. Mo added as sodium molybdate and 8 others were pair-fed with the basal diet for 6 weeks. This amount of Mo failed to produce severe poisoning, and in the second experiment levels of 0·08, 0·12 and 0·14 per cent. Mo were given.

In the second experiment growth was retarded more with each increase in the dose of Mo. Some rats had diarrhoea, but none died. Food intake was depressed within 2 days after Mo was introduced, especially at 0·12 and 0·14 per cent. The Mo did not affect the ability of rats to acetylate a dose of 2·5 mg. *p*-aminobenzoic acid or to excrete hippuric acid after injection of benzoic acid. When the rats were killed alkaline phosphatase activity in the liver was increased in rats given Mo, but the 2 larger doses depressed alkaline phosphatase activity in the kidney and intestine.—D. Duncan.

4767

HUNT, J. N. **The influence of dietary sulphur on the urinary output of acid in man.** *Clin. Sci.*, 1956, **15,** 119–134. [Dept. Physiol., Guy's Hosp. Med. Sch., London, S.E.1.]

The *p*H of urine from adult human subjects receiving diets with alkaline ash, a milk diet or a diet containing large quantities of lettuce, did not tend to rise, and the amount of acid, $H^+ + NH_4^+$, was about equal to the amount of sulphate in the urine. The *p*H of urine from one subject on a diet devoid of animal products except butter rose to 7·12 after 7 days. One of 2 subjects on a Vegan diet twice gave urine with a *p*H of more than 7. These three excreted small amounts of acid and sulphate in the urine. When 3 other subjects received supplements of S as methionine or fillet steak the output of acid and sulphate in the urine increased. One of those given methionine as a supplement to a diet low in P excreted a relatively small amount of titratable H^+. The amount of H^+ appeared to be determined by the availability of dietary P as a buffer in urine. The amount of Ca in the urine increased with the titratable H^+.

In 8 subjects the urinary sulphate assumed to be equivalent to the amount of S oxidised in the body and the sole source of acid contributed only 61 to 10·6 per cent. of the actual acidity. This difference in acidity was apparently not due to excretion of sulphate into the gut and was not entirely due to amino acids or organic acids.

BÉLANGER, L. F. **Autoradiographic visualisation of the entry and transit of S^{35} methionine and cystine in the soft and hard tissues of the growing rat.** *Anat. Rec.*, 1956, **124,** 555–579. [Dept. Histol., Sch. Med., Univ. Ottawa.]

Nine littermate rats 8 days old received 5 μC. DL-methionine-^{35}S per g. bodyweight by subcutaneous injection and were killed after 1, 2, 6, 24, 48 or 96 hr. Seven similar rats received DL-cystine-^{35}S and were killed after 2 and 6 hr., 1, 2, 6 and 28 days. Autoradiographs were made from sections of tissues.

Skin and hair showed considerable uptake of ^{35}S from both amino acids; so did the mucosa of the palate. Enamel took up methionine but not cystine. Other strongly active tissues were bone, the exocrine part of the pancreas, the glands of the stomach and intestine, and the adrenal cortex. Diffuse activity was present in the liver, the white pulp of the spleen and haemopoietic bone marrow. Changes in activity of different tissues with time between injection and death are described in detail. There are 22 photographs.—D. Duncan.

WASE, A. W. **Absorption and distribution of radio-tungstate in bone and soft tissues.** *Arch. Biochem. Biophys.*, 1956, **61,** 272–277. [Div. Biol. Chem., Hahnemann Med. Coll., Philadelphia, Pa.]

Radio-active tungsten as tungstate, injected intraperitoneally into mice, became widely distributed through the body and was excreted rapidly via the digestive tract. More was accumulated and retained by bone than by other tissues.

The pattern of loss of tungsten from bone suggested that it existed in at least 2 phases, one of which was removed from bone more rapidly than the other.—R. Hill.

ACID BASE EQUILIBRIUM

4771

BONTING, S. L. and JANSEN, B. C. P. **The effect of a prolonged intake of phosphoric acid and citric acid in rats.** *Voeding*, 1956, **17,** 137–148. [Netherlands Inst. Nutrit., Univ. Amsterdam.]

Diets containing 0·40 or 0·75 per cent. H_3PO_4 or 1·20 per cent. citric acid had no harmful effect on rats, as shown by growth, reproduction, blood analysis, gross and microscopic appearance of the organs and teeth, mineral and N metabolism and tissue composition in 2 successive generations. Rats receiving H_3PO_4 retained more P and excreted more P in the urine. The acid was neutralised by the excretion of ammonia by the kidneys, a phosphate shift resulting in an increased titratable acidity and a decreased *p*H of the urine and by the excretion of more acid calcium phosphate in the faeces. All extra citric acid was metabolised.—A. Hepburn.

4772

O'DELL, B. L., VANDEPOPULIERE, J. M., MORRIS, E. R. and HOGAN, A. G. **Effect of a high phosphorus diet on acid-base balance in guinea pigs.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 220–223. [Dept. Agric. Chem., Univ. Missouri, Columbia.]

Growth studies were made on guineapigs fed to appetite for 8 weeks. The basal diet consisted of acid-washed casein 30, sucrose 47, cellu flour 15, soya bean oil 4 and salts 4 per cent., with vitamins A, C, D, E, K and those of the B group; it contained about 0·4 per cent. P and 0·9 per cent. Ca. Additions were made to the diet at the expense of sucrose to give P contents of 0·9 and 1·7 per cent.; Mg was added as MgO, K and Na as acetates and Ca as $CaCO_3$. The diets were analysed for Ca, Mg, Na, K and P; the Cl and S contents were calculated. Blood samples were taken for estimation of plasma CO_2 capacity and P content; *p*H and ammonia were estimated in urine.

The high-P diets produced poor growth, metastatic calcification and death; effects on blood and urine included a fall in *p*H of urine, a decrease in plasma CO_2 capacity and an increase in blood inorganic P. The addition of cations gave a more alkaline urine; a combination of Na or K and Mg had the best effects. The high sensitivity of the guineapig to an acid diet is attributed to the fact that only a negligible amount of ammonia is produced by the kidneys.—G. F. Garton.

METABOLISM OF WATER

4773

BREBNER, D. F., KERSLAKE, D. M. and WADDELL, J. L. **The diffusion of water vapour through human skin.** *J. Physiol.*, 1956, **132,** 225–231. [R.A.F. Inst. Aviation Med., Farnborough, Hants.]

Two nude human subjects were supplied with oxygen through a closed circuit system mounted on the platform of a continuously recording balance. With the weight loss from the respiratory tract accurately estimated and weight loss from constantly sweating areas excluded by covering them with sheets of polyvinyl chloride it was shown that the rate of loss of water was a simple function of the gradient in vapour pressure from saturation at about skin temperature to ambient water vapour pressure.—A. Hepburn.

4774

SCHMIDT-NIELSEN, B., SCHMIDT-NIELSEN, K., HOUPT, T. R. and JARNUM, S. A. **Water balance of the camel.** *Amer. J. Physiol.*, 1956, **185,** 185–194. [Dept. Zool., Duke Univ., Durham, N.C.]

Studies were made on, in all, 26 camels and 1 donkey. Twelve camels from the slaughterhouse were used for estimations of body water and its distribution, assay of pituitary antidiuretic hormone and histology of kidneys, digestive tract and skin; 12 were allowed to graze and urine was collected at intervals and analysed; and 2 camels and the donkey were hand fed and subjected to more intensive experiment. The diet was chiefly of dates and hay, sometimes with added salt or protein as groundnuts [details are not given and salt is not mentioned in relation to water balance].

Both experimental camels and the donkey continued to eat when deprived of water until 20 to 25 per cent. of bodyweight had been lost, when appetite gradually declined. "Expenditure" of water, or water "used for maintenance" in excess of the water formed by oxidative metabolism, was at a much lower rate in the camel, 1 per cent. of bodyweight daily, than in the donkey, 2·5 per cent. of bodyweight daily. Hence, to reach the same degree of desiccation took 2·5 times as long in the camel as in the donkey. Expenditure rose with temperature and was

higher when water was freely available than when it was withdrawn. Camels used more water when shorn; the coat protected against heat. Urine flow varied with the diet, but in relation to bodyweight was about 3 times as great in the donkey as in the camel. Water in faeces per 100 g. dry matter was low. Water evaporated, estimated as expenditure less water in urine and faeces, increased with temperature and with water supply.

The camel expends water faster than it is formed by oxidation in the body, so it is never independent of a supply of water. When not working, in cool weather, it could theoretically go without water for 30 or 40 days. One was deprived of water for 17 days in the sun in summer without ill effect.—I. Leitch.

4775

ANDERSSON, B. and MCCANN, S. M. **The effect of hypothalamic lesions on the water intake of the dog.** *Acta physiol. scand.*, 1956, **35,** 312–320. [Dept. Physiol., Kgl. Veterinärhögsk., Stockholm.]

Lesions were made electrically in the hypothalamus of 15 dogs. Before operation all the dogs drank between 20 and 25 ml. water per kg. bodyweight daily. After operation the water intake was significantly reduced in 6, and 3 of these drank no water for 9 to 14 days, despite normal food intake and progressive dehydration. They readily drank milk or broth. Four of the 6 dogs partly recovered their appetite for water later. The electrolyte balances were not greatly affected, except in 1 dog which retained Na and Cl for 3 weeks. Diabetes insipidus occurred in 2 dogs, but was not related to absence of drinking. Four of the 15 dogs, predominantly those with the largest lesions, died soon after operation. In the dogs which survived and showed absence of drinking, the "drinking area" of the hypothalamus seemed to be similar to that in the goat (Abst. 3887, Vol. 25).—D. Duncan.

ROGERS, L. L., PELTON, R. B. and WILLIAMS, R. J. **Voluntary alcohol consumption by rats following administration of glutamine.** *J. Biol. Chem.*, 1955, **214,** 503–506. [Biochem. Inst., Univ. Texas, Austin.]

4779

NICHOLS, C. W. (Jr.), SIPERSTEIN, M. D., GAFFEY, W., LINDSAY, S. and CHAIKOFF, I. L. **Does the ingestion of alcohol influence the development of arteriosclerosis in fowls?** *J. Exp. Med.*, 1956, **103,** 465–475. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

Experiments with 224 cockerels lasted 12 months. Some birds were supplied with 15 per cent. ethanol solution or wine containing 12 per cent. ethanol for drinking and others were supplied with the same energy intake from extra food.

Critical statistical analysis showed that arteriosclerosis, naturally occurring or produced by injections of stilboestrol, and lipid infiltration of blood vessels were not affected by alcohol.

A. Hepburn.

4780

FREEMAN, S., KANABROCKI, E. L. and INMAN, C. W. **The influence of diet and of exogenous glucuronolactone or glucuronate upon the urinary and serum glucuronic acid of adult human subjects.** *J. Lab. Clin. Med.*, 1956, **47,** 583–591. [Dept. Biochem., Northwestern Univ. Med. Sch., Chicago, Ill.]

In 9 normal subjects studied for 5 consecutive days average excretion of glucuronic acid was 449 ± 43 mg. in 24 hr. In 4 of 5 subjects there was evidence of diurnal variation, the rate being lowest between 10 p.m. and 7 a.m. The amount in urine was unaffected by intake of protein; on the average it was 439 mg. with 0·7 g. protein per kg. bodyweight and 462 mg. with 1·7 g. When glucuronolactone, 0·1 g. per kg., was ingested the percentage of glucuronic acid excreted was 12·7 in normal men, and in 2 patients, one with stone in the kidney and the other with osteoporosis, the percentages were 9·9 and 7·1. When a healthy subject took up to 10 times that amount there was little change in excretion, maximum 17·6 per cent.

In some tests the derivatives were given by vein. With glucuronolactone, 0·1 g. per kg. bodyweight, the concentration of glucuronic acid in serum rose,

about half appeared in the urine, but in 7 hr. the concentration in urine was back to normal. When calcium glucuronate was injected the amount excreted in the urine was greater, 87 per cent.

The results are discussed.—D. Harvey.

4781

ROVATI, A. L. Influenza di diete diverse sull' escrezione di acido glucuronico. [**Influence of different diets on the excretion of glucuronic acid.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31**, 974–976. [Ist. Farmacol., Univ. Pavia.]

Urine was collected from 20 rats weighing about 215 g., fed successively on a stock diet and on dried milk. The content of total N in the 2 diets was about the same. Analysis of 138 samples of urine showed that the content of total and of conjugated glucuronic acid was significantly greater when the diet was milk powder. After injection of glucuronic acid lactone or glucose or ascorbic acid or pyruvate, there was an increase in the amount of total or conjugated glucuronic acid in the urine only with the stock diet and glucuronic acid lactone.—E. M. Hume.

4782

PATTERSON, E. L., BROQUIST, H. P., SALTZA, M. H. v., ALBRECHT, A., STOKSTAD, E. L. R. and JUKES, T. H. **Observations on the urinary excretion of thioctic acid.** *Amer. J. Clin. Nutrition*, 1956, **4**, 269–274. [Sect. Nutrit. Physiol., Res. Div., American Cyanamid Company, Lederle Labs., Pearl River, N.Y.]

Thioctic acid (6 : 8-dithiooctanoic acid) and thioctic acid monoxide are equally active for *Corynebacterium bovis* and *Streptococcus faecalis*. The activity of fresh human urine when estimated with *C. bovis* was 10 to 180 times as much as with *S. faecalis*, but with urine stored several days at 4° C. both organisms gave values similar to those obtained with *C. bovis* and fresh urine. In fresh urine thioctic acid activity is in an unidentified form, which changes during storage to thioctic acid. The unidentified form of thioctic acid was found in the urine of several species. When DL-thioctic acid (also known as DL-lipoic acid) was administered to rabbits, rats and human subjects the percentage recovered in the urine was 0·6 to 10, all in the form of the unidentified conjugate. Examination of the organs of rabbits showed no evidence of storage of injected DL-thioctic acid.

Vitamin B_1 given with the DL-thioctic acid did not influence the rate of excretion or the amount of thioctic acid excreted by men.—F. C. Aitken.

4783

WICK, A. N. and JOSEPH, L. **The fate of ingested polyoxyethylene (20) sorbitan monostearate in rats.** *Food Res.*, 1956, **21**, 250–253. [Scripps Metabol. Clin., La Jolla, Calif.]

For previous work see Abst. 3295, Title 4767, Vol. 23.

After rats were given by stomach tube polyoxyethylene (20) sorbitan monostearate (Tween 60) labelled with ^{14}C in the polyol moiety, 6 to 10 per cent. of the ^{14}C was recovered in the urine, 2 to 7 per cent. in the expired CO_2 and 67 to 93 per cent. in the faeces. Total recovery ranged from 82 to 102 per cent. Only negligible amounts were found in lymph.—A. Hepburn.

4784

BORNMANN, G., LOESER, A., MIKULICZ, K. and RITTER, K. Über das Verhalten des Organismus bei Einwirkung verschiedener Weichmacher. [**Reaction of the organism to the effect of several plasticisers.**] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1956, **103**, 413–424. [Pharmakol. Inst., Univ. Münster.]

A full account is given of acute, subacute (6-week) and chronic (1-year) experiments, including a reproduction test, mainly with rats, about 1400 in all, but a few with rabbits and dogs, on the toxicity of 5 plasticisers, namely, benzyloctyladipate, dibutylphthalate, Mesamoll, di*cyclo*hexylphthalate and PW 63/51, used in the manufacture of plastic wrappings for foods. The substances were given dissolved or suspended in olive oil, by stomach tube.

The toxicity of all was very slight, that of Mesamoll and PW 63/51 least. Since 3 of the rats given dibutylphthalate in the 1-year experiment were found to have sarcoma, it is considered that further tests with this substance are essential.

METABOLISM OF CELLS, TISSUES, ETC.

GENERAL PHYSIOLOGY

4785

MOYSON, F. Limitations de l'emploi des coupes tissulaires pour l'étude des phénomenes métaboliques. [**Limitations in the use of tissue slices in the study of metabolic phenomena.**] *Experientia*, 1956, **12**, 103–104. [Lab. Animal Morphol., Univ. Libre, Brussels. English summary.

When cylinders of liver 1 mm. in diameter were incubated for 60 min. with glycine-1-^{14}C and then sectioned it was found that the basophilia

characteristic of ribonucleic acid had disappeared from all the cells except a layer 3 to 5 cells deep on the outside. Autoradiographs showed that only these outer cells had taken up the labelled glycine. Thus tissue slices give results valuable only qualitatively in metabolic studies.

LOCKER, A. and SPITZY, K. H. Die Atmung von Zellen und Geweben *in vitro* als physiologische Methode und als Modellvorgang. [**Respiration of cells and tissues *in vitro* as a physiological method and "model" process.**] *Ztschr. ges. exp. Med.*, 1956, **127,** 1–15. [1. Med. Klin., Univ. Vienna.]

In the study of tissue respiration homogenates have recently been used in preference to slices. It is doubtful whether results with homogenates should be taken as representing processes in intact, living tissues; since the cells are ruptured, the results may more nearly approximate maximum possible performance within the cell (*Ztschr. ges. exp. Med.*, 1951, **118,** 155). To investigate this further, liver slices from normally fed rats and rats fasted for 48 hr., and leucocytes from untreated patients with lymphatic or myeloid leucaemia were used, in Krebs bicarbonate Ringer medium with or without 200 mg. glucose per cent., or later, for the endogenous respiration of leucocytes, with 50 mg. glucose per cent. Oxygen consumption in each system showed a gradual fall which could be related to the failure of supply of energy in the cell, the supply of glucose in the medium, and, in the liver, the amount of injury to surface cells. Respiration with carbohydrate as basis continued in liver for about 20 hr., in leucocytes for 17 to 20 hr.; with fat as basis for 140 hr. in liver, 81 or 62 hr. in lymphatic and 35 hr. in myeloid cells. On account of the irreversible fall of respiration, and the changes, *e.g.* swelling, of the tissue cells, experiments with tissue slices are to be regarded as "model" experiments only; those with leucocytes are more nearly related to natural events.—I. Leitch.

DICK, D. A. T. **Growth and function of the foetal liver.** *J. Embryol. Exp. Morphol.*, 1956, **4,** 97–109. [Dept. Anat., Univ. Glasgow.]

Weight of liver declines relative to bodyweight in the mammalian foetus. To discover whether the change is due to the shift of blood formation from liver to bone marrow, or to a reduction of true hepatic tissue, 51 sheep foetuses from 28 to 530 mm. forehead-rump length were taken from ewes of "many different breeds". Livers were prepared and hepatic cell nuclei were counted by techniques described.

At 35 days, liver weight was 11 per cent. of bodyweight; at term (150 days) only 3 or 4 per cent. At these times hepatic cells per 100 g. bodyweight, called relative hepatic cell populations, were 16×10^8 and 6×10^8, showing that there is a decrease in true hepatic tissue as well as in haemopoietic tissue. When age-specific growth rates were computed they were found to be linearly related to relative hepatic cell populations. On the assumption that growth of liver is related to functional demands on it, the decline of hepatic cells relative to bodyweight may connote a decline of demand associated with decline of specific growth rate or an increase of functional capacity of the individual cell, possibilities which may be put to the test.—I. Leitch.

SMITH, R. E. **Quantitative relations between liver mitochondria metabolism and total body weight in mammals.** *Ann. N.Y. Acad. Sci.*, 1956, **62,** 403–421. [Dept. Physiol., Med. Sch., Univ. California, Los Angeles.]

Adult rats, rabbits, sheep and steers were starved for 15 to 18 hr. and then killed. The livers were chilled and exsanguinated by perfusion with 0·16 *M* KCl at 0° to 5° C. and homogenates were prepared in KCl solution. Respiration was studied in a Warburg apparatus with whole homogenate or the mitochondrial fractions prepared by centrifuging. Mitochondrial counts were made on the fraction with a bacterial counting chamber and phase contrast microscope.

The numbers of mitochondria per g. dry liver decreased progressively with increasing size of the species, though the decrease from sheep to steer was not significant. The apparent dry mass of the individual mitochondrion increased somewhat with increasing size of animal; the differences between successive species were not significant, but those between rat and sheep or between rat or rabbit and steer were significant. Utilisation of oxygen, expressed as Q_{O_2}, decreased with increasing body size, but utilisation of oxygen per mitochondrion did not vary significantly. It is therefore concluded that Q_{O_2} of the homogenate is more closely dependent on the number than on the size of the mitochondria. The mass of mitochondria bears the same quantitative relation to total metabolism as to total body size, and the relative amounts of mitochondria in a given tissue may prove to be decisive for the regression of utilisation of oxygen on total body size for the species.

O'CONNOR, R. J. **Observations on the nature of the relationship between cell division and carbohydrate metabolism.** *J. Embryol. Exp. Morphol.*, 1954, **2,** 26–37. [John Burford Carlill

Pathol. Labs., Westminster Sch. Med., Horseferry Rd., London, S.W.1.]

Metabolism was studied in liver tissue from chicken embryos at different stages of incubation from about 5·5 to 10 days. Total acid production and rate of utilisation of glucose were estimated by methods described, and mitotic activity was estimated histologically.

Before the stage when glycogen appeared, at about 6·9 days of incubation, the estimated rate of acid production from glucose, the rate of utilisation of glucose and the mitotic activity declined in much the same way. When glycogen appeared mitotic activity almost ceased to decline, but acid production and utilisation of glucose disappeared.

The implications of the findings are discussed.

GRAY, D. E. and DELUCA, H. A. **Use of desoxyribonucleic acid as a reference standard in metabolic experiments.** *Amer. J. Physiol.*, 1956, **184,** 301–303. [Dept. Biochem., Univ. W. Ontario, London.]

Formation of glycogen, uptake of glucose and consumption of oxygen by diaphragms taken from rats fed on a diet containing 5 per cent. protein were greater than in diaphragms from rats given 22 per cent. protein. When expressed as metabolism per cell, calculated from the content of deoxyribonucleic acid phosphorus, this difference disappeared. The mass of the diaphragm cell decreased on the low-protein diet even when both groups had an equal energy intake, and the number of cells in a given weight of tissue increased.

ARRIGO, L. Meccanismo di azione del fattore lipotropo pancreatico: comportamento del consumo di ossigeno del fegato steatosico di ratto. [**Mechanism of action of lipotropic substances from the pancreas: behaviour of oxygen consumption of fatty liver from the rat.**] *Quad Nutrizione*, 1954, **14,** 165–176. [Ist. Naz. Nutriz. C.N.R.] Summaries, French, p. 192, English p. 194, German p. 196.

Rats of both sexes, 4 to 5 months old, were fed on about 15 g. daily of a mixed diet slightly low in protein. Ten rats on this diet were considered as normal, 12 received a series of injections of CCl_4 and 30 received both CCl_4 and " protective " injections of pancreatic lipotropic factor (Arrigo and Montini, *Quad. Nutrizione*, 1954, **13,** No. 1/2). The rats were then killed and oxygen consumption of liver tissue was studied by the Warburg method.

The Q_{O_2} of fatty liver from rats treated with CCl_4 was not significantly above normal whether expressed on weight of tissue or N content. The Q_{O_2} of liver from rats treated with both CCl_4 and pancreatic lipotropic factor was significantly above normal, and almost identical values were obtained when the pancreatic extract was added to normal liver tissue. The liver tissue metabolised butyrate and caprylate, the latter more rapidly, except that liver from rats treated with CCl_4 alone metabolised caprylate poorly. Utilisation of both butyrate and caprylate was best in liver from rats given pancreatic extract and then in normal liver with added pancreatic extract.

The protective effect of pancreatic lipotropic substance on the liver was demonstrated chemically and histologically.—D. Duncan.

ARATA, D., SVENNEBY, G., WILLIAMS, J. N. (Jr.) and ELVEHJEM, C. A. **Metabolic factors and the development of fatty livers in partial threonine deficiency.** *J. Biol. Chem.*, 1956, **219,** 327–333. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Groups of weanling male rats had a basal diet deficient in threonine, with or without a supplement of threonine. They were killed at intervals up to 15 days and the oxygen uptake of liver homogenates was measured with or without the addition of diphosphopyridine nucleotide (DPN).

Endogenous oxidation in homogenates from rats given threonine increased immediately and rapidly after weaning, but in rats deprived of threonine there was a delay of up to 10 days, followed by a sharp rise. Addition of DPN gave a constant degree of stimulation of endogenous oxidation in homogenates from rats given threonine, and a significantly greater stimulation in those from threonine-deficient rats. Accumulation of fat in the livers occurred in rats on the basal diet alone, but not when threonine was supplied.

It is concluded that impaired production of DPN and defective metabolism of endogenous DPN in liver are largely responsible for accumulation of fat in the liver in threonine deficiency.

DUNCOMBE, W. G. and GLASCOCK, R. F. **Studies on the metabolism of mammary tissues *in vitro*. 1. Oxidation of acetate and glucose by slices of lactating rat mammary gland. 2. Oxidation of acetate and glucose by slices of lactating sheep mammary gland.** *Biochem. J.*, 1956, **63,** 326–332; 332–336. [Nat. Inst. Res. Dairying, Univ. Reading.]

1. Mammary tissue was obtained from rats between the thirteenth and fifteenth days of their first lactation.

When acetate was metabolised alone the carboxyl C atom was always oxidised more rapidly than the methyl atom, in ratios of between 1·27 and 1·54 to 1. When glucose was added the rate of oxidation of both C atoms was reduced, but the methyl atom was more affected, so that the ratio rose to between 1·72 and 2·93. When pyruvate replaced glucose the ratio rose similarly, but the total rate of oxidation of the acetate was not consistently affected. Diphosphopyridine nucleotide (DPN) did not significantly affect the oxidation of acetate when glucose was present. Nicotinamide increased the rate of oxidation of both C atoms, but not the ratio. The results agree with the hypothesis that the enzyme systems catabolising glucose and oxidising acetate compete for DPN. They are discussed in relation to the work of Strisower *et al.* (*J. Biol. Chem.*, 1952, **198,** 115).

When glucose and acetate were present together, the total C of glucose was oxidised 40 times as fast as that of acetate. The C_1 atom of glucose was oxidised about 10 times as fast as the methyl C of acetate. It is concluded that most of the C_1 atoms which appear as CO_2 are not oxidised along the glycolytic pathway. If they are oxidised directly, pyruvate would not be expected to reduce the rate of oxidation of C_1 atoms; the reason why it does so is being studied.

2. Mammary tissue was obtained from ewes after 20 to 27 days of their first lactation.

The rate of oxidation of the total C of glucose was depressed when pyruvate was added, but oxidation of the C_1 atom was not affected. Acetate considerably increased the rate of oxidation of both total C and C_1 atoms of glucose. When acetate was the basic substrate, addition of glucose increased the rate of oxidation of both carboxyl and methyl C atoms in the same ratio. Pyruvate depressed the oxidation of both C atoms of acetate, especially that of the methyl group, so that the ratio was increased.

The results are contrasted with those obtained with rat tissue. Acetate was oxidised several times as fast by sheep as by rat.—D. Duncan.

NAKADA, H. I. **The metabolism of fructose by isolated rat diaphragms.** *J. Biol. Chem.*, 1956, **219,** 319–326. [Scripps Metabol. Clin., La Jolla, Calif.]

Isolated rat diaphragms took up and oxidised fructose, more in the presence of insulin, less in the presence of glucose or glucosamine. Formation of glycogen from fructose was much reduced in the presence of glucose; fructose was thought in these circumstances to form fructose-1-phosphate.

The direct contribution of fructose to energy metabolism of muscle cells is insignificant.

D. Duncan.

4798

NAKADA, H. I. and WICK, A. N. **Galactose metabolism by the isolated rat diaphragm.** *Amer. J. Physiol.*, 1956, **185,** 23–26. [Scripps Clin., La Jolla, Calif.]

Insulin increased the uptake of galactose by rat diaphragm *in vitro*, but the increase was not closely related to the concentration of galactose in the medium. Galactose did not affect the oxidation or uptake of glucose, though glucose reduced the oxidation of galactose. Glucose caused much greater reduction in both oxidation and uptake of fructose, but galactose hardly affected metabolism of fructose.

In 2 hr. diaphragm tissue took up about two-thirds as much galactose as glucose. When the diaphragm tissue was divided into fractions, much of the radio-activity of the glucose was found in glycogen, CO_2, hexose phosphates and "protein", but the activity from galactose was almost all in

free sugar, and its distribution was not affected by the presence of KF, to inhibit phosphorylation.

The differences in behaviour of glucose and galactose are discussed.—D. Duncan.

OMACHI, A. and LIFSON, N. (with MICHEL, S. L. and SWANSON, J. A.) **Metabolism of isotopic lactate by the isolated perfused dog gastrocnemius.** *Amer. J. Physiol.*, 1956, **185,** 35–40. [Dept. Physiol., Univ. Minnesota, Minneapolis.]

Isolated gastrocnemius muscles of dogs were perfused with the animals' own blood, to which isotopic lactate was added in the course of experiments. CO_2 was collected from the closed circuit. Contraction of the muscle was produced by electrical stimulation of the sciatic nerve.

When resting muscles were given lactate labelled with ^{13}C in the carboxyl group, up to 12 and 13 per cent. of the respired CO_2 was derived from that lactate. When contracting muscles were given similar lactate the proportions were 27 and 29 per cent., and when contracting muscles were given lactate labelled in the α, β positions they were 25 and 27 per cent. Although the rate of production of CO_2 was several times as great in active as in resting muscle, the increase in utilisation of labelled lactate was even greater.

Evidence for conversion of lactate to glycogen was found in only 3 of 14 preparations studied; all 3 were resting muscles given α,β-labelled lactate with insulin and moderate amounts of glucose. All the detectable ^{13}C was in C atoms 1, 2, 5 and 6 of the hexose units of glycogen. No labelled glycogen was found in resting muscle given carboxyl-labelled lactate or in stimulated muscle.

NIKLAS, A. and OEHLERT, W. (with ROESCH, R.) Autoradiographische Untersuchung der Grösse des Eiweiss-stoffwechsels verschiedener Organe, Gewebe und Zellarten. [**Autoradiographic study of protein turnover in different organs, tissues and types of cell.**] *Beitr. pathol. Anat.*, 1956, **116,** 93–123. [Med. Klin., Univ. Cologne.]

The animals were healthy adults fed on normal diets until 12 hr. before experiment; there were 5 rats, 6 mice and 1 rabbit. Each received by stomach tube sulphur amino acids labelled with ^{35}S, produced by growing *Torula utilis* in media with labelled sulphate. The yeast itself was given, or else a hydrolysate, or ^{35}S-methionine was isolated and given alone. The doses were about 10 mC. for rats, 1 mC. for mice and 40 mC. for the rabbit. The animals were killed at different times after the dose was given and tissues were fixed. Sections were made and autoradiographs indicated the distribution of ^{35}S. The method of estimating it in relation to the whole body or tissue is explained.

The tissues are divided into 4 groups according to the intensity of accumulation of labelled methionine and cystine. The greatest accumulation was in cells secreting protein, the gastric chief cells, pancreatic glandular epithelium and serous salivary glands, and also in ganglion cells, the adrenal cortex, the chorioid plexus and the reticulo-endothelial cells. The second group included crypt cells of the intestine, the stratum germinativum of the skin, hair follicles, spermatogonia, follicle and lutein cells of the ovary, epiphyseal cartilage, and also the liver and renal cortex. The third group was surface epithelia. The fourth group, muscle, connective tissue and skeletal tissues, accumulated ^{35}S at about one-fiftieth of the rate of the first group. The order of grouping corresponds closely with the values in the literature for ribonucleic acid content of tissues, and confirms the concept of Caspersson ("Cell Growth and Cell Function", Norton, N.Y., 1950) that protein turnover is proportional to the ribonucleic acid content of the cell.—D. Duncan.

PRUDDEN, J. F., YOUNG, M. K. and STIRMAN, J. A. **Studies on growth hormone. 1. The effects of growth hormone and insulin upon the synthesis of protein in perfused livers.** *J. Lab. Clin. Med.*, 1956, **47,** 370–385. [Surg. Res. Unit, Brooke Army Med. Centre, Fort Sam Houston, Tex.]

1. Whole rabbit livers removed under surgically aseptic conditions were perfused with a mixture of equal parts of defibrinated rabbit blood and a solution containing electrolytes and 12 amino acids. The perfusate was isosmotic with rabbit plasma. The experiments are described in detail and results are tabulated and shown in graphs.

Addition of growth hormone to the perfusate considerably increased the synthesis of liver protein, and plasma protein was drawn upon for this. Insulin caused a high uptake of plasma

protein by the liver and increased production of urea, not so much of liver protein. It is concluded that the growth hormone produced a shift in equilibrium away from polypeptides and towards amino acids. Insulin increased glycogen formation and improved the maintenance of liver lipids.

The significance of the findings is discussed.

MARTINO SAVINO, F. Intervención del riñon estudiada con el fósforo radiactivo, en el metabolismo de las grasas y en la formación de las hormonas córticosuprarrenales. [**Participation of the kidney, studied with radioactive phosphorus, in fat metabolism and the formation of adrenocortical hormones.**] *Rev. clín. española*, 1956, **60,** 166–169. [Hosp. Central Cruz Roja, Madrid.] English, German and French summaries.

^{32}P was injected intravenously into 5 cats at 1 μC. per g. bodyweight as disodium phosphate. The animals were killed from 1 hr. to 15 days later and tissues were examined for radio-activity. In decreasing order of activity were the kidney, adrenal cortex, liver, spleen, pancreas and muscles, skin, brain and heart and pituitary.

Autoradiographs were made from kidneys and adrenals. The distribution of ^{32}P was mainly in the kidney cortex. The radio-activity was not removed by washing in running water for 12 hr. or by incubation with hyaluronidase, trypsin or papain, but disappeared when the kidney was treated with fat solvents. It is considered that P in the kidney is mostly in lipids. The high concentration in the adrenal cortex suggests the the strong relation between the two tissues and it is thought that the kidney may form steroid hormones or their precursors.

It is considered that the kidney plays an important part in intermediate metabolism of lipids and that its enormous oxygen consumption may be used in oxidising fats and in producing heat.

KLINE, D. L. and DELUCA, H. A. **Phospholipid metabolism in liver slices. Labelling of phospholipids with acetate-1-C^{14}.** *Canad. J. Biochem. Physiol.*, 1956, **34,** 429–440. [Dept. Biochem., Univ. W. Ontario, London.]

Liver slices were obtained from male rats and guineapigs which had been fed on a diet containing carbohydrate 53, protein 20, and fat 3·5 per cent. The slices were incubated with acetate-1-^{14}C at 37·5° C. for 4 hr. in Krebs Ringer bicarbonate buffer; lipids were then extracted, fractionated and assayed for ^{14}C.

The optimum *p*H for labelling of phospholipins and fatty acids of the acetone-soluble lipids was 6·8 to 7·4 and for cholesterol 6·6 to 6·8. No incorporation of acetate into lipids was found when nitrogen was employed as the gas phase. When glucose was added to the incubation medium the labelling of phospholipins and acetone-soluble lipids increased slightly. Incorporation of ^{14}C into all lipid fractions was less when cyanide, fluoride, iodoacetate or 2 : 4-dinitrophenol was added to the medium. Malonate inhibited the incorporation of ^{14}C-acetate into cholesterol, but did not affect the labelling of phospholipins. When acetate-1-^{14}C was replaced by glycine-2-^{14}C, glycerol-1-^{14}C or fructose-1-^{14}C, phospholipins were labelled; formate-^{14}C, lactate-1-^{14}C and glucose-^{14}C did not serve as precursors of phospholipins. No substrate, other than acetate, was incorporated into cholesterol to any significant extent.

G. A. Garton.

GASTEVA, S. V. Obmen fosfora fosfolipinov i nukleoproteidov mozga u predstavitelei raznykh klassov pozvonochnykh. [**Phosphorus exchange of brain phospholipins and nucleoproteins in representatives of different classes of vertebrates.**] *Dokl. Akad. Nauk SSSR*, 1956, **106**, 873–876. [Lab. Sravnitel'n. Biokhim., Inst. Fiziol. I.P. Pavlova, Akad. Nauk SSSR.]

The content of phospholipins, nucleic acids and phosphoproteins and rate of phosphorus exchange in the central nervous system were studied with radio-active phosphorus. Subcutaneous injections of ^{32}P in sodium phosphate solution, 0·5 mC. per kg. bodyweight, were given to carp, perch, frog, tortoise, hen, pigeon, white rat and dog. The animals were killed 12 hr. after the injection and forebrain, cerebellum, brain stem and spinal cord were studied.

The quantity of phospholipins and their distribution in the brain were similar in all animals. An increase of phospholipins in the caudal direction was found, from 1000 to 1500 μg. P per g. in the forebrain to 2500 to 3000 μg. per g. in the spinal cord. The quantity of phospholipins in tortoise and frog brain was slightly less than in other animals.

The ribonucleic acid (RNA) fraction was evenly distributed in the brain and was found in similar quantities in different species. In all animals cerebellum was found to have 3 to 4 times as much deoxyribonucleic acid (DNA) as other parts of the brain, which had about the same amount; the range of variation for all animals and all parts of the brain was from 15 to 40 μg. P per g. tissue.

In rate of phosphorus exchange the animals could be clearly differentiated into 2 groups, cold-blooded and warm-blooded. In cold-blooded animals the rate of exchange of phospholipins is 0·5 to 1·5 per cent. in 12 hr.; in warm-blooded it is 5 to 10 times as great. For cold-blooded animals minimum values were found in fish and maximum values in summer frog. Among warm-blooded animals minimum values were found in dog, maximum in birds. In birds and mammals the greatest rate of exchange of phospholipins was found in cerebellum. In all animals the rate of exchange in spinal cord was lower than in brain. The rate of exchange of RNA is also different in cold- and warm-blooded animals. There was no difference among warm-blooded animals, but among the cold-blooded values for frogs were 2 to 2·5 times greater than for fish and values for tortoise were only slightly greater than for frogs. There was no difference between parts of the brain. In 12 hr. the DNA fraction exchanges about 1 per cent. in cold-blooded and 3 to 5 per cent. in warm-blooded animals. Among warm-blooded animals the rate of exchange is greatest in spinal cord.

From 30 to 50 per cent. of phosphoprotein was exchanged in 12 hr. in cold-blooded and 100 per cent. in warm-blooded animals.—F. Billewicz.

8414

BERRY, W. K. **Phospholipid metabolism of skin.** *Nature*, 1956, **177**, 789–790. [Chem. Defence Exp. Establishment, Porton, Wilts.]

Portions of minced abdominal skin of rats were incubated at 34° C. with glucose or other substrates and 5 μC. $H_3{}^{32}PO_4$. At the end of 0·5, 1, 2, 3 or 4 hr. of incubation, lipids were extracted from the tissue and the specific radio-activity of the lipid P was estimated.

The specific radio-activity of the lipid P increased with time. As a percentage of that found after 3 hours' incubation in the presence of glucose the specific activity in the presence of succinate was 72, with glycerol 68, L-malate 45, DL-lactate 52, acetate 53, oleate 31, palmitate 44, stearate 42 and glucose plus iodoacetate 11; without added substrate it was 69.—G. A. Garton.

BURKE, W. T. and MILLER, L. L. **Biochemical changes during experimental carcinogenesis. 1. Amino acid metabolism in perfused livers of rats with cirrhosis and azo dye-fed rats.** *Cancer Res.*, 1956, **16**, 330–337. [Dept. Radiation Biol., Sch. Med. Dent., Univ. Rochester, N.Y.]

1. Rats in 3 groups were fed on a commercial diet, a synthetic diet to which was added per kg. 600 mg. 3′-methyl-4-dimethylaminoazobenzene or a diet to produce liver cirrhosis (Title 458, Vol. 11). The experimental diets were given for from 60 to 90 and from 150 to 200 days, respectively. After the rats had fasted for 18 hr. livers were perfused, by the technique already described (Abst. 3438, Vol. 24), with rat blood to which had been added mixtures of 8 essential and 11 non-essential amino acids, glucose and DL-lysine-HCl-6-^{14}C. Estimations were made of urea in blood and free α-amino acids in blood and liver, and ^{14}C was measured in CO_2 formed and in CO_2 derived during oxidation of protein precipitated from liver and plasma.

From their morphological structure the livers of rats getting the benzene derivative were concluded to be pre-cancerous; there was no evidence of formation of true hepatoma. Fatty infiltration had occurred in the cirrhotic livers.

Production of urea and clearance of α-amino acids from blood in 6 hr. by the pre-cancerous livers were about half the amounts by the normal livers; for the cirrhotic livers they were much less. Changes in the same directions took place in the oxidation of radio-active lysine. The proportions of lysine incorporated in liver and plasma proteins were greater in pre-cancerous than in normal animals; in those with cirrhosis incorporation was increased only for liver proteins. The final concentration of free amino acids was higher in pre-cancerous and cirrhotic than in normal livers.

The findings are discussed. Disturbance of metabolism of amino acids is thought to be the most likely explanation and is to be the subject of further study.—D. Harvey.

BABSON, A. L. **The rate of loss of labeled plasma proteins from the circulation of tumor-bearing rats.** *Biochim. biophys. Acta*, 1956, **20**, 418. [Radiation Res. Lab., Coll. Med., State Univ. Iowa, Iowa City.]

Labelled plasma, globulin or albumin was obtained from rats injected with leucine-^{14}C or tyrosine-^{14}C and infused into normal rats or rats with tumours. The radio-activity disappeared from the circulation twice as quickly in cancer-bearing as in normal rats, and it is suggested that plasma protein was being synthesised twice as fast in rats with tumours.—A. Hepburn.

4822

GUTMANN, H. R., FILBIN, D. and PETERS, J. H. **The action of 2-acetylaminofluorene on growth and liver composition of rats on low and adequate dietary sulfur.** *Cancer Res.*, 1956, **16**, 240–245. [Radioisotope Unit, Vèterans Admin. Hosp., Minneapolis, Minn.]

Weanling female littermate rats initially 20 or 29 days old were pair-fed as described earlier (Gutmann and Peters, *Cancer Res.*, 1953, **13**, 895), for 100 or 119 days. The basal diet with 11 per cent. casein was given alone or with 0·5 per cent.

2-acetylaminofluorene, extra casein to make 20 per cent., 0·25 per cent. DL-methionine, 0·2 per cent. L-cystine or 0·13 per cent. glycine or any of the latter with acetylaminofluorene.

Acetylaminofluorene with the 11 per cent. casein basal ration retarded growth by 26 per cent. in 119 days, but did not retard growth with 20 per cent. casein. Methionine, cystine or glycine did not prevent retardation of growth. The value of the extra casein is therefore not due to S amino acids. The liver was always enlarged when acetylaminofluorene was given, but especially with the higher protein intake or the supplements of cystine and methionine. Liver fat was significantly increased in all the experimental groups except the group with 20 per cent. casein, but was never more than 5 per cent. Glycogen was increased considerably and protein somewhat less.

FRACCARO, M. **A contribution to the study of birth weight based on an Italian sample.** *Ann. Human Genetics*, 1956, **20,** 282–298. [Galton Lab.]

This study, based on data from the University of Pavia maternity clinic, provides comparisons with the English study of Karn and Penrose (Abst. 5193, Vol. 21). The Italian babies were smaller and had shorter gestation, older mothers of higher parity, and higher mortality. In most respects, the trends and correlations resemble the findings of Karn and Penrose. The suggestion, attributed to Penrose, is made that the weight of the foetus may determine the length of gestation; this may account for the decline of the birthweight curve after term and the relatively short gestation in twin pregnancies. The influence of differential mortality at different birthweights on "natural selection" is discussed in mathematical terms. [As with many other studies based on hospital records, the data presented have to be taken at their face value. For example, gestation periods up to one year are introduced without comment. The effect of socio-medical selection for admission to hospital and social differences between the Italian and the English series are not considered.]

HOLFELDER, G. Körpergewichte von Säuglingen einer Grossstadt. (Untersuchungen an den Geburtsjahrgängen 1951–1953 der Stadt Frankfurt am Main.) [**Bodyweight of infants in a city. Studies of children born in the years 1951 to 1953 in the city of Frankfurt am Main.**] *Ztschr. Kinderheilk.*, 1956, **78,** 35–46. [Stadtgesundheitsamt, Frankfurt a.M.]

In all, there were nearly 50,000 weighings of 8347 infants (4252 boys, 4095 girls) at welfare clinics, nearly half the infants born in Frankfurt during the 3 years. Infants with any record of health disturbance, including digestive disturbances and infections, were excluded. For the first half-year weights are given weekly, for the second monthly; the numbers in each age group ranged from about 450 to 1000 or more. The mean weights at birth and 1 year for boys and girls were 3423, 3270 g. and 10,348, 9718 g. Average birthweight was doubled in the 17th and 18th weeks, respectively.

For closer study the infants were divided into 4 groups: those under 2500 g. at birth; those exclusively breast fed for 12 weeks and those not seen as late as this but exclusively breast fed when last seen; those partly breast fed, either wholly for a shorter time or partly all along; and those artificially fed and those for whom information on mode of feeding was lacking.

Infants of low birthweight were still behind at 1 year, by about 1000 g., but they doubled their birthweights early, in the 10th and 11th weeks.

No significant difference in weight was found between groups fed in different ways (the data are not reproduced). But the percentages discarded because of health disturbance differed: breast-fed, boys 1·02, girls 1·57; not breast-fed, 3·41, 4·37; partly breast-fed intermediate.

The weights for boys and for girls are plotted with those of Fierlings (*Thesis*, Greifswald, 1939), Hardtke (*Thesis*, Breslau, 1940, boys only), Gollnik (*Thesis*, Breslau, 1941, girls only), von Pirquet (*Ztschr. Kinderheilk.*, 1913, **6,** 253), Schlesinger (Abst. 3365, Vol. 3) and Stuart (in Mitchell and Nelson's "Textbook of Pediatrics", 5th ed., Saunders, Philadelphia, 1950). For boys the results surpass all the others, except von Pirquet's for the first few weeks, though they are generally only 200 to 300 g. higher than von Pirquet's. The lowest results are those from Breslau; those from the United States lie in the middle. Girls on the whole showed the same trends but the locality differences were smaller. None of the other authors found so early a date for the doubling of the birthweight.

Comparison of the breast-fed and artificially fed infants with those reported on earlier (not repro-

duced in detail) showed that the increase in weight gain was most striking in artificially fed infants and in breast-fed infants after the period of exclusive breast feeding.

The finding are considered to be against the idea of acceleration of growth in the first year of life.

LENZ, W. Die Bedeutung mütterlicher Faktoren für die Entstehung des Zwergwuchses. [**Significance of maternal factors in the origin of dwarfing.**] *Ztschr. Kinderheilk.*, 1956, **78,** 47–59. [Kinderklin., Univ. Hamburg, Eppendorf.]

Search of the records of the Eppendorf Klinik since 1951 revealed 23 children with pituitary dwarfism uncomplicated by thyroid defect, congenital malformation or other disorder, and 44 undersized children. When the ages of their mothers at their births were compared with those of mothers of 4000 unselected children, with an age distribution similar to that of the mothers of all children born in Hamburg in 1946–54, it was found that a significantly higher proportion of the mothers of the dwarfs and of the undersized were aged 30 or over, with a peak between 35 and 39 years. This was still true when the 2 classes were combined and first, second, third, and fourth and higher births were compared. When the mothers were classified in 5-year age groups an independent effect of parity of 4 or over was seen above the age of 25. Of 30 brothers or sisters of dwarfs, 22 were within the normal range of height. The social environment was on the whole satisfactory, never really bad, though some of the children who were merely undersized came from large families in poor surroundings.

Contrary to the findings of some authors on sporadic or endemic cretinism, 30 children with thyroid defects had mothers with an age distribution not significantly different from that of the control sample.

The results are discussed in conjunction with the literature on dwarfism and effects of high age of mother and high parity on the growth of children. It is emphasised that almost all children of elderly mothers are normal. The conclusion is that pituitary dwarfism cannot always be ascribed to heredity and its causes must lie in the intrauterine environment.

In a note added in proof it is admitted that in Hamburg the average age of mothers was higher during the war than before or after. This does not affect the findings, but may have something to do with the increased incidence of congenital malformations during and just after the war, generally ascribed to poor diet and mental strain.

TRULSON, M. F., COLLAZOS C., C. and HEGSTED, D. M. **Growth and development of Peruvian children. 1. Carquin and San Nicholás.** *Pediatrics*, 1956, **17**, 510–523. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston.] Spanish and Interlingua summaries.

1. Weight and height of 109 children were measured and X-ray studies of hand and wrist were made. Compared with standards for North American children the Peruvian children were, in general, below normal for age, especially in height. Developmental age (Wetzel) and skeletal age were retarded in relation to chronological age. As indicated by partial correlation coefficients skeletal age was not closely related to height, weight or developmental age. The diet and clinical status of children in these communities were reported earlier (Abst. 2269, Vol. 24; 1090, Vol. 25).

4833

BENJAMIN, K. M. Wuchsform und Blutkreislauf. [**Growth form and circulation of the blood.**] *Helv. paediat. Acta*, 1956, **11**, 24–44. [Tel Aviv.] French, Italian and English summaries.

By growth form the author means not constitutional type (leptosome or pyknic), but body build assessed by the ratio of cube root of weight to height. The " corpulence index " ranges from 138 for the infant to 105 for the adolescent of about 14 and is on the average 112 for a well proportioned adult.

Most of the paper deals with haemodynamics in relation to body build and with the adaptation of the circulation to different stages of development. The plump body build of the infant favours a uniform supply of blood, for nutrition and growth, the slim body build of the adolescent or adult favours rapid shifts of blood (adaptation for hunting and flight). A few pages are devoted to the relation between size and activity or muscular efficiency in the child and adult and in different species. The textbook statement that the greater activity or muscular efficiency of the smaller creature is explained by its relatively greater surface area and an energy exchange proportional to this is wrong. Kleiber (Abst. 4658, Vol. 17) has shown that the energy exchange rises as the 3/4 power of the weight, that is, faster than the surface (2/3 power of the weight). The smaller creature uses relatively less energy, because of the more favourable ratio of muscle strength to load borne. In the adult as compared with the child, this is partly counterbalanced by the greater proportion of muscle in the body.—W. M. Deans.

4834

BLODGETT, F. M., BURGIN, L., IEZZONI, D., GRIBETZ, D. and TALBOT, N. B. **Effects of prolonged cortisone therapy on the statural growth, skeletal maturation and metabolic status of children.** *New Engl. J. Med.*, 1956, **254**, 636–641. [Dept. Paediat., Harvard Med. Sch., Boston, Mass.]

Growth in height of children with adrenocorticovirilism, hypopituitarism, Addison's disease or allergy was inhibited by cortisone. Growth was suppressed in hypopituitarism by 4 to 20 mg. cortisone per sq. m. body surface daily and in allergy by 45 mg. In adrenocorticovirilism 35 mg. reduced growth to normal and 35 to 50 mg. tended to reduce rate of growth in height and skeletal maturation to below normal. Except in hypopituitarism, children whose growth was depressed showed a spurt when cortisone intake was reduced below the levels associated with inhibition of growth. Biochemical and electrocardiographic findings were normal except in 3 patients in whom treatment with cortisone was suddenly discontinued because of acute febrile illness.

VEREL, D., BURY, J. D. and HOPE, A. **Blood volume changes in pregnancy and the puerperium.** *Clin. Sci.*, 1956, **15**, 1–7. [Med. Unit, London Hosp.]

In 13 pregnant and 8 non-pregnant women simultaneous estimations of red cell volume and plasma volume were made with ^{32}P-labelled red cells and Evans Blue. The ratio of body haematocrit to venous haematocrit showed a much wider range in the pregnant women, 0·87 to 1·08, than

the more constant ratio of 0·9 to 0·95 found in non-pregnant women ; the estimation of blood volume from the measurement of either red cell or plasma volume may therefore involve considerable errors during pregnancy.

An increase in plasma volume above normal was found in all the pregnant subjects, but only in 2 was the red cell volume increased above normal non-pregnant limits.

Blood loss of 5 subjects at delivery was measured accurately by estimating shed Hb. Twelve hours after delivery there was a marked fall in red cell volume not explained by the puerperal blood loss ; in one woman 520 ml. of red cells had been removed from the circulation.—F. E. Hytten.

4838

STARK, G. and JUNG, W. Phosphatasen in der Placenta und ihren einzelnen Zellfraktionen. [**Phosphatases in the placenta and its cell fractions.**] *Arch. Gynäkol.*, 1955–56, **187,** 398–405. [Frauenklin, Univ. Mainz.]

Homogenates and cell fractions, namely, nuclei, mitochondria, and cytoplasm plus microsomes, from 50 fresh mature human placentae were tested for phosphatase activity at *p*H 5·6 and 9·8, and so were maternal and cord blood. Activity was highest in the mitochondria ; next came cytoplasm plus microsomes. The differences between the fractions were much greater for alkaline than for acid phosphatase. The activity of placental homogenate was about 50 times that of serum from maternal or cord blood.—W. M. Deans.

4839

HOLMBERG, N. G., KAPLAN, B., KARVONEN, M. J., LIND, J. and MALM, M. **Permeability of human placenta to glucose, fructose, and xylose.** *Acta physiol. scand.*, 1956, **36,** 291–299. [Södra Barnbordshuset, Wenner-Gren Res. Lab., Stockholm.]

In an unstated number of vaginal hysterotomies the rates of transfer across the placenta of glucose, fructose and xylose were calculated. The age of the foetus ranged from 15 to 22 weeks. The sugar was injected into a maternal vein and samples were taken from another vein and from the umbilical vein simultaneously 3 to 8 min. later. In other experiments sugars were injected directly into the foetal circulation.

The results are expressed as " apparent net transfer rates " and show that the transfer of glucose and xylose from mother to foetus was of the same order as that found for the guineapig and the sheep. The rate for fructose was much less.

F. E. Hytten.

4840

CHINARD, F. P., DANESINO, V., HARTMANN, W. L., HUGGETT, A. St. G., PAUL, W. and REYNOLDS, S. R. M. **The transmission of hexoses across the placenta in the human and the rhesus monkey** (*Macaca mulatta*). *J. Physiol.*, 1956, **132,** 289–303. [Dept. Embryol., Carnegie Institution of Washington, Baltimore, Md.]

The passage of glucose and fructose across the placenta was studied in 11 women and 9 monkeys. Foetal blood samples were taken at caesarean section, with the women under local anaesthesia, by delivering a loop of cord through a small uterine incision, and from the interplacental arteries in the monkeys. High blood values for glucose and fructose, average 90 mg. per 100 ml., were induced in the women, and ^{14}C-labelled glucose and fructose were administered to the monkeys.

" Glucose appears to pass freely across the primate placenta in both directions." The primate foetus appears to have very little blood fructose normally, up to 5 mg. per 100 ml., although in 4 samples it was between 10 and 20 mg. per 100 ml.

Fructose appears readily in the foetal circulation after infusion into the mother. It is suggested that the same carrier system operates for both sugars and that they can compete for it.

F. E. Hytten.

4841

HAYASHI, T. **Uric acid and endogenous creatinine clearance studies in normal pregnancy and toxemias of pregnancy.** *Amer. J. Obstet. Gynecol.*, 1956, **71,** 859–870. [Dept. Obstet. Gynaecol., Sch. Med., Temple Univ., Philadelphia, Pa.]

Single or consecutive estimations of uric acid clearance and blood uric acid were made on 181 pregnant women ; in 143 of them, endogenous creatinine and uric acid clearances were studied simultaneously. Patients omitted breakfast on the morning of test and drank 200 ml. water every half-hour to promote flow of urine. Urine was collected by indwelling catheter. The maximum renal clearances were usually calculated, and results were not adjusted for bodyweight or surface area.

In normal pregnancy (women admitted to the clinic for conditions which should not disturb renal function), averages for the periods before and after the 32nd week were : uric acid clearance, 18·4 and 13·0 ml. per min. ; endogenous creatinine clearance, 129 and 108 ml. per min. ; blood uric acid, 3·2 and 3·0 mg. per 100 ml. In pre-eclampsia, the corresponding values were 4·8 and 6·5, 63 and 99, 7·5 and 6·0. In essential hypertension they were 14·5 and 14·2, 114 and 128, 3·7 and 4·1. In essential hypertension with superimposed pre-eclampsia most averages were intermediate, and in unclassified " toxaemia " (excessive weight gain attributed to abnormal retention of fluid)

they resembled, on the whole, the averages for essential hypertension. The ranges were wide, so that the studies had limited prognostic or diagnostic value; but in pre-eclamptic patients on whom repeated studies were made, both uric acid and creatinine clearance remained low until pregnancy terminated, even with clinical improvement. A sudden decrease in these clearances was of some value in predicting pre-eclampsia in previously normal women and in those with fluid retention. In essential hypertension, creatinine clearance remained high during the last few weeks before delivery, instead of falling as in normal pregnancy or when pre-eclampsia became superimposed. It is suggested that the parallel changes in creatinine and uric acid clearances point to decreased glomerular filtration, rather than increased tubular reabsorption, as the cause of low uric acid clearance in pre-eclampsia.—A. M. Thomson.

4842

HEROLD, L. Kalium-Natriumuntersuchungen in Blut und Gewebe, ein Beitrag zur Frage der Transmineralisation in der Gestationsperiode. **[Studies on potassium and sodium in the blood and tissues; a contribution to the problem of transmineralisation during pregnancy.]** *Arch. Gynäkol.*, 1955–56, **187**, 388–397. [Geburtsh.-Gynäkol. Abt., Städt. Krankenhaus Düsseldorf, Benrath.]

By " transmineralisation " is meant a change in the distribution of electrolytes. Analyses were made of samples of smooth muscle from uteri removed from women of reproductive age, from uteri of normal pregnant women at caesarean section, and in the 9th or 10th month from one subject with pre-eclampsia and two with eclampsia; and of venous blood serum taken from the same subjects. The results were per cent. for 18 non-gravid women, serum K 20·5 ± 0·88 mg. and Na 314·8 ± 8·43 mg.; uterus muscle K 305·5 ± 11·63 mg. and Na 161·8 ± 8·88 mg. For women in late pregnancy the corresponding values were 20·2 ± 0·79 mg. and 273·1 ± 7·63 mg.; 238·6 ± 9·34 mg. and 206·3 ± 6·78 mg. Corresponding K : Na ratios were for serum 0·0653 and 0·0725 and for uterus muscle 1·885 and 1·157.

In 20 non-pregnant and 25 pregnant other women average serum and red cell values were: non-pregnant K 20·6 and Na 318·5, pregnant 20·3 and 276·8; non-pregnant K 421·3 and Na 116·7, pregnant 391·9 and 139·9 mg., and K : Na ratios were in serum 0·0652 and 0·0726 and in red cells 3·604 and 2·807.

For the toxaemic women the changes were in the same direction and greater than in the normal pregnant.

These changes are towards the values found in the foetus, infant and young child and it is suggested that such values for Na and K and the greater water content of the body are characteristic of higher metabolic levels and growth processes.—I. Leitch.

4843

PERRY, J. S. **Fecundity and embryonic mortality in pigs.** *J. Embryol. Exp. Morphol.*, 1955, **2**, 308–322. [Lab. Agric. Res. Counc., Compton, Berks.]

A study was made of 863 pigs, mostly sows discarded on account of " age, sterility, low fertility, poor milk supply or some other disability, or to make room for another animal in the breeding stock ". In most of them, in terms of ova shed, there was no evidence of infertility. They were thought to be representative of pig populations in general.

" Reliable " counts of corpora lutea were got from 352 pigs. The most frequent number in sows, for 2 ovaries, was 20, the spread from 10 to 38, the number increasing with age. For 27 gilts (non-parous pigs) the average was 13·6.

Counts of both corpora lutea and embryos were obtained from 85 sows and 19 gilts as follows: sows, corpora lutea 7 to 31, mean 19 [to nearest whole number]; embryos 1 to 23, mean 12; gilts, corpora lutea 2 to 21, mean 14; embryos 2 to 15, mean 10. From these data it is not possible to estimate embryo mortality, because litters lost in entirety and late losses are not shown. In 15 gilts pregnant between 17 and 40 days, the loss, as disappearance of shed ova, was 20·1 per cent.; in 37 sows, 36·9 per cent. In 99 pregnant animals, ova lost, as the difference between corpora lutea and embryos found, increased with number of corpora lutea from 26 per cent. for 9 to 14 to 42 per cent. for 22 to 31 corpora lutea. Losses rose also with length of gestation.—I. Leitch.

4844

WORM, M., MOHNIKE, G. and GRIMM, H. Tierversuche über die Beziehungen zwischen der Zuckerkonzentration in Fruchtwasser, maternem und fetalem Blut. **[Animal experiments on the relations between the sugar concentrations in amniotic fluid and maternal and foetal blood.]** *Ztschr. ges. exp. Med.*, 1956, **127**, 293–299. [Diabetikerheim, Garz, Rügen.]

For these experiments rabbits and hares were chosen as having haemochorial placentae, one per foetus, and individual amniotic sacs. On the 28th day of pregnancy, with urethane anaesthesia, the foetuses were exposed; glucose or insulin was injected into the mother and samples were taken at intervals of maternal blood from an ear vein, which did not differ from blood from pelvic vessels, of foetal blood from the jugular vein and of amniotic fluid. Sugar in foetal blood followed

changes in maternal blood with a lag such that, after glucose followed by insulin, foetal might exceed maternal blood sugar for as long as 30 min. Changes in amniotic fluid were slower and less in magnitude. The results are discussed with reference to fluctuations in the blood sugar of diabetic women at term.—I. Leitch.

FEASTER, J. P., HANSARD, S. L., OUTLER, J. C. and DAVIS, G. K. **Placental transfer of calcium in the rat.** *J. Nutrition*, 1956, **58,** 399–406. [Nutrit. Lab., Florida Agric. Exp. Stat., Gainesville.]

Seventy-two nulliparous rats aged 12 to 15 months, maintained on commercial rat pellets containing 1·38 per cent. Ca and 0·96 per cent. P, were mated and at different stages of gestation were given by mouth single doses of $^{45}CaCl_2$. The pregnant rats were killed 30 min. to 20 days after receiving the isotope and the foetuses and carcases were analysed for ^{45}Ca and total Ca content; excretions were analysed for ^{45}Ca.

The ^{45}Ca was found to cross the placenta and to be deposited in the foetus at all stages of gestation studied, namely, from the fourteenth to the twenty-second day. The amount of ^{45}Ca transferred from dam to foetus in a given length of time increased with increasing foetal age. In 30 min. an appreciable amount of the isotope was absorbed and transferred to the foetus. It is suggested that part of the Ca transferred to the foetus must have been derived from Ca previously stored in the maternal skeleton.—G. F. Garton.

4847

LOGOTHETOPOULOS, J. and SCOTT, R. F. **Active iodide transport across the placenta of the guinea-pig, rabbit and rat.** *J. Physiol.*, 1956, **132,** 365–371. [Dept. Pathol., Postgrad. Med. Sch., London.]

Pregnant guineapigs, rats and rabbits received by injection ^{131}I and radio-activity was measured in maternal and foetal serum 70 to 80 min. later. Blocking the binding of ^{131}I by the thyroid with propylthiouracil made no difference to the serum concentrations; the ^{131}I apparently remained in ionic form.

In guineapigs and rabbits the foetal : maternal serum ^{131}I ratio was from 1·5 to 5, but when sodium thiocyanate was given subcutaneously before the experiment, the ratio never reached unity. In rats the foetal : maternal ratio rarely exceeded unity and fell to 0·3 to 0·4 after thiocyanate.

A placental transport mechanism for iodide, inhibited by thiocyanate, is postulated.

DRYDEN, L. P., GLEIS, P. F. and HARTMAN, A. M. **Reproduction and lactation of rats fed glyceryl trilaurate-containing diets.** *J. Nutrition*, 1956, **58,** 335–339. [Dairy Husb. Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Beltsville, Md.]

Studies were made on female albino rats which had been reared by mothers which were transferred at parturition from a stock ration to one of 2 experimental rations. The first experimental ration consisted of sucrose 63·4, alcohol-extracted casein 25, salts 4·5, glyceryl trilaurate 5, methyl linoleate 1·7, fish liver oil 0·05 and vitamins 0·38 per cent.; the second differed only in that a commercial vitamin-free casein was used and the fish liver oil was replaced by synthetic vitamin A and calciferol. The rations and distilled water were supplied to appetite. In the first experiment the mothers with their young were given from parturition the first ration; the young were weaned at 21 days, reared to 77 days on the first ration and then mated to stock males. They were continued on the same ration until 2 litters had been carried to weaning, then they were divided into 2 groups, one given the second ration and the other maintained on the first ration and carried through 2 additional pregnancies and lactations. The second experiment was similar except that the animals were given the second ration throughout and were carried through 2 pregnancies and lactations.

Survival of young to weaning ranged from 78 to 94 per cent., as contrasted with none in work of Keane *et al.* (Abst. 5204, Vol. 21). There was no evidence of failure in any other aspect of reproduction or lactation.—G. F. Garton.

4849

SMITH, E. **Pregnancy in the little brown bat.** *Amer. J. Physiol.*, 1956, **185,** 61–64. [Dept. Anat., Coll. Med., Univ. Cincinnati, Ohio.]

Studies were made in 2 consecutive years on bodyweight changes and metabolism of 303 pregnant female bats of the species *Myotis lucifugus lucifugus*, and on the weights of all the newborn bats collected during 5 years. In this species the single pregnancy each year occurs in the spring just after the bat emerges from the inactivity of hibernation and begins feeding actively; pregnancy lasts from late April or early May until late June or early July. The weight of the mother increased exponentially with the weight of the foetus; the rate of increase differed with the year. At birth, the single offspring weighed on the average 28·8 per cent. of the mother's weight. The

oxygen consumption in pregnant bats rose from 0·08 c.c. per g. per hour to 0·34 c.c. as weight rose from 6·1 to 8·9 g., but the metabolic rate was always less than the expected rate for a non-pregnant mammal of the same weight. The total heat increment of gestation (Brody, Abst. 2077, Vol. 8) was about 2·2 Cal.—G. F. Garton.

GODIN, C. and WORK, T. S. **Biosynthesis of proteins. 4. The effect of intravenous peptides on casein synthesis in a lactating goat.** *Biochem. J.*, 1956, **63,** 69–71. [Nat. Inst. Med. Res., Mill Hill, London, N.W.7.]

For part 3 see Abst. 861, Vol. 26.

A fraction rich in lysine peptides, isolated from a partial acid hydrolysate of goat casein, was injected with lysine-^{14}C into a lactating goat. The ^{14}C in the peptides from the partial hydrolysis of the casein synthesised after 2 hr. was uniformly distributed. This indicated that peptides in the blood cannot be used for synthesis of casein without degradation to amino acids.—A. Hepburn.

REPRODUCTION: BIRDS

4852

FELDMAN, M. and WADDINGTON, C. H. **The uptake of methionine-S^{35} by the chick embryo and its inhibition by ethionine.** *J. Embryol. Exp. Morphol.*, 1955, **3,** 44–58. [Inst. Animal Genetics, Univ. Edinburgh.]

Fertile eggs were injected 17 to 18 hr. before incubation began with 0·1 ml. of a solution of DL-methionine labelled with ^{35}S, with radioactivity about 50 μC. per ml. After incubation for different periods the embryos were fixed and autoradiographs were made from whole embryos and sections.

In primitive streak or head process stages the uptake of ^{35}S by ectoderm was much greater than that by mesoderm. From the beginning of its differentiation, neural tissue had the highest incorporation of isotope, and later this was true especially of brain. At the somite stage mesoderm became more active than ectoderm, in the region of the neural groove.

Ethionine injected with labelled methionine reduced the amount of isotope incorporated by more than half. Development of embryos was retarded by ethionine and abnormalities were found. Retardation was prevented by larger amounts of methionine, but several abnormal embryos occurred. Glycine did not abolish the effect of ethionine.

Aspects of the effect of ethionine are discussed. D. Duncan.

ROMIJN, C. and VELTHUIZEN, J. Die Jodausscheidung im Hühnerei. [**The output of iodine in the hen's egg.**] *Arch. Geflügelk.*, 1956, **20,** 97–106. [Lab. Vet. Physiol., Reichsuniv. Utrecht.] English summary.

For an earlier experiment see Abst. 4729, Vol. 23.

Of 2 groups of 20 one-year-old hens in a laying battery, getting 140 g. of an all-mash ration daily in 2 equal feeds, one had 0·68 mg. I per kg. diet from the mineral mixture and the other had it raised to 7·79 mg. with Algit (seaweed meal); the daily intakes of I were 95 and 1091 μg. per bird, respectively. The eggs were found to contain 19·9 and 113 μg. I. The respective percentage distributions were yolk 60·3 and 78·3, white 7·0 and 4·7, membranes nil and 0·3, shell 32·7 and 16·8. Since most of the iodine in the yolk was soluble in water, it was assumed to be in inorganic form. Estimation of I in the droppings showed that these and the eggs accounted for all the iodine ingested.

The course of elimination of I in the egg at the start of the experiment was studied in the above groups and in another group of 20 hens given the same ration plus KI to raise the iodine content to 6·90 mg. per kg. diet. Little extra I appeared in the eggs till the fifth day, when there was a steep rise till the tenth day; this corresponds to the formation of the yolk in the ovary. The hens given Algit eliminated more I per egg than those given KI, but the eggs of the latter were smaller, and after about 200 days there was little difference between the groups in the total amount of I eliminated for the same weight of egg on a fresh basis.

Other experiments were made with hens which got iodine with the morning feed only, and grain in the late afternoon. In the first, 5 groups of 54 one-year-old hens had 1·5 mg. I per kg. diet (controls), 13·2, 51·6 or 72·9 mg. from Algit or 76·3 mg. from KI. In the other experiment 4 groups of 78 pullets 6 months old had 1·7 mg. I per kg. diet (controls), 26·6 or 52·9 mg. I from Algit or 56·3 mg. I from KI. Less I was eliminated by the younger birds, but variations were large, which may have been partly due to differences in age and breed.—W. M. Deans.

SENESCENCE

4854

CHINN, A. B., LAVIK, P. S. and CAMERON, D. B. **Measurement of protein digestion and absorption in aged persons by a test meal of I^{131}**

labeled protein. *J. Gerontol.*, 1956, **11,** 151–153. [Dept. Med., Sch. Med., Western Reserve Univ., Cleveland, Ohio.]

Studies were made on 12 subjects aged 72 to 88 years who showed no apparent defect in digestion and absorption of protein. Their thyroids were blocked by 45 minims of Lugol's solution administered daily for 3 days and, after an overnight fast, a freshly prepared test meal composed of 0·5 g. gelatine and 1 g. glucose per kg. bodyweight and 100 μC. ^{131}I-labelled albumin, all mixed in 200 ml. distilled water, was given to each subject. Oxalated blood samples were obtained fasting and 1, 2 and 3 hr. after the test meal; the radio-activity of the samples was measured and the total isotope content of the blood was calculated. Blood sugar and the radio-activity of faeces were estimated also.

The rate of digestion and absorption of protein and their extent in 72 hr. were not significantly different in the aged subjects and in younger subjects studied previously (Abst. 2027, Vol. 24).

CALET, C. and JACQUOT, R. Rôle physiologique des antibiotiques comme facteurs de sénescence. [**Physiological role of antibiotics as senescence factors.**] *C.R. Acad. Sci.*, 1955, **241,** 991–993.

The authors' earlier work with rats given aureomycin (see Absts. 380, 3102, Vol. 24; 5128, Vol. 25) is summarised and that of other workers is quoted in support of the view that the changes produced by the antibiotic are those of senescence. Data are presented to show that with aureomycin in the diet the amount of deoxyribonucleic acid, as mg. P, falls from 0·20 to 0·15 per g. liver tissue and from 0·80 to 0·67 in the whole organ.

EXPERIMENTAL STUDIES OF IMMUNITY AND MICRO-ORGANISMS

4856

HALLIDAY, R. **The termination of the capacity of young rats to absorb antibody from the milk.** *Proc. Roy. Soc.* [*B*], 1956, **145,** 179–185. [Agric. Res. Counc. Unit Embryol., Dept. Zool., Univ. Coll. N. Wales, Bangor.]

Young rats were suckled for more or less than the usual time by transferring them to foster-mothers at a different stage of lactation from their own mothers or by premature introduction to solid food by hand feeding. At the end of the experiment their capacity to absorb antibodies was tested either by allowing them to suckle females immunised against *Salmonella pullorum* or by introducing immune serum by stomach tube.

Rats from 6 to 9 days old readily absorbed antibodies from the milk of fostermothers at 21 to 25 days of lactation. Rats aged 21 days or more were unable to absorb antibodies from the milk of fostermothers at earlier stages of lactation. Milk from mothers at 16 to 23 days of lactation did not prevent rats aged 17 days or less from subsequently absorbing antibodies, *i.e.*, there did not appear to be a substance in the milk in late lactation which influenced the capacity of the young rat to absorb antibodies. The time at which solid food was given, either as early as 12 days or as late as 24 days, did not affect the time at which absorption of antibodies ceased. Sucking rats could be immunised by injection of *Salmonella pullorum* at about 10 days of age, but not at 2 or 3 days; quite high titres of circulating antibody were developed before the age when absorption of maternal γ-globulin ceased.—D. Duncan.

PETUELY, F. Ist eine quantitative Erfassung der in Säuglingsstühlen vorhandenen Bifiduskeime durch Züchtung möglich? Ein Selektivnährboden für den Lactobacillus bifidus. [**Is the quantitative estimation of *bifidus* bacilli possible by culture from infants' stools? A selective medium for *Lactobacillus bifidus*.**] *Ztschr. Kinderheilk.*, 1956, **78,** 28–34. [Biochem. Lab., Univ. Graz.]

The medium contained in each 50 ml., at *p*H 6·4, lactose 3·5 g., K_2HPO_4 0·25 g., ammonium acetate 0·2 g., Tween 80 0·1 g., cystine 20 mg., Ca pantothenate 40 μg., biotin 0·4 μg., $MgSO_4 . 7H_2O$ 12·5 mg., $FeSO_2 . 7H_2O$ 0·625 mg., $MnSO_4 . 4H_2O$ 0·425 mg., NaCl 0·625 mg. and vitamin C 1 g. This was mixed at 60° C. with an equal volume of 4 per cent. agar solution and plates were made. Cultures had to be kept under CO_2; if the medium was heated above 60° C. or allowed to stand in air for more than 1 or 2 hr. the vitamin C oxidised and the plates were useless. Stool samples were diluted in physiological saline to 1 in 10^6 or 10^8. On this medium quantitative estimation of *Lactobacillus bifidus* in the stools could be made.

Three types of colony were obtained, but the type had no relation to breast or artificial feeding. The numbers were related to the *p*H of the stools; the greatest numbers were at *p*H 6 to 7.

D. Duncan.

GYLLENBERG, H., ROSSANDER, M. and ROINE, P. **Effect of the fatty acids of human milk and**

cow's milk on intestinal lactobacilli. *Acta paediat.*, 1956, **45,** 147–160. [Dept. Nutrit. Chem., Univ. Helsinki.] French, German and Spanish summaries.

Strains of *Lactobacillus acidophilus* and *L. bifidus* isolated from faeces of rats and of infants, respectively, were grown in basal media to which fatty acids were added, and after a fixed incubation period growth was measured by titration of the lactic acid produced.

With *L. acidophilus* the optimum amount of oleic acid to stimulate growth was about 1 mg. per ml., and of linoleic acid 0·2 mg. per ml. or less. Myristic, palmitic and stearic acids increased growth to a less extent, and were best in a concentration of about 1·5 mg. per ml. In amounts varying from 0·2 to 2·5 mg. per ml. propionic, butyric and caproic acids were without effect, and capric and lauric acids were inhibitory even in the presence of oleic acid. With *L. bifidus* propionic, butyric and caproic acids were without effect and all other acids tested were inhibitory in the above range of concentration.

The inhibitory effect of some acids upon both organisms was reversed to some extent by the addition of 2 mg. per ml. of Tween 80, and by the proteins of skimmed human and cow's milk.

A growth-stimulating effect of human milk, particularly if it had been heated to a high temperature, for *L. acidophilus* was thought to be due to the unsaturated fatty acids which it contains.

TURBA, F., HÜSKENS, G., BÜSCHER-DAUBENBÜCHEL, L. and PELZER, H. Einbau von S^{35} und C^{14} in Torulazellen; biologische Halbwertszeit von Glutathion. [**Incorporation of ^{35}S and ^{14}C into torula cells: biological half-life of glutathione.**] *Biochem. Ztschr.*, 1956, **327,** 410–421. [Inst. Org. Chem., Univ. Mainz.]

Earlier work showed how ^{14}C is built in succession into amino acids, peptides and protein in torula cells (Abst. 2192, Vol. 26). Similar experiments with ^{35}S are described. Technique and tests of methods for separation and purification of the radio-active compounds produced are described.

^{35}S is rapidly built into first acid, then neutral and finally basic fractions of low molecular weight; the predominance of acid fractions was striking. Most, but not all, acidic peptides contained sulphur amino acids. Incorporation of ^{35}S into glutathione was demonstrable in a fraction of a second and activity of glutathione had a maximum at about 90 sec. To estimate the half-life of glutathione the slower and less easy method with ^{14}C was preferred. The experiments and calculations are shown in detail. The half-life of glutathione in yeast cells is 22 ± 2 min., which is much less than that measured in mammalian tissues. Implications for protein metabolism are discussed.

I. Leitch.

4861

MICHEL, M. and FRANÇOIS, A. C. Influence de la chlortétracycline sur les decarboxylases de la flore intestinale du porc. [**Effect of chlortetracycline on the decarboxylases of the intestinal flora of the pig.**] *C.R. Acad. Sci.*, 1956, **242,** 1770–1772.

The intestinal flora of the pig can cause decarboxylation of the amino acids of the feed. It was shown *in vitro* that glutamic and aspartic acids were most affected, then arginine, tryptophan and alanine. Methionine, ornithine and lysine were only slightly affected. Aureomycin (chlortetracycline), 10 μg. per ml., almost completely inhibited decarboxylation and the consequent formation of amines. It is suggested that this modification of decarboxylation and of the deamination process previously reported (see Abst. 3997, Vol. 25) are part of the mechanism by which growth of pigs is increased by antibiotics.—T. D. Bell.

4862

GRIMBERGEN, A. H. M. De invloed van antibiotica op de darmflora. (Literatuuroverzicht en eigen onderzoek.) [**Effect of antibiotics on intestinal flora. Review of literature and original studies.**] *Tijdschr. Diergeneesk.*, 1956, **81,** 549–568. [Inst. Mod. Veevoeding "De Schothorst", Hoogland.] English, French and German summaries.

Results reported by many workers in several countries on the influence of antibiotics on the bacteria of chickens' intestines vary widely, probably because of dissimilarity of methods. The author's own tests showed that lactobacilli developed resistance to penicillin after 6 days; and *Bacterium coli* to terramycin after 3 weeks. Terramycin also caused resistance to aureomycin, but not to chloramphenicol. In a subsequent test resistance was not produced by terramycin, but by

introduction of resistant *Bact. coli* in the feedingstuffs. Resistance may be due to alteration in bacterial metabolism, selection of resistant bacteria in the presence of antibiotics or increased propagation of resistant mutants in the presence of antibiotics.

Antibiotics have been widely used in feedingstuffs in the United States and so far no harmful effect has been reported. This does not mean that there has been none or that none will develop in the future. The occurrence of cross-resistance emphasises the need for caution, as the curative effect of antibiotics may be lost by their use in feedingstuffs.—M. Eddison.

4863

BAUMAN, H. E. and FOSTER, E. M. **Characteristics of organisms isolated from the rumen of cows fed high and low roughage rations.** *J. Bacteriol.*, 1956, **71,** 333–338. [Dept. Bacteriol., Univ. Wisconsin, Madison.]

Two groups of 3 cows had rations high in grain and in roughage, respectively, and the predominant types of rumen bacteria were investigated.

Serial dilutions of rumen contents were made in 9-ml. quantities of broth containing trypticase, phytone, cysteine, glucose and mineral salts. Anaerobic and reducing conditions were maintained under nitrogen. The highest dilutions showing growth on incubation under these rather selective conditions usually contained only one morphological type of bacterium, which was purified in agar shake cultures.

From 13 rumen samples of cows on the high-roughage ration 13 rods were isolated at limiting dilution, which all resembled *Lactobacillus bifidus*. The 9 isolates from separate rumen samples from the cows on the high-concentrate ration were all Gram-positive cocci, considered to resemble *Pediococcus* rather than the *Streptococcus bovis* previously described. The characteristics of these organisms, including fermentation tests and fermentation products from glucose, are given.

J. C. Appleby.

4864

LODGE, J. R., MILES, J. T., JACOBSON, N. L. and QUINN, L. Y. **Influence of chlortetracycline on in vitro cellulose digestion by bovine rumen microorganisms.** *J. Dairy Sci.*, 1956, **39,** 303–311. [Dept. Animal Husb., Iowa Agric. Exp. Stat., Ames.]

Twenty lactating dairy cows and 4 calves 4 months of age were used. Half had received aureomycin from an early age. Half the cows now got 240 mg. aureomycin each daily and half the calves 80 mg.

Rumen contents were withdrawn by stomach pump ; in the artificial rumen those from the cows given aureomycin digested only 73 per cent. of cellulose, those from the untreated cows 85 per cent. With calves the corresponding values were 58 and 78 per cent.

When aureomycin content was estimated in rumen inocula of the treated cows, withdrawn 16 hr. after the supplement was given, 0·08 μg. per ml. was found ; after 4 hr. the value was 0·22 μg. The calves were given their supplement in 2 equal parts, one with each feed. The level of aureomycin in the rumen 2 hr. after receiving half the supplement, *i.e.*, 40 mg., was 0·22 μg. per ml.

When 2·4, 1·6, 0·8 or 0·4 μg. aureomycin was added to the digestion medium, digestion of cellulose by the rumen micro-organisms of the cows not given aureomycin was inhibited; the inhibition was much less in cows given aureomycin.

It was shown that bacterial counts are affected by supplements of aureomycin, but the depression found initially in some types is lost when the micro-organisms have become adjusted.—T. D. Bell.

4865

LAMBERT, M. R. and JACOBSON, N. L. **The effect of chlortetracycline feeding on *in vitro* cellulose digestion by rumen microorganisms.** *J. Animal Sci.*, 1956, **15,** 509–514. [Iowa Agric. Exp. Stat., Ames.]

See above Abst.

4866

BELASCO, I. J. **The role of carbohydrates in urea utilization, cellulose digestion and fatty acid formation.** *J. Animal Sci.*, 1956, **15,** 496–508. [Polychem. Dept., E.I. du Pont de Nemours and Co., Inc., Du Pont Exp. Stat., Wilmington, Del.]

When starch, xylan and pectin in equal amounts were used as sources of energy in studies *in vitro*, utilisation of urea by rumen micro-organisms was improved. The starch was more effective than the other sources, and half quantities of starch and either xylan or pectin were equal to starch alone. Fatty acid production was the same with all these sources of energy.

Cellulose was inferior to starch in aiding utilisation of urea, digestion of cellulose and production of fatty acids. Dextrose was superior to cellulose in producing fatty acids. Cellulose was digested better alone than with high levels of dextrose. Starch, dextrose and cellulose, at high levels, influenced the proportions of butyric, propionic, valeric and acetic acids in the total fatty acids produced.—T. D. Bell.

MISCELLANEOUS FEEDING EXPERIMENTS

4867

LE MAGNEN, J. Hyperphagie provoquée chez le rat blanc par altération du mécanisme de satiété périphérique. [**Hyperphagia induced in the white rat by alteration in the peripheral satiety mechanism.**] *C.R. Soc. Biol.*, 1956, **150,** 32–35.

For 32 days 8 adult rats received for 2 hr. each morning a complete synthetic ration and for 2 hr. each evening stock biscuits (Sorolabo). The synthetic ration contained on different days for each rat citral, eucalyptol, benzyl acetate or benzaldehyde. The amount eaten was recorded. Later the rats received diets containing each substance for 30 min. in the morning in a different order, and this was repeated every second day for 6 tests, and in the intermediate days one of the rations was given for the whole 2 hr.

The rats ate on the average 72 per cent., range 43 to 170 per cent., more on the days when all 4 rations were given in succession than they did when only one was offered. It is concluded that the frequent change of olfactory stimulus provoked hyperphagia. Satiety was achieved much more rapidly with the single diet, and little was eaten after the first hour. Change in the olfactory stimulus renewed the appetite, but consumption still declined in successive half-hours. The peripheral stimulus of the new odour to some extent overcame the mechanism of satiety.—D. Duncan.

4868

LE MAGNEN, J. Rôle de l'odeur ajoutée au régime dans la regulation quantitative à court terme de la prise alimentaire chez le rat blanc. [**Effect of odour in the diet on the quantitative short-time regulation of food intake in the white rat.**] *C.R. Soc. Biol.*, 1956, **150,** 136–139.

Nine male rats, of average weight 150 g., caged individually, were fed as described in the preceding Abst. The amount of synthetic feed eaten was ascertained daily and is shown graphically. After 24 days, during which the amount consumed was fairly steady and rate of weight gain normal, the rats in 3 subgroups of 3 had, per 100 g. synthetic diet, 0·4 ml. citral, 0·2 ml. eucalyptol or 0·2 ml. benzyl acetate for 14 days, then for 2 days the amounts of scented substance were reduced to one-fifth, for the next 2 double the original amounts were added and finally for 6 days the feed was again given unscented.

Benzyl acetate did not affect consumption of the synthetic feed ; rats given eucalyptol and one of the rats given citral ate significantly less of it for 2 or 3 days, but the effect then disappeared. Dilution or concentration of the scented substance had no significant effect. On its removal, 7 of the 9 rats ate significantly more, but after 3 days their consumption reverted to that of the fore-period.

The results are considered to show that in the regulation of food intake scent acts to limit rather than to stimulate.—W. M. Deans.

ADRIAN, J., PERISSÉ, J. and JACQUOT, R. Intérêt et signification de la farine d'arachide comme aliment de protection du noir africain. Étude expérimentale. [**Interest and significance of groundnut meal as protective food for the African native. Experimental study.**] *Ann. Nutrit. Alimentation*, 1956, **10,** 3–10 (Mem.) [Lab. Biochim. Nutrit., C.N.R.S., Bellevue.]

Ten groups of 8 weanling rats, average weight 34 g., were used in a 2-month experiment to test the feasibility of supplementing poor African diets based on millet, maize or cassava with groundnut meal and possibly small quantities of hydrolysed fishmeal. The rats had food and water to appetite. All diets included red palm oil, containing 0·14 per cent. carotene, 5, Osborne Mendel salt mixture 1·5 and $CaCO_3$ 0·5 per cent., and vitamin D was supplied. Apart from these, the control diet consisted of maize starch 72, casein 18, cellulose 2 and a mixture of B vitamins 1 per cent. Diets 1, 2, 3, intended to represent poor African diets, had whole millet, yellow maize or whole cassava meal 90, maize starch 3 per cent. Diets 4, 5, 6, 7 had millet 75, supplemented with maize starch 17·4 and DL-lysine 0·6, or maize starch 8 and groundnut meal 10, or groundnut meal 18, or groundnut meal 15 and enzymically hydrolysed fishmeal 3 per cent. Diets 8 and 9 were the same as diet 7 except that millet was replaced by maize or cassava.

None of the experimental rats grew as well as the controls. Best total weight gains were with millet plus groundnut meal and hydrolysed fishmeal, maize with the same supplement, and millet plus 18 per cent. groundnut meal. Best gains per g. protein ingested were with millet plus lysine, and maize or cassava plus groundnut meal and hydrolysed fishmeal. With diets 1 and 2 weight gains were trifling, and all the rats on diet 3 lost weight and died.

It was concluded that a supplement of groundnut meal 15 and hydrolysed fishmeal 3 per cent. could balance African diets in respect of protein. Since the average human consumption of millet is estimated at 600 g. daily, this would mean 90 g. groundnut meal and 18 g. fishmeal, which might not be acceptable, for cost or other reason ; but

even 60 g. groundnut meal would have a worthwhile effect. Standards of composition would be required.—W. M. Deans.

SZKIŁŁĄDZIOWA, W., RUDOWSKA-KOPROWSKA, J. and MUSZKATOWA, B. Wyniki badán nad wartością biologiczną białek zestawów kulinarnych oznaczoną rożnymi metodami. [**Estimation of the biological value of proteins in meals by different methods.**] *Rocz. Państwowego Zakł. Hig.*, 1956, **7**, 141–162. Russian and English summaries.

The biological value of meals served in institutions was measured in experiments with rats by the methods of Osborne, Mendel and Ferry (*J. Biol. Chem.*, 1919, **37**, 223), of Carpenter and Porter (Title 1360, Vol. 23) and of Harrison and Long (Abst. 717, Vol. 16). The results were compared with the chemical score of the diets (Block and Mitchell, p. 249, Vol. 16). Agreement was good with the results for the first method if the diet was a mixed one, less good if much of it consisted of cabbage or wheat flour. The deviations were still greater for the second and third methods in that order. [From English summary.]

D. Harvey.

ALLEGRETTI, N. and GABRIĆ, D. Über die willkürliche Aufnahme von Aminosäuren bei Ratten. [**Voluntary intake of amino acids by rats.**] *Naturwissenschaften*, 1956, **43**, 135–136. [Physiol. Inst., Med. Fac., Univ. Zagreb.]

In continuation of experiments on the selection of salt solutions by rats exposed to metabolic stress (Gabrić and Allegretti, *Liječn. Vjesn., Zagreb*, 1955, **77**, 204 ; *Pflügers Arch.*, in the press), 2 groups each of 6 rats on an ordinary diet had a choice of *M*/6 sodium glutamate, *M*/6 glycine or tap water to drink. Rats in one group each had a daily injection of 0·4 unit insulin, those of the other, controls, an injection of saline, for 6 days. Rats given insulin drank slightly more than the controls ; about 20 per cent. of the fluid taken by the controls was water and the rest equally divided between sodium glutamate and glycine, but the rats given insulin, contrary to expectation, drank much more glycine and sodium glutamate and hardly any water.—W. M. Deans.

4872

WITTE, S., BÜNTE, H. and KIMBEL, K. H. Untersuchungen über enterale Antibiose bei der Ratte. [**Studies on intestinal antibiotics in the rat.**] 9. Veränderungen der Blutgerinnungsfaktoren durch Tetracyclinderivate. [**9. Changes in blood coagulation factors produced by tetracycline derivatives.**]

FISCHER, W., KIMBEL, K. H. and HEINKEL, K. 10. Das Verhalten der Aktivität von Lipase und Diastase des Serums unter oralen Chlor- und Oxytetracyclingaben. [**10. Effect of chlortetracycline and oxytetracycline by mouth on lipase and diastase activity in the serum.**] *Ztschr. ges. exp. Med.*, 1956, **127**, 160–167 ; 188–202. [Med. Klin., Univ. Erlangen.]

For part 8 see Abst. 3127, Vol. 26.

9. Treatment of rats with 100 mg. oxytetracycline (terramycin) per kg. bodyweight for 4 weeks reduced coagulation factors V and VII, and increased prothrombin time by about 50 per cent. ; aureomycin had no effect. In such rats which also had Marcumar (Roche), *i.e.*, 3-(1′-phenylpropyl)-4-hydroxycoumarin, 500 mg. vitamin K_1 per kg. removed its effect but not that of terramycin. Hence it was concluded that the effect of terramycin is not due to lack of vitamin K arising from a change of intestinal flora.

10. Previous findings (Absts. 5271, 2215, Vol. 25) that antibiotics improved absorption of fat and retarded uptake of carbohydrate suggested investigation of their effect on lipase and diastase. Because of the difficulties of studying these enzymes in the digestive tract *in vivo*, recourse was had to studying them in the blood. The mean lipase activity of the blood of 23 rats given 25 mg. chlortetracycline (aureomycin) daily for 30 days was little over half that of 132 untreated rats of the same age. In 4 rats given terramycin, no effect was found. Neither antibiotic significantly affected blood diastase.

The activity of lipase and diastase in human serum *in vitro* was reduced when either antibiotic was added.—W. M. Deans.

4873

GARCIA, J., KIMELDORF, D. J., HUNT, E. L. and DAVIES, B. P. **Food and water consumption of rats during exposure to γ-radiation.** *Radiation Res.*, 1956, **4**, 33–41. [Div. Biol. Med., U.S. Naval Radiol. Defence Lab., San Francisco, Calif.]

Young male rats were exposed to γ-radiation for 8-hr. periods under conditions which are described and which gave a total dose of 75 r per exposure. Control animals were littermates kept under similar conditions with sham exposure. Exposures were 8 in number at intervals of 1 week and there were 3 experiments. Conditions in the second and third were identical except that water was withheld during alternate periods of exposure. Bodyweights of the rats were recorded.

In all 3 experiments amounts of both food and water consumed during each exposure were less for treated than for control animals. The difference appeared during the first exposure and, for water, became greater as the number of exposures

rose. In the second and third experiments the difference in food eaten by the groups also increased with the number of exposures, but in the first experiment it did not alter. Changes in bodyweight reflected these differences in intakes of food and water; control rats gained weight and treated animals lost several g. during each exposure.

Measurements begun in the first experiment 1 hr. after the end of exposure showed that the groups did not differ in the amount of food eaten; the amount of water drunk by the treated rats was greater by an amount which increased progressively with the number of exposures.

It is suggested that radiation produces these effects by an action on gastro-intestinal function during exposure.—D. Harvey.

4874

REINIUS, L. **Growth failure caused by mild heat treatment of the diet.** *Acta physiol. scand.*, 1956, **35,** 265–271. [Vet. Coll., Helsinki.]

Groups of rats were weaned at 21 days of age and then given, to appetite, water and a diet of whole wheat meal 35·5, potatoes 35·5, whole milk powder, 12·5, minced beef 8, sucrose 4·4, lard 3·6 and NaCl 0·5 per cent. Most of the water in the diet was evaporated at 50° to 60° C.; the mixture lost about one-third of its weight in the process. It was then finely ground and a mixture of vitamins of the B group and vitamin K was added; this diet was given to control animals. The heated diet, which was given to the experimental animals, was prepared from the basal diet by keeping it in layers $\frac{1}{2}$ in. deep in an oven at 140° C. until it developed a slightly brown colour and a palatable taste, which took 30 to 40 min. During the heating the layers were turned over every 10 min. Before use the heated diet was supplemented with the same vitamin mixture as the unheated diet. The rats on both diets received 1 drop of cod liver oil weekly.

The heated diet caused total cessation of growth of the rats. Growth was restored by addition of casein or lysine; addition of leucine, methionine, histidine, vitamin B_{12} or sucrose was without effect.—G. F. Garton.

4875

GRIFFIN, C. A. and THOMPSON, W. R. **Studies of prepared feeds in relation to Salmonella infection in laboratory animals. 2. Reproduction and growth of mice on heated and unheated commercially prepared feeds.** *Amer. J. Vet. Res.*, 1956, **17,** 311–317. [Div. Labs., New York State Dept. Health, Albany, N.Y.]

Part 1 appeared in *J. Amer. Vet. Med. Assoc.*, 1952, **121,** 197.

2. Three commercial mouse feeds, the composition of which is given, were studied. For some groups of mice they were heated in bags to from 210° to 220° F. for 30 min. in dielectric ovens, or heated under a vacuum in an autoclave to a minimum of 100° C. for 30 min. Other groups had unheated feeds. The groups were large, up to 20 families of 1 male and 5 females, and were studied for 3 generations.

There was some difference in reproductive performance in favour of one of the 3 feeds, but no difference attributable to heating.—D. Duncan.

4876

DE GROOT, A. P. and ENGEL, C. **The effect of commercial sterilization on the nutritive value of milk as determined in experiments with rats and baby pigs.** *J. Dairy Res.*, 1956, **23,** 257–268. [Central Inst. Nutrit. Res. T.N.O., Utrecht.]

The effect of heat treatment on the quality of milk protein was studied. Biological values by the Mitchell method, using balance experiments with rats, were 87·0, 88·0 and 85·1 for raw, pasteurised and sterilised milk, respectively, and the digestibilities were 96·8, 96·3 and 94·4. When the milks were given to protein-depleted rats the average liveweight gains in 5 days were 27·7, 26·3 and 22·9 g., respectively. In a growth experiment with rats the differences in performance on the 3 milks were very small. In growth experiments on pigs weaned at 1 to 4 days of age the average weight gains on sterilised milk were 97, 95, 98 and 98 per cent. of those on pasteurised milk, but the differences were ascribed partly to more difficult adaptation and to a smaller intake of milk solids on the sterilised milk.

None of the differences observed was statistically significant, and the experiments failed to demonstrate a significant decrease in the nutritive value of milk caused by sterilisation according to the Stork procedure.—I. A. M. Lucas.

4877

SARETT, H. P. and SNIPPER, L. P. (with SCHNEIDER, D. L.) **Effect of adding carbohydrate to milk diets. 1. Growth and body composition. 2. Water restriction.** *J. Nutrition*, 1956, **58,** 529–542; 543–555. [Mead Johnson Res. Labs., Evansville, Ind.]

1. One of 6 groups of 10 male weanling rats was fed for 6 weeks on a diet of 99·5 per cent. powdered whole milk and 0·5 per cent. minerals and vitamins. The protein content was 24·4 per cent. The other groups were given 66·2 per cent. powdered milk and 33·3 per cent. carbohydrate, which reduced protein content to 16·2 per cent. Average weight gain was significantly greater with sucrose in the diet than with glucose or dextrin and was about the same as with milk alone. There was no significant difference in average weight gain between

groups given glucose, dextrin and starch. With lactose weight gain was significantly less than in any other group. There was no significant difference in energy intake between groups. Efficiency of food utilisation on the lactose diet was significantly lower than on other diets; between the other diets there was no significant difference. Water intake was significantly higher in animals on milk alone than on the diets with added carbohydrate. The concentration of lipid in the carcases of animals on diets with added carbohydrate was higher than in animals on milk alone. Protein content of carcases was about the same for all groups.

Data on liver, kidney and adrenal weights, relative to bodyweight, protein and lipid content of liver, ascorbic acid and cholesterol content of adrenals are tabulated. Relative kidney and adrenal weights were highest in the lactose group. This group also had relatively large livers, as had the dextrin group.

2. In the previous experiment animals on a diet of powdered milk drank 25 to 30 per cent. more water than those on diets with added carbohydrate. The effect of water restriction was investigated in weanling rats given the powdered milk diet and in rats given starch in place of one-third of the powdered milk. All rats were given water to appetite for 2 weeks. For the remaining 4 weeks each group was subdivided into 3 groups of 10 given 100, 80 and 60 per cent. of their previous water intake. Water restriction led to curtailment of food intake of rats in both groups, less in the starch group. On both diets water restriction resulted in reduced weight gains, fall in body lipid, increase in relative size of kidneys and adrenals and decrease in relative size of liver. Composition of liver and carcase was not much affected by water restriction. At all levels of water intake, weight gain per g. protein consumed was higher on the starch diets.—F. C. Aitken.

4878

MILLER, D. S. **The nutritive value of fish proteins.** *J. Sci. Food Agric.*, 1956, **7**, 337–343. [The Crookes Laboratories Ltd., 37–43 Gorst Rd., Park Royal, London, N.W.10.]

Nutritive values of some commercial fishmeals and of other laboratory preparations of cod were tested by estimation of the net protein utilisation (see Abst. 1993, Vol. 26). For the first group of 10 samples the range was from 33·1 per cent., for an oily fishmeal suspected of having been heated strongly during manufacture, to 68·3 per cent. for a meal from South Africa. The value for the meal used in the FAO experiment in Chile (*FAO Memorandum*, 1954, **3**, No. 9, 4) was 67·0 per cent. For the second group of products, either meals or extracted proteins, 27 values are tabulated; the highest was 83·0 per cent. for a product for which the drying temperature had not exceeded 50° C., the lowest were 43·0 and 40·0 per cent. for extracted proteins with 9 and 17 per cent. moisture, respectively, heated for 24 hr. [temperature not stated]. Impairment was the result of the Maillard reaction at the high temperature. The net protein utilisation was not affected by wet storage of the fish for 7 days or storage of the extracted proteins, wet for 4 or 8 days or dry for 100 days.

In further experiments with rats methionine was shown to be one, but probably not the only, limiting amino acid.—D. Harvey.

4879

HUTCHINSON, J. B., MORAN, T. and PACE, J. **Nutritive value of the protein of white and wholemeal bread in relation to the growth of rats.** *Proc. Roy. Soc.* [*B*], 1956, **145**, 270–279. [Res. Assoc. Brit. Flour Millers, Cereals Res. Stat., St. Albans, Herts.]

Wholemeal and 70 per cent. extraction flour were milled from the same sample of Manitoba wheat and baked into bread with yeast. The bread was dried and powdered to crumb. The white bread crumb formed 80 per cent. by weight of the basal diet. The other ingredients were arachis oil 5, skimmed milk powder 4, salt mixture 4, choline chloride 0·2, liver powder 0·4 and sucrose 6·4 per cent. In the wholemeal diet the percentage of crumb was such that it provided the same quantity of N as 80 per cent. of white crumb; sucrose was adjusted accordingly. In some experiments 10 per cent. potato powder, or an amount of steamed potato equivalent in N content to the potato powder, replaced an equivalent amount, in terms of N, of crumb. The lysine contents of the whole meal and white crumb diets were estimated. In one experiment the lysine content of the white crumb diet was raised by the addition of lysine to that of the wholemeal crumb diet. In another experiment the lysine contents were brought to 1 per cent. by addition of lysine to both diets, and in a third experiment the lysine content was 0·8 per cent. and the skimmed milk powder was replaced by an amount of crumb equivalent in terms of N. All diets were supplemented with vitamins of the B complex, vitamins A and D and α-tocopherol. Groups of weanling and 8-week-old rats were fed on these diets and mean weight gains, food consumption and gains per g. N consumed are tabulated.

In weanling rats wholemeal bread gave better growth than did white bread, even when the diet included skimmed milk powder and potato. In older male rats the differences were less and in older female rats the differences were not significant. Addition of lysine to both diets increased growth rates of

rats on both diets and eliminated the differences in growth rates of weanling rats. When the lysine content of the white bread diet was raised to that of the unsupplemented wholemeal bread diet the growth rate of rats on the white bread diet doubled, and they grew better than rats on the wholemeal bread diet unsupplemented with lysine. This last finding requires further investigation.

It is concluded that with diets adequately supplemented with vitamins and minerals the greater growth rate of weanling rats on wholemeal than on white flour is due to the slightly higher lysine content of wholemeal.—F. C. Aitken.

4880

MEREDITH, P., SAMMONS, H. G. and FRAZER, A. C. **Studies on the effects of treatment with chlorine dioxide on the properties of wheat flour. 1. The chemical composition of protein of treated flours.**

FRAZER, A. C., HICKMAN, J. R., SAMMONS, H. G. and SHARRATT, M. **2. Nutritional value of proteins of treated flours. 3. Lipid changes and vitamin content of treated flours. 4. The biological properties of untreated, normally treated and overtreated flours.** *J. Sci. Food Agric.*, 1956, **7**, 361–370 ; 371–375 ; 375–380 ; 464–470. [Dept. Pharmacol., Med. Sch., Univ. Birmingham.]

1. Flours of 78 per cent. extraction were tested chemically for the formation of abnormal substances or destruction of amino acids. A control sample was untreated ; experimental flours were treated with ClO_2 at 2 rates, the normal of 3·42 g. and tenfold of 34·2 g., and with NCl_3 65 g., also about 10 times the normal amount, each amount per 280 lb. sack. Flours were then defatted. Gluten, prepared from each by washing with tap water, was hydrolysed and examined chromatographically.

Within the limits of the nature and sensitivity of the methods employed no substance was found in the flour overtreated with ClO_2 which could be regarded as abnormal. Monochlorotyrosine was not detected in any of the treated flours. Failure to find methionine sulphoximine in the flour treated with NCl_3 was explained by its destruction during hydrolysis. Amino acid contents of the glutens with and without treatment are tabulated. Changes were in cystine, tryptophan, tyrosine, alanine and *iso*leucine but were significant probably only for the first 2, which fell by about 25 and 10 per cent., respectively.

2. In short-term experiments rats were given wheat products either untreated or treated with the normal or tenfold amount of ClO_2. In 2 trials the form was breadcrumbs, 77 or 88·5 per cent. with or without 11·5 per cent. casein, the remainder in both being yeast 7 and salt mixture 4·5 per cent. ; in the third the diet was wheat flour 86, arachis oil 9, salts 4, B vitamins 0·14 and L-lysine hydrochloride 0·86 per cent. Intake of food and gain of weight were studied for 4, 5 or 6 weeks after weaning. Statistical examination of the results indicated no difference in nutritive value between treated and untreated flours.

3. Peroxide values were estimated and effects of rancidity were assessed by feeding experiments ; vitamin E activity also was studied chemically by estimation of α-tocopherol and biologically by measurement of weight of testes in groups of rats. In untreated and normally treated flours, or bread or breadcrumbs made from them, peroxide values did not differ ; with tenfold treatment the peroxide value was high. Animals given untreated products ate more than those given treated but, relative to food consumption, increase in weight was the same with both flours. Vitamin E was destroyed both by treatment with ClO_2 and by the aeration procedure for ageing flour.

4. In long-term experiments with rats the same types of treated flours, with ClO_2 in normal and tenfold amounts, were used ; the experiments continued over 4 generations for the treated and 2 for the untreated flours. The criteria were survival rate at 55 weeks, bodyweight gained at age 100 days, fertility and number of offspring, birthweight of young and their gain in weight in the first 14 days, survival rate at weaning and weight of organs at age 15 months. The flour provided 56·8 per cent. of the diet ; other components were fishmeal 7·2, dried milk 25·6, yeast extract and dried yeast each 3·5, cod liver oil 2·8 and salt mixture 0·6 per cent. There was no difference in nutritive value between the diets with treated or overtreated and that with untreated flour.

BHARGAVA, R. P. **An experimental study on the aetiology of lathyrism.** *J. Indian Med. Assoc.*, 1956, **26**, 338–341. [S.M.S. Med. Coll., Univ. Rajputana, Jaipur.]

A pure strain of *Lathyrus sativus* seed was isolated and, for periods of 12 weeks, 8 groups of pigeons were fed on dry, soaked, or germinating and boiled seeds alone, or on a synthetic diet containing 60 per cent. lathyrus flour to which were added different aqueous or alcoholic extracts of whole seeds. Lathyrism did not appear. The birds grew on a diet of only whole dry seeds, but not if the seeds were germinating. The other groups failed to gain weight, and loss of weight occurred with germinated and boiled seeds and with soaked seeds.—D. Harvey.

4882

WALKER, D. G. and WIRTSCHAFTER, Z. T. **Resorption of embryos in rats on Lathyrus**

odoratus diet. Estrogenic inhibition of fetal resorption in lathyrism. *J. Nutrition*, 1956, **58,** 147–159; 161–173. [Res. Lab., Med. Serv., Veterans Admin. Hosp., Portland, Oreg.]

(*a*) Eighteen adult female rats were maintained from the time of conception for from 11 to 21 days on a control diet of whole wheat 67·5, casein 15, whole milk powder 10, iodised NaCl 0·75, $CaCO_3$ 1·5 and hydrogenated vegetable oil 5·25 per cent., with a concentrate of fish oil to provide vitamins A and D. Fifty-one rats were maintained on a mixture of equal parts of the control ration and seeds of the sweet pea (*Lathyrus odoratus*) for selected periods after conception. No group contained less than 4 animals. Vaginal smears were examined microscopically daily from the time of conception to the day of implantation; all the animals were X-rayed weekly throughout gestation for evidence of bone changes.

The length of time which elapsed between conception and the withdrawal of the pea diet determined the degree of resorption of the embryos. Resorption was first found in animals given the pea diet for a week or more before being killed on the eighteenth day of gestation. The embryos did not survive beyond the sixteenth day. The adult rats showed during gestation no lesion of bone or other tissue characteristic of lathyrism. Only when they were given the pea diet for at least 22 days did breeding rats develop any lesion, although in non-pregnant females lesions appeared by the fourteenth day of treatment.

(*b*) Of 20 adult female rats on the pea diet, 5 were controls and 15 were given oestrone or progesterone by injection daily from the first to the twenty-first day of gestation.

The hormones, particularly when administered in combination, protected the rat embryo against the effect of the *Lathyrus* diet.—G. F. Garton.

PYÖRÄLÄ, K., SEPPÄLÄ, T. and PUNSAR, S. Aorten- und Knochenveränderungen beim Rattenfötus verursacht durch Fütterung von Lathyrus-Samen an Muttertiere. [**Changes in the aorta and bones of the rat foetus caused by giving *Lathyrus* seeds to the mother.**] *Acta pathol. microbiol. scand.*, 1956, **38,** 273–284. [Wihuri-Forschungsinst., Helsinki.] English summary.

The diet was that of Bachhuber and Lalich (Title 2523, Vol. 25), containing 50 per cent. *Lathyrus* seeds. Four groups, in all 24 pregnant rats, received this diet at different stages of pregnancy; a group of 8 controls received the stock diet all the time. The young rats were killed and examined at birth. The females given the *Lathyrus* diet were examined also, but no pathological change was found in them.

In 9 litters from females given the *Lathyrus* diet for 15 days starting between the second and seventh day of pregnancy, all the young were born dead. They were of normal size, cyanotic, and some were slightly macerated. All had kyphosis of thoracic vertebrae, visible on inspection and by X-ray examination. The aorta was always distorted at the level of the kyphosis and abnormalities of the aortic arch were common, though the hearts were normal. Histologically the aorta was always oedematous and the elastic fibres of the media were disorganised. Dissecting aneurysms were present in several rats and haematomata in others. The thoracic vertebrae were grossly deformed, but other bones seemed to be normal.

The 5 rats which had *Lathyrus* for 6 consecutive days before the eleventh day of pregnancy had 29 young, all born alive and without abnormality. The 5 rats which had *Lathyrus* for 6 days between the eighth and sixteenth days of pregnancy had 35 young, all born alive and with normal skeleton, though one had foetal coarctation and 2 had slight abnormalities of development in the aorta. Of 34 young born to the 5 rats given *Lathyrus* during the last 8 days of pregnancy, 16 were cyanotic and dead or dying. All the young except those of 1 litter had kyphosis, all had deformed aortae, and there were 3 ruptured dissecting aneurysms, 10 not ruptured, and 9 aortic haematomata. The 6 young from a rat which had *Lathyrus* from the 17th to the 22nd day of pregnancy had no kyphosis, but the thoracic vertebrae were abnormal.

LEE, J. G., DUPUY, H. P. and ROLFS, H. E. **Dietary protein and the development of rat lathyrism.** *J. Nutrition*, 1956, **58,** 433–442. [Dept. Agric. Chem. Biochem., Louisiana State Univ., Baton Rouge.]

The growth rate and incidences of skeletal and muscular changes were studied in rats for which 1 of 3 basal diets, with 70, 70 or 60 per cent. Singletary pea (*Lathyrus pusillus*) meal and 25 or 20 per cent. dextrin or 29·5 per cent. sucrose, was provided. Additions to these diets, made at the expense of the dextrin or sucrose, were casein, whole or hydrolysed, lactalbumin, gelatine or zein or the individual essential amino acids.

Casein and lactalbumin improved gain in weight and delayed the onset of skeletal change; the effect of gelatine on weight was less than that of casein, and the effects of zein were least. Methionine was the only amino acid which was effective; it improved growth only slightly. When meal from which the toxic substance had been removed by extraction with methanol was used, both casein and methionine improved the rate of growth, the effect being greater with casein. When lathyrism was produced by including β-aminopropionitrile

with the detoxified meal, casein again delayed the incidence if the amount of nitrile was less than 0·1 per cent.

The effect of casein on the incidence of paralysis in comparison with earlier results (see Abst. 2493, Vol. 20) was to shorten the time of appearance, but in this work the animals recovered when given a stock laboratory diet.

It is suggested that the added protein overcame an interference with amino acid metabolism and that the exacerbation of paralysis resulted from the strain of more normal growth combined with a larger intake of toxin.—D. Harvey.

DASLER, W. **Protective action of glutamine, cysteine and other substances against experimental lathyrism in the rat.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 554–557. [Dept. Biochem., Chicago Med. Sch., Ill.]

Of a wide variety of supplements, only L-cysteine hydrochloride, L-glutamine, lactalbumin and casein hydrolysate partly prevented the development of skeletal deformities in rats given sweet peas or β-aminopropionitrile. For the protective action of casein and gelatine, see Abst. 5044, Vol. 24. The protection by cysteine was prolonged if the diet was made up freshly each week. The protective action of glutamine may be related to its role in the synthesis of chondroitin sulphate and mucopolysaccharide (see Boström *et al.*, *Nature*, 1955, **176,** 601; *Acta chem. scand.*, 1955, **9,** 1034).

[**Peculiar observations in the estimation of the biological quality of the proteins of edible boletus (*Boletus edulis*) and mushroom (*Psalliota bispora*) with reference to dietetics and therapeutics. Dietary liver necrosis in the rat.**] *Naturwissenschaften*, 1956, **43,** 133–134. [Inst. Gärungswiss., Univ. Cologne.]

Although rats on a mushroom diet grew poorly and most died of liver necrosis (Abst. 2073, Vol. 24), rats in 3 groups of 24 given for 4 months edible boletus, fresh, or dried free of maggots, or dried as commercially available, showed excellent growth and there was only 1 with doubtful liver necrosis. Boletus and the mushroom used were much the same in crude protein content and digestibility but differed in composition; they contained, respectively in dry matter: urea 0·18, 0·71, cystine 2·27, 0·73 and methionine 0·21, 0·52 per cent., and boletus had less proline than mushrooms. Boletus protein is considered to surpass most vegetable proteins and to be almost as good as animal protein. Other fungi are being investigated.

GOYCO, J. A. **A study of the relation between the liver protein regeneration capacity and the hepatic necrogenic activity of yeast proteins.** *J. Nutrition*, 1956, **58,** 299–308. [Dept. Biochem. Nutrit., Sch. Med., Sch. Trop. Med., Univ. Puerto Rico, San Juan.]

Groups of at least 5 male rats were given for 7 days 15 to 16 g. daily of a stock ration of vitamin-free casein 20, maize starch 50, hydrogenated vegetable oil 24, cod liver oil 2 and salt mixture 4 per cent. The rats were fasted for 48 hr. and then given for 4 days synthetic rations containing casein, dry brewer's yeast or dry *Torula utilis* yeast; the rations contained 9 or 18 per cent. protein and all were isocaloric with the stock ration. Supplementation of both yeasts with DL-methionine and torula yeast with L-cystine was also investigated, and the supplementary action of brewer's yeast on torula yeast was studied. After the 4 days the animals were killed and livers were removed for estimation of N.

Weanling rats were given to appetite rations of yeast protein 9 or 18, lard 5, salt mixture 4, cod liver oil 1 and maize starch to make 100 per cent. When animals died or at the end of 10 weeks the livers were removed for chemical analysis.

The rats which received the 18 per cent. casein ration after a fast showed 92 per cent. regeneration of liver protein; this group served as a basis for comparison of the results obtained with the rations containing yeast. The torula yeast produced liver necrosis at both the 9 and the 18 per cent. level and was incapable of restoring liver protein in the depleted animals. The brewer's yeast acted similarly at the 9 per cent. level, but at 18 per cent. it did not produce liver necrosis and was capable of restoring maximum liver protein in the depleted animals. Both DL-methionine and L-cystine at 0·5 per cent. together with the torula yeast protected all the animals from liver necrosis and also induced complete regeneration of liver protein in the depleted animals. When both yeasts were given together in the proportion of one-third brewer's and two-thirds torula yeast full protection against liver necrosis as well as optimum liver protein regeneration was obtained.

SCHIEBLICH, M. and WETZEL, I. Ist unter Verwendung von chlorbenzolsulfonsäurehaltiger Schwefelsäure hergestellte Trockenfutterhefe für Tiere unschädlich? 2. Vergleichende Fütterungsversuche an weissen Ratten mit Ratio-

nen, denen chlorbenzolsulfonsäurehaltige bzw. reine Schwefelsäure in verschiedenen Mengen zugesetzt wurde. [**Is dried fodder yeast prepared with sulphuric acid containing chlorobenzenesulphonic acid harmless for animals? 2. Comparative feeding trials with white rats with rations to which chlorobenzenesulphonic acid or pure sulphuric acid has been added in different amounts.**] *Arch. Tierernährung*, 1956, **6**, 1–34. [Vet. Physiol. Inst., Karl Marx Univ., Leipzig.]

Part 1 appeared in *Monatsh. Vet. Med.*, 1955, **10**, 515. The diet was described in that paper. Rats weighing initially about 100 g. received for 150 days the same diet with different amounts of H_2SO_4 with 25 to 30 per cent. chlorobenzenesulphonic acid, from 0·009 to 0·9 g., or of pure sulphuric acid, from 0·0082 to 0·82 g., per 50 g. diet. Each concentration was given to a group of 10 rats, and one group had no acid; each group consisted of 2 mated pairs and 6 rats kept separately.

The diets were eaten readily even with the highest proportions of acid, but the rats given the highest dose of chlorobenzenesulphonic acid ate slightly less than controls given no acid and some of the females given H_2SO_4 did not eat all their food, though this did not depend on the acid content. All the rats given the highest dose of chlorobenzenesulphonic acid survived the 150 days, but only 1 given the highest dose of H_2SO_4, 5 others dying after from 5 to 20 days. Mean daily weight gains were reduced by the 3 highest doses of chlorobenzenesulphonic acid, but the effects of H_2SO_4 on weight were irregular, and the differences were not significant with either acid.

Several pairs of rats failed to breed, but this could not be closely related to acid intake, except that 6 pairs of rats given the highest intake of H_2SO_4 all failed to breed. Of 3 pairs given the highest intake of chlorobenzenesulphonic acid 1 pair had a litter of 10, but reared none. The 2 control groups had 5 litters.

Post-mortem examination of the rats kept separately at the end of 150 days revealed a high incidence of cystitis and urolithiasis in males on the higher intakes of both acids, 4 rats in these groups with chronic gastritis and several with liver degeneration or increased interstitial tissue. These disorders, and also pyelonephritis, appeared in rats which died earlier in the experiment. No skeletal damage was revealed by X-rays.

It is concluded that rats have an extremely high tolerance of acid compared with rabbits, dogs or pigs. It is considered that H_2SO_4 containing chlorobenzenesulphonic acid is much to be preferred to pure H_2SO_4 for acidification in the production of fodder yeast.—D. Duncan.

CHRISTENSEN, F., DAM, H. and KRISTENSEN, G. **Alimentary production of gallstones in hamsters. 6. Disappearance of cholesterol stones by treatment with a non-lithogenic diet.** *Acta physiol. scand.*, 1956, **36**, 329–336. [Dept. Biochem., Polytec. Inst., Copenhagen.]

For previous parts see Absts. 4874, Vol. 23; 1033, 2406, Vol. 25.

6. Groups of 10 and 12 hamsters received for 63 and 140 days the diet which gave rise in earlier experiments to gallstones. Another 10 hamsters were fed on this diet for 63 days and then transferred to a normal diet for 77 days.

Gallstones were found in 21 out of the 22 hamsters killed at once after the experimental diet, but in only 5 of the 10 animals transferred to normal diet. The cholesterol content of the gallstones from the first 2 groups was 53 and 55 per cent., that of the gallstones from group 3 less than 0·7 per cent., indicating that the normal diet had resulted in dissolution of cholesterol.

SILBERBERG, M., JARRETT, S. F. and SILBERBERG, R. **Obesity and degenerative joint disease: experiments in "yellow" mice.** *Arch. Pathol.*, 1956, **61**, 280–288. [Snodgras Lab. Pathol., City Hosp. Div., St. Louis, Mo.]

Grey-coated and yellow-coated male and virgin female mice of the YBR/Wi strain, 345 in all, were divided into groups and, from the time of weaning until death occurred naturally or they were killed if found in poor condition, were given one of 3 diets, a stock Purina Laboratory Chow diet supplying protein 26·2 g., fat 5·4 g. and carbohydrate 48·5 g., a high-fat diet of stock diet base 75 g., lard 20 g. and lactalbumin 5 g. or a high-carbohydrate diet of stock diet base 60 g., maize starch 36 g. and lactalbumin 4 g. All the diets were allowed to appetite with water available at all times. Body-weights were recorded at weekly intervals. After

death the tibiae, femurs and, in some, vertebral columns were removed for microscopical examination.

The mice developed osteoarthritis as do mice of other strains. In yellow-coated males and females and in grey-coated females a high incidence of articular lesions was found; grey-coated males were less severely affected. The high-fat diet favoured the development of the disease in all groups except the grey-coated males. The high-carbohydrate diet had injurious effects on the joints only in yellow-coated mice. Moderate obesity had no appreciable effect on the development of osteoarthritis; excessive obesity appeared to favour its development. There were indications that neuro-endocrine or endocrine imbalances occur in the mice of this strain.—G. F. Garton.

TAKETA, F., CONSTANT, M. A., PERDUE, H. S. and PHILLIPS, P. H. **Maternal diet and resistance to dental caries in the cotton rat.** *J. Nutrition*, 1956, **58**, 519–527. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Female cotton rats in 3 groups were given a diet with 30 per cent. protein and 0·6 per cent. Ca or modifications of it with 15 per cent. protein or 0·2 or 0·1 per cent. Ca. They were mated while on these diets and their young, weaned at 17 days, were fed for 14 weeks on a high-sucrose cariogenic diet with 0·56 or 0·20 per cent. Ca (see Abst. 3499, Vol. 14). Some young rats were on their mother's diet until 6 weeks of age before being given the cariogenic diet with the lower Ca content. Rates of growth of the young were not affected by differences in the mother's diet. There was evidence that reproduction was affected when Ca in maternal diets was reduced, more especially when the protein also was low. As the Ca in the mothers' diets fell, so too did the ash content of the femurs of the young.

Data showing the higher incidence of caries when the diets of the young had the smaller Ca content, and the lower incidence which resulted from delay in introducing the cariogenic diet, confirmed earlier findings (see Constant *et al.*, Abst. 1049, Vol. 25). A change in the Ca content of the mother's diet from 0·6 to 0·2 or 0·1 per cent. had much less influence on the development of caries in the young rats' teeth than had the young rats' own diet; change in the protein content of the mother's diet had none.

Calcinosis was seen in the kidneys of some young on the diet with the lower and in the hearts of some on the diet with the higher content of Ca.

D. Harvey.

WYNN, W., HALDI, J., BENTLEY, K. D. and LAW, M. L. (with RAMSEY, D.) **Dental caries in the albino rat in relation to the chemical composition of the teeth and of the diet. 2. Variations in the Ca/P ratio of the diet induced by changing the phosphorus content.** *J. Nutrition*, 1956, **58**, 325–333. [Dept. Physiol., Div. Basic Sci. Health Serv., Emory Univ., Emory University, Ga.]

For part 1 see Abst. 2213, Vol. 26.

2. Two sets of experiments were made with the high-sucrose diet of Haldi and Wynn (Abst. 2665, Vol. 22) modified by the addition of sodium phosphate so as to give Ca : P ratios of 1 : 05, 1, 2 or 3. In one set the rats were desalivated. In the first the animals developed caries within the 70-day period; in the above order of Ca : P ratio the average caries scores were 44 ± 18, 25 ± 11, 16 ± 8 and 13 ± 8. The change with Ca : P ratio from 1 : 2 to 1 : 3 was not significant. In the second set of experiments caries did not appear within the period and estimations of N, Ca, P, Mg, F and CO_2 in enamel and dentine showed that the amounts of these in the teeth after eruption were not influenced by the Ca : P ratio of the diet.

It is concluded that the difference in the incidence of caries was not caused by a change in the chemical composition of the teeth produced by varying the Ca : P ratio in the diet.—D. Harvey.

GENERAL METABOLISM AND FEEDING HABITS OF ANIMALS OTHER THAN MAMMALS AND BIRDS

4894

WADDINGTON, C. H. and SIRLIN, J. L. **The incorporation of labelled amino-acids into amphibian embryos.** *J. Embryol. Exp. Morphol.*, 1954, **2**, 340–347. [Inst. Animal Genetics, Edinburgh.]

Axolotl and toad (*Xenopus*) embryos were allowed to develop in capsules of solution containing labelled amino acids and similar substances. Diffusion was increased by removal of vitelline membranes and cuts in blastocoel or archenteron. Incorporation of labelled substances was studied with the Geiger counter and in autoradiographs.

In *Xenopus* embryos exposed for 21 hr. to glycine-1-^{14}C the incorporation of tracer was, in descending order, epidermis, somitic mesoderm, neural tube, notochord and endoderm. In early

axolotl embryos there was preferential incorporation of glycine or of methionine-^{35}S into nuclei and possibly also into cell membranes, rather than into cytoplasm. Uptake of glycine-2-^{14}C was reduced in the presence of the antagonist *p*-fluorophenylalanine, but the inhibition was less when L-phenylalanine also was present.—D. Duncan.

4895

LALLIER, R. Chlorure de lithium et biochimie du développement de l'oeuf d'amphibien. [**Lithium chloride and biochemistry of the development of the amphibian egg.**] *J. Embryol. Exp. Morphol.*, 1954, **2**, 323–339. [Inst. Biol. Phys. Chim., Paris.] English summary.

Eggs of the frog, *Rana temporaria*, were exposed for 3 hr. at the late blastula or early gastrula stage to 4·5 parts per thousand of LiCl. Their carbohydrate metabolism was then studied by methods described.

In anaerobic conditions treated embryos consistently produced less lactic acid than normal embryos. Hexokinase and aldolase activity were not affected by lithium *in vitro*, but triose phosphate dehydrogenase was inhibited. Treated embryos had reduced consumption of oxygen, but the R.Q. was normal. Consumption of oxygen by control embryos was increased by from 30 to 74 per cent. in the presence of pyruvate, lactate, acetate, ketoglutarate, succinate, fumarate, malate or glutamate; in treated embryos oxygen consumption changed little, but it decreased in the presence of ketoglutarate or glutamate. Oxygen consumption increased in embryos treated with KCl and remained normal in embryos treated with KCl plus LiCl. In homogenates of Li-treated embryos, dehydrogenase activity was reduced but cytochrome oxidase was normal. The content of ribonucleic acid in the cell fraction containing microsomes and mitochondria was reduced after treatment of the embryos with Li. It is argued that this change in the particulate system of cells is probably fundamental for the other morphological and metabolic changes caused by Li.

MAYMONE, B., TIBERIO, M. and TRIULZI, G. A. Ricerche comparative sulla digeribilità delle foglie di gelso nelle larve di *Bombyx mori* e negli animali superiori. [**Comparative study of the digestibility of mulberry leaves for larvae of *Bombyx mori* and for higher animals.**] *Ann. Sper. agrar.*, 1956, **10**, 619–646. [Ist. Sper. Zootec., Rome.] English summary.

Samples of mulberry leaves taken between June and August for feeding silkworm larvae and sheep contained from 30·25 to 34·71 per cent. dry matter, the percentage composition of which was crude protein 20·52 to 22·34, true protein 19·93 to 20·51, crude fat 4·46 to 6·78, crude fibre 9·95 to 12·57, ash 15·86 to 17·10, and N-free extract 44·27 to 48·51. These values are compared with others from the literature. The high protein and low fibre contents are stressed.

The digestibility of the foliage was studied with fourth- and fifth-stage larvae of New White European and Green Japanese silkworms. For fourth-stage larvae of the 2 strains, respectively, percentage digestibility was dry matter 76·06 and 85·35, organic matter 73·76 and 84·70, true protein 89 and 93·13, crude fat 95·45 and 97·44, fibre 48·63 and 68·10, N-free extract 71·77 and 83·76, and lignin 57·97 and 77·01. Corresponding values for fifth-stage larvae were 58·69 and 47·66, 58·54 and 46·52, 86·76 and 83·63, 84·87 and 79·96, 24·24 and —, 51·77 and 36·10, and 30·50 and 28·42. For 3 sheep the mean values were for dry matter 70·30, organic matter 75·54, true protein 87·89, crude fat 43·85, fibre 55·53, N-free extract 81·68 and lignin 14·15. The value by the Kellner system was 93 Scandinavian feed units per 100 kg. dry matter for fourth-stage larvae, 59 for fifth-stage larvae and 90 for sheep, with 18, 17 and 17 per cent. digestible protein.—D. Duncan.

4898

LEA, A. O., DIMOND, J. B. and DELONG, D. M. **Role of diet in egg development by mosquitoes (*Aedes aegypti*).** *Science*, 1956, **123**, 890–891. [Dept. Zool. Entomol., Ohio State Univ., Columbus.]

Groups of 200 fertile female mosquitoes were fed for 16 days on different solutions in saturated cotton pads. Daily counts were made of eggs laid. In descending order of value, based on the number of eggs, were citrated beef blood, egg albumin, enzymic digest of casein, fresh skimmed milk, proteose-peptone, enzymic digest of lactalbumin, enzymic digest of yeast and digest of soya bean meal, all with 10 per cent. honey.

A medium containing 18 amino acids, dextrose, fructose and a salt mixture allowed females to produce viable eggs; so did a mixture with 12 amino acids. Eggs were not deposited in the

absence of arginine, *iso*leucine, leucine, lysine, phenylalanine, threonine, tryptophan or valine and few were deposited in the absence of histidine, methionine, cystine or glutamic acid. The best results were obtained when all 12 were present. Optimum amounts of each were found.

D. Duncan.

McGinnis, A. J., Newburgh, R. W. and Cheldelin, V. H. **Nutritional studies on the blowfly, *Phormia regina* (Meig.).** *J. Nutrition*, 1956, **58,** 309–323. [Dept. Chem., Oregon State Coll., Corvallis.]

Flies were reared on a diet containing, per cent., vitamin-free casein 26, yeast extract 3, agar 1 and water 70, with, in mg. per 100 g., cholesterol 0·78, NaCl 0·7, KCl 0·015, $CaCl_2$ 0·015, $NaHCO_3$ 0·015, $NaH_2PO_4 . H_2O$ 0·41 and K_2HPO_4 0·35. The adults were kept on sucrose cubes and water, but when they were desired to lay eggs fresh liver or kidney was given.

Nine experimental diets were used, with different proportions of casein or its hydrolysate, glucose, sucrose, starch and DL-tryptophan. The standard had 29 per cent. casein. In another experiment a mixture of 18 amino acids was substituted for casein and individual amino acids could be omitted.

With 6 per cent. glucose replacing casein, growth was retarded by about 15 per cent., and with 10 per cent. glucose larval mortality was high. Sucrose at 6 per cent. allowed better growth than glucose, and starch was similar. Starch was the only carbohydrate tested which allowed growth at the 10 per cent. level. Casein hydrolysed either with acid or with enzymes gave poor results, and addition of the diet with enzymic hydrolysate to the standard diet caused inhibition of growth. Of individual amino acids added to the standard diet, D-serine was toxic, but its effect could be prevented by excess of D-alanine. It was not thought to be concerned in the effect of casein hydrolysates, since these should contain only L-amino acids.

A chemically defined medium was evolved on which pupation was 4 days later than on the standard diet, but which gave good growth. It contained, in mg. per ml., DL-alanine 2·58, L-arginine 1·06, DL-aspartic acid 3·06, L-cystine 0·36, L-glutamic acid 5·48, glycine 0·70, L-histidine 0·70, hydroxy-L-proline 0·48, DL-*iso*leucine 3·06, L-leucine 2·80, L-lysine 1·76, DL-methionine 1·88, DL-phenylalanine 2·80, L-proline 2·00, DL-threonine 1·88, DL-tryptophan 0·94, L-tyrosine 1·64, DL-valine 3·30, ribonucleic acid 1·0, cholesterol 1·0, inorganic salts 2·4 and agar 25·0, and in μg. per ml., vitamin B_1 5, riboflavin 15, pyridoxine 15, inositol 100, nicotinic acid 15, choline chloride 100, Ca pantothenate 15, *p*-aminobenzoic acid 15, folic acid 5 and biotin 0·025. The 10 essential amino acids were arginine, histidine, *iso*leucine, leucine, lysine, phenylalanine, proline, threonine, tryptophan and valine. The N content of the chemically defined diet was only a tenth of that of the casein diet, but when the concentration of amino acids was more than 60 mg. per ml. growth was inhibited. A high osmotic pressure may be harmful to the larvae. Of the vitamins, *p*-aminobenzoic acid and inositol were not required; in absence of folic acid and biotin pupation occurred but the flies failed to emerge. The other 6 vitamins were essential. Reproduction was not studied with this diet.—D. Duncan.

VOORLICHTINGSBUREAU VAN DE VOEDINGSRAAD. Aanbevolen hoeveelheden voedingsstoffen per dag. [**Recommended amounts of nutrients per day.**] *Voeding*, 1956, **17**, 202–204. [Koninginnegracht 42, The Hague.]

A table gives mean requirements for the same nutrients as specified in 1952 (see Abst. 3390, Vol. 23) but for different age groups. Amounts are specified for children in 5 age groups up to 12 years, for boys and girls separately at ages 13 to 15 and 16 to 19 years and for men and women separately at ages 20 to 29, 30 to 44, 45 to 64 and 65 years and over. The adult requirements are further subdivided according to, for men, 4, 4, 3 and 2 and, for women, 3, 3, 3 and 2 grades of work at these respective ages. The standard of weight is 70 kg. for a man and 60 kg. for a woman.

LEVERTON, R. M., JOHNSON, N., PAZUR, J. and ELLISON, J. **The quantitative amino acid requirements of young women. 3. Tryptophan.** *J. Nutrition*, 1956, **58**, 219–229. [Nebraska Agric. Exp. Stat., Lincoln.]

3. Tryptophan was the third of the amino acids studied; for other parts see Absts. 3538, 4685, Vol. 26. Eight college girls were the subjects, and auxiliary foods supplied, on the average, 7 mg. tryptophan daily. With 307 mg. N balances for all were positive and with 82 mg. negative. With 120 mg. 3 of the 8 were in negative balance and of 5 given 157 mg. all were in positive balance. When all were tested with a mixture which supplied 157 mg. tryptophan and adequate amounts of threonine, valine, phenylalanine and leucine, N balance was positive in all.

The rounded amount of 160 mg. is taken to be the minimum daily requirement for tryptophan of young women like these.—D. Harvey.

4906

SWENDSEID, M. E., WILLIAMS, I. and DUNN, M. S. **Amino acid requirements of young women based on nitrogen balance data. 1. The sulfur-containing amino acids.**

SWENDSEID, M. E. and DUNN, M. S. **2. Studies on isoleucine and on minimum amounts of the eight essential amino acids fed simultaneously.** *J. Nutrition*, 1956, **58**, 495–505; 507–517. [Dept. Home Econ., Univ. California, Los Angeles.]

1. Eight women between 21 and 30 years of age were given a semi-synthetic diet with from 7 to 8 g. N daily, in which peanut protein, L-isomers of essential amino acids and glycine were the main sources of N; only small amounts, from 0·3 to 0·4 g., were derived from the natural foods in the diet. In its complete form the diet supplied 1000 mg. sulphur amino acids, 200 mg. as cystine and 800 mg. as methionine; on it all 8 subjects were in N equilibrium. When methionine was removed from the amino acid mixture, so that intake of methionine was reduced to 150 mg., giving a total of 350 mg. sulphur amino acids, 5 subjects remained in equilibrium. Methionine was then added in 100-mg. amounts to the diets of the 3 other women; one such increment was sufficient to bring 2 of them into equilibrium but the third required two.

2. Seven women between 20 and 36 years of age were the subjects in a similar investigation. The complete diet supplied from 6 to 7 g. N daily and 1330 mg. *iso*leucine, 1280 mg. from the mixture and 50 mg. from the natural foods. At that level all were in N equilibrium. When *iso*leucine was removed from the mixture and the intake of it was only 50 mg., all were in negative N balance, lost N at the rate of about 1 g. daily, and experienced extreme discomfort. The amino acid was then restored in amounts of 100 mg. With one increment results were indefinite; with two, 4 of the subjects were not in equilibrium but 3 of these were so after 3 increments; the fourth subject required 4 increments.

The findings in both studies are discussed in relation to those of other workers.—D. Harvey.

JELLIFFE, D. B. **Breast feeding in technically developing regions (with especial reference to West Bengal).** *Courrier*, 1956, **6,** 191–195. [Dept. Paediat., All India Inst. Hyg. Pub. Health, 110 Chittaranjan Ave., Calcutta.] French and Spanish summaries.

The incidence of breast feeding at 6 months was 100 per cent. in a small group of rural women and 95 per cent. in one of urban women, both of lower socio-economic status in West Bengal. In a group of women of higher economic status in Calcutta the percentage was 46. The decline of breast feeding in the upper socio-economic groups of developing countries is in line with that in Western countries. In developing countries educational measures are needed to prevent the middle and lower socio-economic groups from following the same path.—F. C. Aitken.

4910

SALBER, E. J. **The incidence of breast feeding on discharge from hospital of European, Coloured, Bantu and Indian infants.** *S. African Med. J.*, 1956, **30,** 339–344. [Dept. Med., Univ. Cape Town.]

The percentage incidence of breast feeding was for Bantu 98·6, Coloured 97·9, European 93·4 and Indian 71·1. In all except the Coloured multiparae were more successful than primiparae. The effect of age of mother and rank of baby was studied in European and Indian mothers. Of Europeans the most successful were mothers of 20 to 29 years having babies of rank 5. The most successful Indian group was that of the youngest mothers having their first babies. The most unsuccessful Indian group was that of the youngest mothers having their second to fourth babies. Milk came into the breasts sooner in Bantu than in Indian and in both groups sooner in multiparae than in primiparae.—F. C. Aitken.

MILLIS, J. **The influence of breast feeding on weight gain in infants in the first year.** *J. Pediat.*, 1956, **48,** 770–775. [Dept. Social Med. Pub. Health, Univ. Malaya, Singapore.]

This study is based on 60 male and 54 female infants from Chinese families in middle and upper income groups in Singapore in 1953; 59 infants were breast fed for less than 12 weeks and 30 for over 24 weeks. For these groups mean weight in oz. at 4-week intervals is tabulated along with those for infants from poor Indian families (Abst. 2634, Vol. 25) and poor Chinese families (Abst. 3582, Vol. 26) [date in reference should be 1954, not 1953].

Analysis of variance showed that at 1 year of age the boys, but not the girls, of the first group were significantly heavier than those breast fed for over 24 weeks. In contrast to findings for infants from poor Indian and poor Chinese families, infants fed in different ways did not differ significantly in weight at 24 weeks. The deviations from the earlier results are attributed to the better artificial feeding and hygiene in the better-off families.—W. M. Deans.

4912

HENDERSON, J. L. **Feeding problems in infants.** *Practitioner*, 1956, **176,** 378–385. [Dept. Child Health, Univ. St. Andrews.]

A brief account is given of the general principles of infant feeding, the management of breast and artificial feeding, the introduction of mixed feeding and the avoidance of feeding problems. When national dried milk is used, half-cream milk is advocated for young infants, with gradual introduction of full-cream milk at from 6 to 12 weeks, according to progress and appetite. It is considered that there is no justification for beginning mixed feeding before the age of from 4 to 5 months.

F. C. Aitken.

4913

BERGER, H., WAVRE, D. and GILARDI, A. Die Ernährung von reifen Säuglingen und Frühgeburten mit HUMANA-Milch. Eine klinische Untersuchung. [**Feeding mature and premature infants with HUMANA milk. Clinical study.**] *Ann. paediat.*, 1956, **186,** 383–406. [Kinderklin., Univ. Basle.] English and French summaries.

A clinical trial is reported in which pooled human milk was partly or wholly replaced by buttermilk, lactic acid milk, or Humana milk, a preparation of cow's milk modified to resemble human milk (see Lemke, Abst. 1069, Vol. 22), over periods of 2 or 3 weeks. In all there were 134 mature infants, and 92 premature (these did not have lactic acid milk), all treated at different

times in the same hospital ward. The compositions of the diets are given. According to the Swiss manufacturer (Schweizerische Milch-Gesellschaft A.G., Hochdorf, Lucerne), Humana milk as given supplies, per 100 ml., 67 Cal., Fe 0·4 mg., vitamin C about 3·5 mg. and vitamin D 200 I.U. There were 5 or 6 feeds daily, in amount regulated by the rate of gain of weight. The results are tabulated.

For mature infants, in mixtures with human milk, Humana milk gave a mean daily weight gain intermediate between those for buttermilk (highest) and lactic acid milk. Alone, lactic acid milk was best and Humana not quite so good as buttermilk. Differences in energy quotient [not defined] were trifling.

For premature infants, Humana milk alone or with human milk gave weight gains which were satisfactory but not quite so good as those with buttermilk alone or mixed.

Results were also good in 21 infants, including 9 premature, examined after they went home, except for 4 which were overfed, generally because the mother thickened the feed with gruel.

In the hospital infants given Humana milk, appetite was generally good. Their stools tended to resemble those of breast-fed infants in colour, consistency and odour; bacteriological findings will be published elsewhere. Infections were few.

X-rays of the wrist of 86 premature infants, some of whom had the usual massive treatment with vitamin D, and of 28 mature infants in whom there was clinical suspicion of rickets, at intervals during a year, indicated that although Humana milk did not contain enough vitamin D to prevent rickets in all, signs of healing were more frequent than in those given buttermilk or human milk. No ill effect of the added vitamin D was seen.—W. M. Deans.

WALCH, E. Zur Frage der Beeinflussbarkeit der Darmflora des Säuglings durch N-Acetyl-D-glucosamin-derivate. [**Effect of derivatives of N-acetyl-D-glucosamine on the intestinal flora of infants.**] *Deutsch. med. Wochenschr.*, 1956, **81**, 661–664. [Frauenklin., Univ. Heidelberg.]

The substance studied was synthetic β-ethyl-N-acetyl-D-glucosaminide, referred to as N 180. It was given to 35 newborn infants artificially fed on a mixture of half cow's milk and half 6 per cent. oat gruel, with 5 per cent. sucrose. Each received 50 mg. N 180 per 100 g. food, and the faecal flora were compared with those of 50 infants on the same regimen without N 180, or breast fed.

The stools of infants given N 180 were similar in colour and consistency to those of breast-fed infants, with a *p*H between 5·0 and 6·5. The flora was almost exclusively Gram-positive, with about 65 per cent. *Lactobacillus bifidus*. In 5 infants fed on the half cow's milk diet and not given N 180 until they were some days old the proportion of *L. bifidus* in the faecal flora, at first low, increased considerably within 24 to 48 hr. after N 180 was introduced. When N 180 was added to Humana milk for 12 infants, the faecal flora became indistinguishable from that of breast-fed infants, with up to 90 per cent. *L. bifidus*.

EPPRIGHT, E. S., JEBE, E., SIDWELL, V. D., MARLATT, A. L., NORTHAM, J. I., BISCHOFF, G. A., CLARK, R. M., MCGRATH, B. C., LOOSE, B. L., CELLUCCI, H. W., PATTON, M. B., GLUYAS, S. B., TYRRELL, D., BASNETT, D. T., GLENN, G., ADRIAN, F., BOWSER, M. and ANDERSON, B. **Nutrition of 9-, 10- and 11-year-old public school children in Iowa, Kansas and Ohio. 1. Dietary findings.** *Iowa Agric. Exp. Stat. Res. Bull.* No. 434, December 1955, pp. 18.

1. The nutritive value of the diets of 1700 children was assessed from 3-day diet records kept by the children in 1948–51. Except for Ca, the

average intakes of boys and girls for each year of age and each state conformed to or exceeded the U.S. National Research Council's recommended allowances (1953). Only 10, 21 and 25 per cent. of the boys and 8, 9 and 13 per cent. of the girls in Kansas, Ohio and Iowa, respectively, had diets which conformed fully to the recommendations. Children who had school lunches tended to have nutrient intakes better than those who did not.

HARD, M. M. and ESSELBAUGH, N. C. **Nutritional status of selected adolescent children. 1. Description of subjects and dietary findings.** *Amer. J. Clin. Nutrition*, 1956, **4**, 261–268. Washington Agric. Exp. Stat., Pullman.]

1. Two areas in Washington State, Snohomish County and Yakima County, were chosen for study for the reasons that incidences of dental caries differed, the F content of the drinking water in both was below the level currently recommended for the control of caries, their climates were widely different and the population was non-migratory. The children studied were aged 15 and 16 years.

Seven-day diet records were obtained in Snohomish County from 63 boys and 62 girls and in Yakima County from 61 boys and 62 girls. Each recorded his or her own food.

In Snohomish County the boys had a significantly higher intake of Ca and the girls of ascorbic acid compared with boys and girls in Yakima County. Differences between the areas in intakes of other nutrients were not significant. In general the diets of girls were poorer than those of boys, especially in Fe, Ca and ascorbic acid. Both boys and girls had less ascorbic acid than the amount recommended by the U.S. National Research Council. Interpretation of nutrient intake and medical and biochemical findings will be discussed in subsequent reports.

Summarised data on heights and weights, Wetzel grid ratings, urine constituents and Hb values are reported. According to the Baldwin and Wood standards the boys tended to be taller than average for their age. A higher percentage of girls than of boys were overweight. About one-fifth of the girls were overweight by 10 per cent. or more. In Snohomish and Yakima Counties, respectively, average Hb values were for boys 14·6 g. and 15·0 g., and for girls 13·6 g. and 13·3 g. per 100 ml.—F. C. Aitken.

CHALMERS, F. W., CHAPMAN, L. L., LAWLESS, J. J., LEWIS, W. R., STREGEVSKY, S., VOTH, O. L. and VANLANDINGHAM, A. H. **Nutritional status studies in Monongalia County, West Virginia.** *W. Virginia Univ. Agric. Exp. Stat. Bull.* No. 375T, June 1955, pp. 31.

Diet studies with clinical observations were made on 3 occasions in West Virginia. In 1950–52 the subjects were 430 schoolchildren aged from 7 to 12 years, of whom 46 per cent. were in urban, 44 in industrial or mining and 10 per cent. in rural areas; in 1952–53 they were 462 schoolchildren from 7 to 15 years of age in 4 small coal-mining communities; from this last group the studies were extended to include social conditions and blood composition for other members of the families, and 39 families with 57 adults and 137 children participated in this survey. The diet studies were by the 24-hr. recall method; the blood analyses were by methods already described (Abst. 140, Vol. 22). The results are summarised in 15 tables in which nutrient intakes are compared with U.S. National Research Council recommendations (1948) and blood constituents are grouped in categories poor, fair, good or excellent by the system of Bessey and Lowry quoted from *Final Report New York Joint Legislative Commission on Nutrition*, 1947, pp. 167–192.

In the first study intakes of Ca and P were below recommended amounts for, respectively, one-half and one-third of the population; about a fifth were receiving less than half the amount of ascorbic acid; vitamins of the B group were often smaller than, but seldom fell below two-thirds of, the amounts suggested. In blood, the level of vitamin A was poor for a quarter of the children and that of ascorbic acid poor or fair for 38 per cent. The commonest of 14 clinical states were gingivitis, cheilosis and thyroid enlargement. In the second study dietary and clinical data were similar with, in addition, the possibility that intakes of protein, Fe and riboflavin also were low. In the third study, in which families of children known to be undernourished were selected, more than half of the children were rated poor or fair for ascorbic acid in blood, and its level was low in the blood of the parents as well. The children were frequently underweight by the standards of Baldwin and Wood; adult women were often overweight.

The findings are discussed in comparison with other North-eastern surveys (see Absts. 3430, Vol. 23 and 2265, 2266, Vol. 24).—D. Harvey.

4921

CERVIÁ, T. Los valores hematológicos medios en Canarias. (Nota previa.) [**Mean haematological values in inhabitants of the Canary Islands. Preliminary note.**] *Rev. clín. española*, 1956, **61**, 39–40. [Inst. Fisiol. Regionales, Tenerife.] English, German and French summaries.

The blood picture of inhabitants of the Canary Islands frequently shows red cell counts between 3·5 and 4 million per c.mm., leucopenia and neutro-

penia, associated with achylia, vascular fragility and vague and poorly localised pain. The syndrome is especially common in women who have immigrated from the mainland. The diet is monotonous, with much carbohydrate and relatively little protein, lacking fresh foods and fruit and rich in K. The uncertain supply of vitamins may be unbalanced by "abuse of some synthetic vitamin preparations". The condition is to be studied more fully in relation to the diet.

REVERTE, J. M. and PEREZ, C. Estudios clínicos nutricionales en poblaciones de Panamá. 1. La Mesa, Provincia de Veraguas. [**Clinical and nutritional studies of the inhabitants of Panama. 1. La Mesa, Province of Veraguas.**]

PEREZ, C. and PEDRESCHI, C. 2. Barrio El Chorrillo, ciudad de Panama. [**2. Barrio El Chorrillo, city of Panama.**] *Bol. Ofic. sanit. panamer.*, 1955, Suppl. No. 2, 27–32; 33–37. [Dept. Salud Púb., Panamá.]

1. La Mesa has a semi-rural population of 591, almost isolated from other populations; about half live in a village, the rest on scattered farms. Fifty children of both sexes, aged from 7 to 10 years and of low social and economic status, were selected for clinical examination.

The 6 children of 7 years were on the average 5 kg. and 9 cm. below the weight and height standards of the Institute of Nutrition of Central America (1952), and the two 10-year-olds were 7 kg. and 11·7 cm. below. The incidence of clinical signs of malnutrition, which are tabulated, was high, especially that of conjunctival pigmentation and vascularisation. Ten children had diffuse goitre of grade 1. The 38 samples of serum examined showed normal values for protein, vitamin C and riboflavin, and low values for vitamin A and carotene. Alkaline phosphatase levels were high, but there was no rickets. In 37 of 39 blood samples there was macrocytic anaemia. Of 42 samples of faeces, 33 contained *Necator americanus*, 29 *Ascaris lumbricoides*, 18 *Trichuris trichiura* and 4 *Strongyloides stercoralis*, either as worms or eggs, and some contained also *Entamoeba* and *Giardia* spp.

2. The subjects, from a suburban district of the city of Panama, were of low economic class and of mixed race. They were 79 boys and 71 girls, 68 of them up to 5 years old and the rest between 7 and 10. The examination was similar to that described above.

The infants up to a year old were not much below normal in height and weight for age, but between the second and fifth years there was a severe setback and this was not made up by the tenth year. The clinical state was better in the pre-school children than in those of school age. The commonest clinical findings were vascularisation and pigmentation of the bulbar conjunctiva and bad teeth. Serum analyses showed low levels of protein in many in the pre-school group and of vitamin A and carotene at all ages. Of 116 blood samples 79 indicated anaemia, which in 73 was macrocytic; all the samples from school children showed macrocytic anaemia. Half the faecal samples contained parasites, especially *Entamoeba coli* and *Trichuris trichiura*.

D. Duncan.

4923

SOGANDARES, L. and DE BARRIOS, G. Estudios dietéticos en Panamá. 1. La Mesa, Provincia de Veraguas. [**Dietary studies in Panama. 1. La Mesa, Province of Veraguas.**]

SOGANDARES, L. (with DE BARRIOS, G. and DE CORCO, E. Z.) 2. Barrio El Chorrillo, ciudad de Panamá. [**2. Barrio El Chorrillo, city of Panama.**] *Bol. Ofic. sanit. panamer.*, 1955, Suppl. No. 2, 38–46; 47–53. [Sec. Nutrición, Dept. Salud Púb., Panamá.]

1. The dietary study in La Mesa (see preceding Abst.) embraced 24 families with 151 members in March 1952, and 14 of these families with 96 members in November 1953. Daily visits were made to each house for 7 successive days.

The mean daily intake of each type of food per person per week is tabulated. The staple food was rice. The preparation of food is described. The mean intakes per head at the 2 inquiries were 1927 and 1958 Cal., 55 and 54 g. protein with 37 and 34 per cent. from animal sources. Half the families had an adequate intake of protein, but fewer had enough animal protein. Intakes of Fe and nicotinic acid were good, those of vitamin B_1 and vitamin C almost adequate, and those of Ca, vitamin A and riboflavin low.

2. The dietary study in El Chorrillo was made in March and April 1954. The 13 families were chosen from those of the children examined clinically (see preceding Abst.), and their heads ranged from expert artisans to unskilled labourers; the heads of 2 families were women, of whom one depended mainly on public assistance and the other on the earnings of adolescent sons. The mean income of 10 of the families, with a mean of 7 members each, was 78·00 Balboas monthly (B); 1 B equals 1 U.S. dollar. The mean expenditure on food was about B 1·63 weekly per person. The 13 families had a total of 88 permanent members.

The staple food was rice, with a mean intake of 180·8 g. per head daily. The intake of meat, on the average 86·8 g. daily, was much greater than that of the rural population. The mean intake of energy was 1454 Cal. per person daily and that of protein 44 g., half of animal origin. The energy

intake was thus only 86 per cent. of the allowance recommended by the Institute of Nutrition of Central America (1952) and the protein intake 89 per cent. Intakes of Fe and nicotinic acid were adequate ; those of Ca, vitamin A and riboflavin were especially low. The energy intake was adequate in about 75 per cent. of the families, that of protein in 62 per cent.—D. Duncan.

4924

PEREZ, C., ARCE PAIZ, A. and MAZA, E Estudios clínicos nutricionales en poblaciones de El Salvador. 1. Cantón Platanillos, Municipio de Quezaltepeque, Departamento de La Libertad. [**Clinical and nutritional studies of the inhabitants of El Salvador. 1. Platanillos Canton, Municipality of Quezaltepeque, Department of La Libertad.**] *Bol. Ofic. sanit. panamer.*, 1955, Suppl. No. 2, 22–26. [Inst. Nutrición Centro Amér. y Panamá, Guatemala.]

1. Platanillos is a poor agricultural community situated in an arid district 3 km. from the town of Quezaltepeque. A group of 305 persons formed the subject of clinical study, and of these 148 were included in the diet survey (see next Abst.) ; 94 were less than 7 years old, 94 were from 8 to 18 years and 117 were 19 or more. Height, weight, clinical state, thickness of subcutaneous tissue and Hb were recorded for all subjects and samples of faeces and blood from some were examined.

The exact chronological age was known in only 45 of the pre-school children ; by comparison with the standards of growth of the Institute of Nutrition of Central America (1952), the boys were 30 to 40 per cent. below normal weight and 20 to 40 per cent. below normal height for age ; for girls corresponding values were 40 to 60 and 30 to 40 per cent. In all the groups the incidence of clinical findings associated with malnutrition was high, and 57 cases of goitre were found ; 40 per cent. of the children were considered to be in a poor state of nutrition.

In 56 samples of serum, mostly from subjects less than 20 years old, carotene was extremely low. Of 51 subjects with low Hb, 45 per cent. had macrocytic and 47 per cent. hypochromic anaemia. Of 42 samples of faeces, 29 contained parasites or their eggs, most commonly *Necator americanus*, *Ascaris lumbricoides*, *Trichuris trichiura* and *Hymenolepis nana*.—D. Duncan.

4925

CASTILLO, A. S. and FLORES, M. Estudios dietéticos en El Salvador. 2. Cantón Platanillos, Municipio de Quezaltepeque, Departamento de La Libertad. [**Dietary studies in El Salvador. 2. Platanillos Canton, Municipality of Quezaltepeque, Department of La Libertad.**] *Bol. Ofic. sanit. panamer.*, 1955, Suppl. No. 2, 54–65. [Direccion Gen. Sanidad, El Salvador.]

2. Platanillos (see preceding Abst.) has a total population of 1084 in 180 houses. The index of births in the 5 years up to 1952 was 44·3 per cent. [*sic*] and mortality 1·76 per cent., with infantile mortality 131·2 per 1000 live births. The main causes of infant mortality were diarrhoea and enteritis, respiratory disorders, infections and malnutrition.

The water supply for human and animal needs comes from streams, but one well supplies a limited number of families. Some 95 per cent. of the houses lack latrines.

Most of the people were born in the district. About 45 per cent. of the adults can read and write and 52 per cent. of the children between 6 and 15 years go to school ; the girls usually leave at 10 or 12. The women spend much of the day in making cloth and the men in farming ; the main crops are maize, beans, sorghum, sugar cane, yucca and rice. During the dry season the people work in the sugar factories. A few families have cows.

The subjects of study were 264 persons in 43 families during the dry season and 106 persons in 15 families during the wet season. For the diet survey each house was visited once or twice daily for 7 days. Most of the food was weighed.

The quantities of foods eaten are tabulated in g. per person per week. The staple food was maize. In the dry and wet seasons, respectively, meat was eaten, on the average, 4 and 3 times a week, milk once and 5 times, cheese twice and 5 times, eggs twice and once. The mean intakes were energy 2267 and 2131 Cal., protein 58 and 62 g., animal protein 8 and 11 g., daily. Fe intake was high and intakes of vitamin B_1 and nicotinic acid were adequate ; intake of vitamin A was only 770 and 640 I.U. and that of riboflavin also was low ; vitamin C intake was adequate or high in the wet season when there was plenty of fruit.

The people are co-operative and would benefit from education in the improvement of the diet.

D. Duncan.

4926

REH, E. and FERNANDEZ, C. Condiciones de vida y de alimentación en cuatro grupos de población de la zona central de Costa Rica. [**Living conditions and diet of four groups of the population of the central zone of Costa Rica.**] *Bol. Ofic. sanit. panamer.*, 1955, Suppl. No. 2, 66–89. [Inst. Nutrición Centro Amér. y Panamá, Guatemala.]

The 4 groups studied live in the central plateau of Costa Rica, about 1150 metres (3770 ft.) above sea level. The mean annual temperature is about 20° C. and the annual rainfall 1850 mm. The investigation was made in the second half of the

rainy season when supplies of some foods were best. The 4 districts were a middle-class part of the town of San José, Lourdes, a suburb of San José, the rural village of Villa Colón, and the country district of Ticufres-Quitirrisi. For the medical and laboratory study a group of schoolchildren under 10 years was chosen in each district, 75 from the first and 25 from each of the others. Of these 150 children 51 were included in the diet survey. There were, in their families, totals of 177, 48, 79 and 60 persons in the respective districts, and mean family sizes were 6·8, 6·9, 8·0 and 8·6 persons. The method of selection automatically eliminated families whose children did not go to school and whose status was probably lowest. The proportion of subjects below 14 years was high and over 50 years low. Housing conditions and family occupations are tabulated. For the diet survey the houses were visited 4 times on alternate days, half one day and half the next, except in the rural districts where they were visited daily.

The weekly amounts of food are tabulated for each group. The weekly cost in colones (8·89 colones = 1 U.S. dollar) was 9·59, 8·02, 5·95 and 4·78 per head in the 4 areas. The proportion of food grown at home was 2, 4, 20 and 28 per cent. In an analysis of the nutritive value of the diets each population group was divided into the " poor " and others. The village poor had the lowest energy intake, 1559 Cal. per head daily, and the suburban better-off people the highest, 2404 Cal. Total protein ranged from 39 to 62 g. daily, with much the same distribution, and animal protein from 3 in the rural group to 24 g. in the urban group. The town and suburban groups also had the highest intakes of Ca, vitamin A and riboflavin. The proportions of the recommended allowances eaten by each group are tabulated.

The schoolchildren in all the areas were below U.S. standards in height, weight and skeletal maturation by about 2 years. Clinical signs of malnutrition were rare. There was some goitre in San José. The incidence of dental caries was high everywhere. Anaemia was not prevalent. Faeces examinations showed only 6 per cent. of the children free from parasites. In serum, protein and riboflavin were normal, ascorbic acid high and vitamin A and carotene very low. Suggestions were made for improving the diet, and especially the school meals.—D. Duncan.

FLORES, M. and REH, E. Estudios de hábitos dietéticos en poblaciones de Guatemala. [**Dietary habits of the inhabitants of Guatemala.**] 1. Magdalena Milpas Atlas. [**1. Magdalena Milpas Atlas.**] 2. Santo Domingo Xenacoj. [**2. Santo Domingo Xenacoj.**] 3. San Antonio Aguas Calientes y su aldea, San Andrés Ceballos. [**3. San Antonio Aguas Calientes and the nearby village, San Andrés Ceballos.**] 4. Santa María Cauqué. [**4. Santa María Cauqué.**] *Bol. Ofic. sanit. panamer.*, 1955, Suppl. No. 2, 90–128 ; 129–148 ; 149–162 ; 163–173. [Inst. Nutrición Centro Amér. y Panamá, Guatemala.]

1. Magdalena Milpas Atlas is the capital of the Department of Sacatepéquez, on a hill with a deep valley on each side. The town is 2062 m. (6765 ft.) above sea level and has a mean annual temperature of 16·6° C. It has much wind, especially in the dry season. The rainy season is from May to October. Shortage of water is a serious problem, as there is no river near and the springs are the only places for washing. The region depends much on maize growing and produces a surplus for sale.

Magdalena has 291 families, of which 22 were included in the dietary survey and 206 in the economic study. The total population in 1952 was 1092. The birth rate was 28 and the mortality 21 per 1000. The death rate in the first year of life was 28 per cent. ; mortality in children from 1 to 4 years old also was high. Health is reviewed.

The families of 22 schoolchildren between 7 and 11 years old were studied. For the diet survey each house was visited daily for a week. There was one well-to-do negro (" ladino ") family of 10 members, and of the 21 native families 6 were classed as well-to-do, 10 as medium and 5 as poor ; the mean sizes of the families were 5·4, 6·7 and 5·5 persons. The quantities and types of food consumed are given in detail. The poor group ate most cereals, 40 per cent. of the total diet, and least animal products, 19 per cent. On the standards recommended by the U.S. National Research Council all the groups had enough energy, protein, Ca, Fe, vitamin B_1 and nicotinic acid, some had enough vitamin C, but vitamin A and riboflavin were deficient.

2. Santo Domingo Xenacoj is a town in the Department of Sacatapéquez, 2064 m. (6771 ft.) above sea level, with a mean annual temperature of 15·6° C. and very cold weather from November to February. The rainy season is from May to October. Besides agriculture there are 2 industries ; the women weave and the men make charcoal. One of the main difficulties is lack of water.

There were 1875 inhabitants by the 1950 census, 1694 natives and 181 negroes. Most are illiterate. The birth rate is 55 and the death rate 40 per 1000, with mortality of 31 per cent. in the first year of life. Data about health are inadequate because of lack of medical services. Of 59 samples of faeces from schoolchildren only 12 showed no parasites and four-fifths had *Ascaris lumbricoides*.

Neither houses nor clothes give sufficient protection from the climate.

From the school registers 50 children from 7 to 10 years old were selected and of these the families of 27 were visited. Finally 23 families took part in a diet study. Four families were negroes, and the 19 native families were classed as poor and very poor. The quantity of food eaten by each family in a week is tabulated. Maize is the staple food.

The energy intake did not differ much from the recommended allowances of the U.S. National Research Council, but amounts of animal protein were low, from 5 to 15 g. daily. Intakes of Ca, Fe, vitamin B_1 and nicotinic acid were adequate and the native families had enough vitamin A and vitamin C, but the negroes had not. Riboflavin intakes were consistently low and no family had enough. On the whole the very poor families had a slightly better diet than the poor.

3. The 2 settlements lie in an isolated valley 1445 metres (4740 ft.) above sea level, with a mean annual temperature of 18·8° C. The soil is excessively wet all the year round and contains much volcanic ash. All the men in San Andrés are engaged in agriculture and, except for the small tradesmen and craftsmen, so are most of those in San Antonio. The standard of housing is much higher in San Antonio. The whole district has a population of 2637, including 350 in the village of San Andrés and probably also the inhabitants of another village not studied. Nearly all are of native origin and 57 per cent. of persons aged 7 years or more are illiterate ; there are 226 schoolchildren. From the public school and a mission school were selected 20 children, half living in each centre of population, and the diet survey was made on their families. Daily visits were made for a week.

The mean cost of food was 1·07 quetzal (1 Q = 1 U.S. dollar) per person per week in San Antonio and Q 0·95 in San Andrés. The main component of the diet was maize. The diet is described in detail. In relation to the recommended allowances of the U.S. National Research Council and FAO the mean intakes of energy, protein, Ca, Fe, vitamin B_1 and nicotinic acid were sufficient in both places, but intakes of vitamin A and riboflavin were low. The intake of vitamin C reached the recommended level in San Antonio, but only 65 per cent. of this in San Andrés. Of the total protein intakes of 69 and 72 g. daily, 10·4 and 7·7 g. were of animal origin.

4. The village of Santa María Cauqué lies on a sloping site about 1979 metres (6490 ft.) above sea level, and heavy rains from May to October cause much surface water to run down its farms, most of which are on the lower ground. There is a relatively good water supply to the village. The village has 706 inhabitants in 146 families, including 9 families of negro origin. The diet survey was made on 17 families of schoolchildren, 9 families classed as not poor and 8 as poor.

The diet is described in full. Intakes of energy, protein, Ca, Fe, vitamin B_1 and nicotinic acid were adequate ; those of vitamin A, riboflavin and vitamin C were not. About 10 per cent. of the protein was of animal origin.—D. Duncan.

MAYER, J., ROY, P. and MITRA, K. P. **Relation between caloric intake, body weight, and physical work : studies in an industrial male population in West Bengal.** *Amer. J. Clin. Nutrition*, 1956, **4**, 169–175. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Employees at a jute mill near Calcutta, all of whom were between 5 ft. 2 in. and 5 ft. 4 in. tall, provided, at interviews, records of their diets, budgets and family composition. There were 213 men and, from the detailed information available about their work and mode of life, they were classed as sedentary or as being engaged on light, medium, heavy or very heavy work. Data are tabulated for the average daily intake of 7 nutrients by 17 different occupational groups within these 5 classes. Intakes of total protein, three-quarters of it from vegetable sources, and of vitamins B_1 and C and nicotinic acid were considered adequate ; the intake of riboflavin, in the range of 0·6 to 1 mg., was low. Amounts of carotene and Ca also were small, but were influenced by the habit of chewing betel with lime. Energy intake was not related to income.

Mean values for energy intake are plotted for different degrees of activity. The amount of energy was least for the light work group, but was as high in the sedentary group as in the groups doing heavy or very heavy work. Bodyweight for the sedentary group was, on the average, about 25 lb. greater than for the others (cf. Review Article, pp. 877, 878, Vol. 25).

A comparison is drawn between these findings for men and those for rats (see Abst. 1040, Vol. 25).

JOLLIFFE, N. and TUNG, T. C. **Nutrition status survey of the civilian population of Formosa.** *Metabolism*, 1956, **5**, 309–327. [Bur. Nutrit., Dept. Health, New York.]

In a group of over 1000 urban and rural sixth grade children the incidences of nutritional deficiences were, per cent. : riboflavin deficiency 70, low excretion of vitamin B_1 in urine 55, Fe-deficiency anaemia 13, vitamin A deficiency 10, nicotinic acid deficiency 10, hypoproteinaemia 3·2. The clinical and biochemical findings from which these conclusions were drawn are tabulated. Data

are presented also for smaller groups of children in other grades, senior high school pupils, normal college students and adults. The incidence of beriberi was 6 per cent. in adults ; there was none in sixth grade children. Findings on height, weight and skinfold thickness, estimated daily intake of nutrients per head of the population and incidence of parasitic infestation are given as well. (See also Absts. 4956, 4957).—F. C. Aitken.

LEITNER, Z. A. and CHURCH, I. C. **Nutritional studies in a mental hospital.** *Lancet*, 1956, **270**, 565–567. [Claybury Hosp., Woodford Green, Essex.]

Average daily intakes of energy, protein, fat and carbohydrate in a mental hospital for each of the months October 1951 to September 1952 were calculated from measurements of all food delivered to the kitchen, with deduction for plate waste. Periodical measurement of plate waste indicated that this amounted to about 10 per cent., rarely up to 15 per cent. by weight of the served food. Intakes of energy and proximate principles appeared satisfactory.

Studies were made of Hb, prothrombin time, level of carotenoids and vitamin A in blood and of ascorbic acid saturation tests and the results are tabulated. Hb, carotenoids and vitamin A in blood were low and responses in ascorbic acid saturation tests were delayed. These findings, with clinical signs of ascorbic acid deficiency, follicular hyperkeratosis, gingivitis and petechial haemorrhages not apparent in all and the last only in men working in the garden, and the striking rise in carotenoids and vitamin A in the blood of patients given a daily helping of carrots or spinach, indicated some of the inadequacies of the diet.

It is suggested that all patients in mental hospitals should be given a supplement of 50 mg. ascorbic acid daily and that the supply of leafy green vegetables should be increased.

VAN BERGE, A. W. S. De voeding in enige tehuizen voor bejaarden in Nederland. [**Diet in some homes for old people in the Netherlands.**] *Voeding*, 1956, **17**, 174–195. [Voorlichtingsbur., Voedingsraad, The Hague.] English and French summaries.

A diet survey was made in 29 homes for old people where 1004 men and 1243 women, healthy and over 60 years of age, were living. For daily energy intake the Dutch Nutrition Council has recommended 1800 Cal. for women and 2400 Cal. for men in old age. The range found was from 1287 to 2503 Cal. but extra sweets, cakes and fruit may have supplied from 150 to 300 more Cal. daily. On the average the sources of calories were 12 per cent. from protein, 35 per cent. from fat and 53 per cent. from carbohydrate. The proportion from fat was high but was that to which the inmates were accustomed. They accepted vitaminised margarine in place of cooking fat but were reluctant to take the recommended amount of milk, 3/4 litre daily. Suggestions are made for improvement of the diets in these homes.

ABBOTT, O. D., TOWNSEND, R. O. and FRENCH, R. B. (with MARSHALL, O. and NEELANDS, E.) **Dietary and hematologic studies of the aged.** *Univ. Florida Agric. Exp. Stat. Bull.* No. 562, May 1955, pp. 16.

A group of 306 men and women, ageing under favourable environmental conditions, was selected for study. Individual 7-day diet records were obtained from 251 of them. The nutrients compared well with the U.S. National Research Council's recommendations except that energy intake by the men was 20 per cent. below the standard. The means for Hb of men and women were within the normal range ; it appeared that standards for Hb derived from younger groups were applicable to this group of elderly people. No significant difference in red cell counts or in total or differential leucocyte counts, attributable to age or sex, was found. There was no close relation between Hb value and Fe intake. Subjects with low Hb with or without a low red cell count responded to treatment with haematinic preparations, which is taken to show that low values were due not to ageing but to some other cause, such as faulty absorption or impaired utilisation.

Characterization of thresholds and stages of development in the bioeconomic mechanism.** *Amer. J. Med. Sci.*, 1956, **231**, 407–426. [Nat. Committee on Maternal Health, Inc., 2 East 103rd St., New York 29.] Interlingua summary.

For previous parts see Absts 965, 2269, Title 3576, Vol. 26.

4. This analysis of successive stages of biological and economic development and their interactions includes diagrams in which birth rate and death rate, both before and after the war, life expectancy, infant mortality (data from *U.N. Demographic Yearbook*, 1953) and the authors' Situation Index (see Abst. 965, Vol. 26) are plotted against daily calorie intake per person for numerous countries and territories (data from *FAO World Food Survey*, 1952). Birth rate is a maximum at about 2000 Cal., death rate becomes stable at about 2400 Cal., full health is believed to be attainable at some point between 2400 and 2700 Cal. and life expectancy is a maximum at about 2700 Cal. It is suggested that the turning point from subsistence to socio-economic and cultural development occurs when daily intake per person is about 2700 Cal., average annual income is equivalent to about 300 U.S. dollars and yearly industrial energy consumption per person is equivalent to about 1·4 ton of coal.—W. M. Deans.

MUSZKATOWA, B., RUDOWSKA-KOPROWSKA, J. and SZKIŁŁĄDZIOWA, W. Zestawy kulinarne o wysokiej wartości biologicznej białek otrzymanejprzez wykorzystanie ich wzajemnego uzupełniania się. [**Meals of high biological value as a result of supplementation of their proteins.**] *Rocz. Państwowego Zakł. Hig.*, 1956, **7**, 123–139. Russian and English summaries.

Tables showing limiting amino acids and biological values of proteins were used to examine the effect of substituting vegetables for animal products on the calculated biological value of proteins in a meal. The reference meal was 100 g. meat or 2 eggs, with 300 g. potatoes or 70 g. wheat flour; 65·7 per cent. of the total protein was of animal origin. Pulses were first substituted for animal foods. When soya bean protein replaced $\frac{1}{2}$ or $\frac{3}{4}$ of the egg protein the biological value of protein in the meal was reduced from 82 to 72 in each case; navy bean protein reduced it to 66 and 64. Replacement of meat by navy bean protein had little effect; pea protein reduced the biological value of the meal from 72 to 59 and 50. When wheat flour replaced potatoes the biological value of protein in the meal was less, especially if it contained navy beans.

In the second series yeast and wheat flour protein were used as substitutes for egg and cheese. The standard meal was of egg, cheese and wheat flour; 53·1 per cent. of the total protein was of animal origin. When yeast was substituted for cheese, 9·1, 41·0 and 46·9 per cent. of total protein being supplied by egg, yeast and wheat flour, respectively, the biological value of the meal was reduced from 66 to 55. Replacement by wheat flour, 16·2 and 83·8 per cent. of total protein being supplied by egg and wheat flour, respectively, reduced the biological value of the meal to 35.

Meals containing dishes made up of these ingredients were served to a tasting panel and found attractive after some modifications.

The biological values of protein in typical meals were tested also by the rat growth method. Meals containing meat, eggs and pulses showed experimental results lower by a few percentage units than the calculated values. Meals containing mainly cereal products (second series) showed results several percentage units higher than the calculated values. This discrepancy is explained on the grounds that rats require relatively less lysine than man.

The conclusion is that meals in which vegetable proteins are substituted for animal proteins along the lines indicated have biological values of the total proteins comparable to that of meat alone.—W. Z. Billewicz.

FOOD ECONOMICS AND STATISTICS

4945

JURÉEN, L. **Long-term trends in food consumption: a multi-country study.** *Econometrica*, 1956, **24**, 1–21.

Statistical data are available for 16 European countries and for the United States showing prewar energy intake per head daily within 2 groups of foods, animal foods and residual items. It is found that energy intakes are clearly dependent on the corresponding average values of real income per head of population, and simple hyperbolic demand curves have been fitted to the data for total calories and animal products. The difference between these two hyperbolic curves represents the demand function for "vegetable products", *i.e.*, all residual items. Some of the larger discrepancies between the demand curves and the original data are explicable in terms of the climates of the countries concerned or their importance as producers of animal food. Similar demand curves are obtained from post-war data, showing that they are stable in time; such evidence as is available suggests that they can be applied also within single countries to furnish quantitative information about probable differences in food consumption between classes of the population, and about long-term trends in consumption.

Income elasticities have been calculated from the multi-country demand curves. The demand for animal foods increases with income, but the elasticity is much less at higher income levels. For "vegetable products" the demand is almost inelastic except at very low levels of income. The most important item included is cereals, for which the demand rises with income at very low levels, then flattens and falls again at medium and high levels of income. For total energy intake the elasticities confirm the well known fact that it has almost reached a maximum in the rich countries but that in the poorest countries some increase is to be expected if economic conditions improve. For accurate estimates of trends in food consumption it would be necessary to know how the distribution of income in the country, as well as its average amount, was likely to change.

There is a discussion of the problem of obtaining price elasticities of demand; estimates are made although primary data available for this purpose are judged to be far from sufficient. It is concluded that in North-western European countries the demand for animal foods has a significant negative price elasticity but is practically independent of changes in cereal prices. On the other hand, the demand for cereals and potatoes has a

very small price elasticity but is highly dependent on animal prices. The demands for fruit and vegatables are sensitive to price changes; total energy intake is not.

A summary is given of the developments in food consumption in Western Europe since the middle thirties. The long-term tendency, somewhat masked by changes in inter-food price relations, has been for feeding standards to improve substantially with the gradual rise in incomes. This tendency continues, and would be strengthened if price relations returned towards those existing pre-war.

4947

WAUGH, F. V. **A partial indifference surface for beef and pork.** *J. Farm Econ.*, 1956, **38,** 102–112. [Agric. Marketing Serv.]

This paper suggests a method of handling empirical data so as to provide statistical estimates of use in the study of problems which arise when two or more commodities compete with one another.

The data used in illustration are the annual consumptions, by weight per head, of beef and of pork in the United States between 1932 and 1941, their average retail prices and average disposable incomes per head in each year. A very good fit to these data is found by an equation of the form

$$r = aq_1^b q_2^c y^d$$

where r = price ratio of beef to pork, q_1 = per caput consumption of beef (lb.), q_2 = per caput consumption of pork (lb.), y = disposable income per caput (dollars) and a, b, c, d are constants fitted to the data.

This equation is used to eliminate the small effect of the variations in y from year to year, by calculating the values

$$r' = aq_1^b q_2^c (490{\cdot}9)^d$$

where 490·9 dollars was the average disposable income over the period. Cartesian co-ordinate axes q_1, q_2 and z are now taken, where z is a function of q_1 and q_2 chosen so as to define a surface whose contours on the q_1q_2 plane pass through the plotted consumptions of beef and pork in each year with slopes equal to the negatives of the estimated adjusted price ratios, r'. The diagram showing these contours is what the author calls a partial indifference surface for beef and pork. The diagram can be imagined to be a cross-section of an assemblage of such diagrams, for different values of disposable income, in which the contours would link to form a family of three-dimensional surfaces. Arguments are put forward in favour of the identification of this construction with a partial indifference surface, and it is shown in particular that the observed data are statistically consistent with the hypothesis that the function z is a monotonic function of utility.—I. McDonald.

STOLTING, W. H., GARFIELD, M. J. and ALEXANDER, D. R. **Fish and shellfish preferences of household consumers.** *U.S. Dept. Interior, Fish and Wildlife Serv. Res. Report* No. 41, 1955, pp. 115.

4949

BELTRÁN, R. Futuras orientaciones sobre la industria de la alimentación. [**Future trends of the food industry.**] *An. Bromatol.*, 1956, **8,** 123–143. [Inst. Nac. Indust.] English summary.

The Spanish diet provides, with a predominance of carbohydrates, 2680 Cal. per head daily. It is considered inadequate in energy value, animal protein, Ca and vitamin A, and in infants signs of deficiency are common. The mean cost of the family diet is 39·6 pesetas daily, but 60 pesetas has been estimated to be the cost of the cheapest adequate diet. The percentage of the total income spent on food varies, according to social class, from 87 to 49 with a mean about 75. To buy 1 kg. meat in Spain it is necessary to work for 9 hr., compared with 1 hr. 5 min. in America (U.S.) and 1 hr. 46 min. in Great Britain.

In Spain attention should be paid to the technical side of the food industry to prevent losses of vitamins and minerals. The milk industry is much neglected, especially in the development of pasteurisation and similar techniques. Industrial refrigeration is being studied, and so to some extent are new methods of dehydration and electrical treatment of foods. Use of new sources of protein such as yeasts, and the recovery of waste materials, are briefly discussed and the need for capital for their development is reviewed.

D. Duncan.

4950

TARVER, J. D. **Costs of rearing and educating farm children.** *J. Farm Econ.*, 1956, **38,** 144–153. [Oklahoma Agric. and Mech. Coll.]

The estimates are based on data for 1941 on expenditure of a representative sample of farm families in the United States (*U.S. Dept. Labor Bull.* No. 822, 1945, p. 75). For a typical farm family of husband, wife, son aged 13 and daughter aged 7, food accounted in 1941 for $589 out of a total of $1344 (which included $521 for value in kind). Recalculated for 1954 retail prices on the assumption that spending habits have not changed, food would have accounted for $1240 out of $2829.

The yearly cost of food (the requirement of a child as a fraction of that of an adult male being taken from the report of Stiebeling *et al.* (Abst. 2409, Vol. 11)) and of other items is tabulated for the sexes separately up to age 29. The yearly cost of food rises steadily to a maximum between the ages of 16 and 19, $380 for a boy, $336 for a girl. The total cost of rearing to the end of the 18th year was for a boy $15,281, or, deducting the estimated value of his labour, $11,497; for a girl $15,178, less $820 (no estimate was made of the value of housework).—W. M. Deans.

GENERAL STUDIES

4952

BERNHEIM, M., FRANÇOIS, R., VINCENT, P. and RUITTON-UGLIENGO. Dystrophie oedémateuse d'origine alimentaire chez un eczémateux. Ses rapports avec le syndrome "kwashiorkor". [**Dystrophy with oedema of dietary origin in a patient with eczema. Relation to the kwashiorkor syndrome.**] *Pédiatrie*, 1956, **11**, 356–359.

A syndrome closely resembling that of kwashiorkor appeared in a child aged 1 year after it had been fed for 3 months on water and vegetable soup. After 2 plasma transfusions, treatment with a high-protein diet led to rapid improvement. Blood proteins are often low in patients with eczema even when they are well fed.—L. Wills.

4953

JEUNE, M., CARRON, R. and GAUTHIER, J. Sur 7 cas de dystrophie nutrionnelle oedémateuse d'origine alimentaire chez des nourrissons eczémateux. [**Seven cases of oedematous nutritional dystrophy of dietary origin in infants with eczema.**] *Pédiatrie*, 1956, **11**, 359–362.

In 7 infants with eczema, aged from 4 to 18 months, the typical syndrome of nutritional oedema of the kwashiorkor type appeared after from 15 days to 13 months of diets grossly deficient in protein. The pathological and biochemical findings were typical of kwashiorkor but, in addition, 3 infants showed signs of rickets, 4 had albuminuria and in 2 of 3 examined urinary excretion of amino acids was above normal. Further, of 8 patients with eczema but no oedema, 6 showed an increase of amino acids in the urine which was not related to the plasma protein concentration, though in one the loss of amino acids decreased as the plasma proteins increased. There was some relation between that increase of amino acids and the presence of rickets. The condition was considered to differ from kwashiorkor only in degree.

L. Wills.

4954

OLIVÉ BADOSA, A. Nueva versión patogénica de la distrofia nutritiva del lactante. La distrofia, enfermedad de adaptación. [**New version of the pathogenesis of nutritional dystrophy of infants. Dystrophy as a disorder of adaptation.**] *Rev. clín. española*, 1956, **61**, 30–36. [Clín. Pediát., Hosp. Sta. Cruz y S. Pablo, Barcelona.] English, German and French summaries.

Nutritional dystrophy in infants may have a number of causes, such as inadequate intake of energy, protein, carbohydrates, or vitamins, infections or metabolic abnormalities, but the clinical picture is always much the same. It includes diminution or absence of subcutaneous fat, slow circulation, bradycardia, low blood volume and pressure, slow respiration, anoxaemia, reduced haemopoiesis, low blood protein, oliguria, hypothermia, reduced immunity related to low γ-globulin levels and altered metabolism. By some it is regarded as a "static" condition but, in the author's view, it should be looked on as an "active" reaction by which the body defends itself against expenditure of energy. He compares it with "permanent shock" or "autohibernation". The components of the condition are discussed in relation to Selye's general adaptation syndrome. [The literature is discussed, but there is no bibliography.]—D. Duncan.

4955

BELL, L. H., MEADE, E. M. and SPENCER, J. C. **Social and economic background of children attending L.C.C. Nutrition Clinics.**] *Med. Officer*, 1956, **95**, 162–169. [Dept. Social Sci., London Sch. Econ.]

The numbers of children referred to the nutrition clinics in each of the years 1949, 1950 and

1951 were more than double the number referred in 1937. The rise is not attributed to an increase in the incidence of malnutrition but possibly to rising standards set by school doctors and parents and to a change in the type of case sent to the clinic. The children were selected partly on weight relative to height, partly on clinical grounds. The records of 100 children were examined in 1952. Graphs of height-weight-age relationships are presented to show that, with few exceptions, the children were both short and thin for their age compared with the averages for London County Council children in 1949, but, again with few exceptions, rate of growth was normal while the children were attending the clinic. Evidence of past rickets was seen in 8 per cent., compared with 44 per cent. in a group of 50 children attending one of the clinics before the war. The social and economic environment was unfavourable in 57 and seriously so in 19 cases. In 13 the main finding was a history of premature birth or of serious or recurrent illness. In 11 there was some evidence of emotional and behaviour difficulties although conditions were good.

The functions of the clinics are discussed.

[Dept. Med., Post-Grad. Sch. Med., Univ. New York ; Med. Nutrit. Lab., Fitzsimmons Army Hosp., Denver, Colo.]

1. In May and June 1954 a survey was made of the rationing system of the Chinese Republican Army in Formosa. Clinical examinations of 711 men drawn from units serving under widely different conditions showed that signs of deficiencies of riboflavin, nicotinic acid and vitamin A were common. Nutritional oedema was never seen and, although the vitamin B_1 content of the diet was suspected to be low, no beriberi was found. The average weight was 126 lb., height 65·6 in., surface area 1·62 sq. m. and age 28 years. The staple in their diet was rice, 848 g. (27 Chinese oz.) daily for officers and enlisted men and 14, 10 and 5 kg. monthly for adult, youth and infant dependents, respectively. Extraction rate for the rice was 93 or sometimes 90 per cent. Other foods issued generally were edible oil and salt ; serving soldiers got small amounts also of fish and pork. A money allowance was given with which vegetables were bought ; hence the amounts varied with the price. The amount of Ca in the diet was increased by the use of " stone powder " to facilitate the flow of rice during milling and to whiten the product. This powder produced alkalinity and consequently caused some destruction of vitamin B_1.

From these findings certain changes were recommended, of which the most important were reduction of the rice to 656 g. (21 Chinese oz.) daily, and addition of 200 g. yellow sweet potato and of an enrichment mixture to provide daily 2·1 mg. vitamin B_1, 5·4 mg. riboflavin, 20 mg. nicotinic acid and 14 mg. Fe per head. It was suggested also that the effects as a vermifuge of the mass use of single doses of hexylresorcinol should be studied. With this aim 12 companies were set up and, with suitable precautions for separate feeding, 6 were given the regular and 6 the enriched ration ; in each of these groups 3 companies were given 1 g. vermifuge and 3 remained infested. The total number of subjects was about 1200 and the experiment lasted from October 1954 to February

1955. The following abstracts refer to the findings in this mass experiment.

2. Over the whole period of the experiment mean daily intakes per man were, for the control group, vitamin A nil and carotene 3·77 μg., vitamin B_1 1·48, riboflavin 0·86 and ascorbic acid 68·1 mg.; for the group on the enriched diet, corresponding amounts were nil and 5·98 μg. and 3·55, 4·56 and 93·4 mg. Samples of blood and urine were collected from 380 soldiers before the experiment began and again in its last week. On these occasions mean values for the control and experimental groups, irrespective of treatment with vermifuge, were, vitamin A 26·6, 25·2 and 26·5, 32·0 μg. and carotene 32·2, 43·7 and 28·7, 74·1 μg. per 100 ml. serum: ascorbic acid 0·289, 0·534 and 0·395, 0·933 mg. per 100 ml. blood and 0·130, 0·242 and 0·209, 0·859 mg. per hr. in urine; vitamin B_1 2·81, 5·49 and 2·42, 35·43, riboflavin 5·82, 4·78 and 5·17, 63·94, N^1-methylnicotinamide 194·9, 330·9 and 221·3, 898·0 μg. per hr. in urine: Hb 15·5, 15·0 and 15·3, 14·8 g. per 100 ml.: haematocrit 46·0, 44·4 and 44·5, 43·8 per cent.: serum proteins 7·63, 6·79 and 7·57, 6·79 g. per 100 ml.

It was concluded that carotene from yellow sweet potato was readily absorbed, that enrichment corrected the biochemical deficiencies, that the protein content of the diet was normally adequate and, from comparison with similar values reported by other investigators, that the level of enrichment was unnecessarily high.

3. The procedure during the clinical examination and the system of recording results are described. The findings are summarised in 9 tables for the individual companies and are grouped to show the numbers of subjects, as percentages of the total, in whom the particular condition was found at the start and at the end of the experiment. The numbers of men examined were 542 on the control and 507 on the experimental diet.

Tongues were normal in 1·8 and 1·1 per cent. of the control and in 1·8 and 31·5 per cent. of the experimental group at the beginning and end of the test, respectively. Corresponding percentages for other conditions in the same order were: extensive tongue lesions 44·8, 69·3 and 47·3, 20·7; acne of face 16·2, 19·3 and 17·3, 4·5; naso-labial seborrhoea 80·6, 82·8 and 82·0, 22·2; angular stomatitis 70·4, 78·7 and 71·7, 18·1; scrotal dermatitis 18·1, 36·9 and 16·0, 1·9. There was evidence that with change of diet there was less bleeding in the gums; effects on hyperaemia, oedema, recessing of gums and gingivitis were not significant. The findings for follicular keratosis on 6 areas were difficult to interpret in relation to trauma. Nutritional oedema and calcium deficiency were not recorded and, unexpectedly, only 1 case of suspected beriberi was found.

Enrichment of rice is considered applicable under these conditions of army service; civilian populations might be prejudiced against the colour which the added riboflavin imparts. With 93 per cent. extraction and cooking of rice in water not made alkaline by "stone powder", addition of vitamin B_1 would not be necessary.

4. The foods used and the methods of preparation of the meals are described. From detailed studies of the amounts issued, or purchased by the men with their money allowance, and from analyses of sample meals, the daily intakes of nutrients were calculated to be, for the regular ration, energy 3610 Cal., protein 95, fat 77 and carbohydrate (by difference) 630 g., vitamin A none, carotene 3·77, vitamin B_1 1·43, riboflavin 0·86 and vitamin C 68 mg. For the enriched ration corresponding values were 3380 Cal., 105, 60 and 605 g., none, 5·48, 3·35, 4·55 and 93 mg.

The proposed enriched diet was palatable and acceptable to the troops; its cost was comparable with that of the regular diet.

5. Energy exchange was studied with the Müller Franz respirometer (see Abst. 3943, Vol. 23) and by time and motion studies in 20 men in training. Ten had the regular and 10 the enriched diet. On 2 days of the week they marched for 8 hr. with short rests and on 4 days they marched for 4 hr. and spent 2 hr. at sports; the seventh was a day of rest. Tables show the time spent in 23 different activities and the B.M.R. and energy cost of 19 types of activity. These metabolic rates are compared with similar data for Japanese, American and British subjects. For all subjects the average energy intake was 3610 Cal. on the control and 3380 Cal. on the enriched diet. Energy expended daily by the groups was, on the average, 3307 and 3138 Cal. in the same order. When changes in bodyweight were taken into account the energy balance unaccounted for was within the limits of accuracy of the technique. Analysis of the data showed that performance by the men on the enriched diet was better than by those on the regular diet by an amount which was statistically significant, a finding which is in contrast with the results of earlier work from the same laboratory (see Abst. 5115, Vol. 24) in which, with well nourished subjects, massive doses of vitamins were found not to increase efficiency of work.

6. The data for height, weight and skinfold thickness from paper 3 were analysed. The mean values for the numbers of troops in the 4 groups according to diet and vermifuge treatment were: 273 men, regular ration, no vermifuge, age 26·7 years, height 164·9 cm., weight at beginning 55·7 and at end of experiment 55·4 kg., skinfold thickness, sub-scapula 0·80 and mid-arm 0·42 cm.; 269 men, regular ration, with vermifuge, 27·0

years, 164·0 cm., 56·2 and 56·1 kg., 0·80 and 0·42 cm.; 256 men, enriched ration, no vermifuge, 27·0 years, 164·0 cm., 55·8 and 55·0 kg., 0·79 and 0·41 cm.; 251 men, enriched ration, with vermifuge, 26·8 years, 165·0 cm., 55·9 and 55·4 kg., 0·78 and 0·43 cm. The differences between the groups were not statistically significant. Compared with American recruits accepted for military service the Chinese soldiers were about 3 in. shorter and 27 lb. lighter and had smaller skinfold thicknesses.

7. The basic problem is to define the amount and kind of substitutes for rice and to decide the extent to which they should be used and the level below which consumption of rice should not be allowed to fall.

8. Blood proteins, estimated at the end of the experiment by the Kjeldahl method, were on the average for the control group 7·04 and for the group on the enriched diet 6·91 g. per 100 ml. serum; the copper sulphate method gave 6·79 g. for both groups (see paper 2). Mean values for the fractions measured by paper electrophoresis were for the 2 groups, respectively, in g. per 100 ml., albumin 3·41, 3·44; globulin, α_1 0·256, 0·271, α_2 0·602, 0·555, β_1 0·990, 0·903, β_2 0·014, 0·031, γ 1·768, 1·711. Total globulin was 3·639 and 3·470 and albumin : globulin 0·956 and 1·005, respectively. The difference from American values was largely in the higher γ-globulin fractions and in a correspondingly lower albumin : globulin ratio.

For lipids mean values were for the control group 657·2 and for the group on enriched diet 635·1 mg. per 100 ml. serum. Both are higher than the average quoted (see Boyd, Abst. 369, Vol. 12) for Americans whose diets are likely to contain about twice as much fat (Consolazio *et al.*, *Nutrition survey of two consecutive cycles of the airborne training Bn. Co., "G", Fort Benning, Ga.* MNL Report 166, 1955). Serum lipids were above 700 mg. per 100 ml. for 56·6 per cent. of the control and 53·7 per cent. of the experimental subjects.

9. Clinical signs were given arithmetical values and a technique of squaring was devised in order to weight them for importance of, for example, site or degree. These basic data are tabulated with the correlation coefficients which were calculated between incidence of a sign and vitamin intake. There was a close relation between intake of riboflavin and occurrence of cheilosis, magenta colour of the tongue, papillary atrophy of the tongue and scrotal dermatitis; between intake of nicotinic acid and incidence of filiform and fungiform papillary lesions of the tongue. Intake of carotene was inversely related to follicular keratosis on chest, arms, back and buttocks. The signs of nutritional deficiency tended to disappear in soldiers given the enriched diet.

10. The composition of more than 100 Formosan foods is given in terms of moisture, fat, protein, ash, vitamins A, B_1 and C, carotene and riboflavin. Scientific names are given. Data are tabulated also for moisture, fat and protein in a total of 58 samples of 45 cooked foods.

11. Each of 1049 soldiers underwent an eye examination. Trachoma was the commonest disease but not a frequent cause of blindness. Most visual defects could be explained by local conditions. In general vision was good. Optic atrophy and unexplained poor vision may have been the result of severe deprivation some years earlier.

12. Examinations of stools were made twice, first before half the men were given the hexylresorcinol, and four months later. The methods are described and the system of recording intensity of infestation with hookworm, Trichuris and Ascaris is shown. Loss of bodyweight was greater in untreated than in treated companies and its relation to hookworm intensity was significant at the 5 per cent. level. There was no correlation between infestation and the incidences of angular stomatitis or of papillary lesions of the tongue or between infestation and excretion of riboflavin or of N^1-methylnicotinamide in urine.—D. Harvey.

LAMBOTTE-LEGRAND, J. and LAMBOTTE-LEGRAND, C. Activité et problèmes pédiatriques au Centre extra-coutumier de Léopoldville. [**Activity and paediatric problems at the extra-tribal centre of Léopoldville.**] *Ann. Soc. belg. Méd. trop.*, 1955, **35,** 725–745. Flemish summary.

The population of Léopoldville has increased threefold in 8 years and children constitute one-third of it. Infant mortality has decreased but is still high. The causes are considered. Prematurity ranks high as a cause, but malnutrition in children seems to be rare.—E. M. Hume.

4959

HOLEMANS, K. and ANDRÉ, J. Considérations sur l'absence de la toxicose éclamptogène en

milieu rural au Congo Belge. [**Absence of eclampsia in rural districts of the Belgian Congo.**] *Ann. Soc. belg. Méd. trop.*, 1955, **35,** 583–589. Flemish summary.

To find a possible relation between diet and the occurrence of eclampsia among Europeans, studies were made in the Kwango of rural people among whom the disorder is not found. Calcium does not exceed 400 mg. daily, but this low intake is thought unlikely to contribute. The disorder does not occur where the intake of protein is very low, but in the cities, where the intake is higher, eclampsia does appear. In the Kwango consumption of salt is only 4 g. daily, about one-quarter that of Europeans (see Abst. 4581, Vol. 26).

In Feshi weights were recorded for 700 non-pregnant Basuku women and for 81 pregnant women, just before, shortly after and again 10 days after delivery. The gain of weight during pregnancy was much less than in American women. Excretion of urine by Basuku women did not fall during pregnancy (see Abst. 4581, Vol. 26).

The tentative conclusion is that in white women the much greater intake of salt and consequent greater retention of water may be significant in connection with the occurrence of eclampsia.

BELL, S. **The Ameru people of Kenya : a medical and social study. 1. Geographical and ethnological background. 2. The medical background. The changing background. 3. Materials and methods of study. 4. Anthrax, treponematosis. 5. Treponematosis. 6. Pulmonary tuberculosis. 7. Relapsing fever. 8. Malaria. 9. Ascariasis. Taeniasis. Ancylostomiasis. Conclusion.** *J. Trop. Med. Hyg.*, 1955, **58,** 223–239 ; 249–259 ; 280–290 ; 1956, **59,** 5–14 ; 31–40 ; 57–65 ; 82–88 ; 106–112 ; 121–133. [Dept. Clin. Trop. Med., London Sch. Hyg. Trop. Med.]

The Ameru are a Bantu people numbering, by the 1948 census, about 310,000 and living in an area of about 1450 sq. miles north-east of Mt. Kenya. This series includes brief references in part 1 to the feeding of infants, young girls and warriors and in part 2 to the preparation of foods. In part 9 one conclusion is that intake of protein of low quality from maize and deficiencies of calcium and of fat-soluble vitamins are conditions affecting the course of disease especially among vulnerable groups in seasons when the rains fail.

HEUPKE, W. and FISCHER, H. Kann die Zahl der Gallensteinträger vermindert werden ? [**Possibility of reducing the number of those with gall-stones.**] *Münch. med. Wochenschr.*, 1956, **98,** 194–196. [Hosp. zum Heiligen Geist, Frankfurt a.M.] English and French summaries.

The medical field is surveyed from the point of view of formation of gall-stones as the result of overfeeding. Gall-stones are generally composed almost entirely of cholesterol. The number and severity of cases declined during the second world war. In obesity, pregnancy and diabetes, in which there is a high incidence of cholelithiasis, consumption of foods rich in cholesterol tends to be high. Geographical survey shows gall-stones to occur much more frequently in temperate regions where animal fats containing cholesterol are eaten than in tropical countries where the fats are chiefly vegetable oils free from cholesterol. It is therefore considered that when inflammatory or other changes are present in the gall-bladder and the gall-duct a diet rich in cholesterol has much to do with the formation of gall-stones and the tendency should be counteracted by a diet low in cholesterol. The cholesterol contents of some animal fats is given.—E. M. Hume.

4962

HAYES, O. B., BOWSER, L. J. and TRULSON, M. F. **Relation of dietary intake to bone fragility in the aged.** *J. Gerontol.*, 1956, **11,** 154–159. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Diet studies were made by the interview method of 16 male and 31 female patients in hospital with fracture of the femur and of the same numbers of control subjects selected from a random sample of 100 old people living at home. All the subjects were over 65 years of age and had been or were at least moderately active ; the normal subjects were free from major illness and had no history of fractured bones.

There was no significant difference between the eating habits of the groups, nor had there been a significant difference in their milk intake during childhood. There was some evidence that the patients with fractures were underweight compared with the control subjects.—G. F. Garton.

SUMMERSKILL, W. H. J., DAVIDSON, E. A., SHERLOCK, S. and STEINER, R. E. **The neuropsychiatric syndrome associated with hepatic cirrhosis and an extensive portal collateral circulation.** *Quart. J. Med.*, 1956, **25,** 245–266. [Dept. Med., Postgrad. Med. Sch., London.]

The neurological and psychiatric changes which occurred in 17 patients, of whom 5 have already

been described (Sherlock *et al.*, *Lancet*, 1954, **267**, 453) are given in detail. All had chronic liver disease. In 15 patients the existence could be demonstrated of an extensive portal-systemic collateral circulation which in 5 had arisen from occlusion of the portal vein by thrombosis and in 4 followed surgical operations. The degree of mental disturbance ran parallel to the intake of N; all 17 responded to restricted intake of protein. In 15 patients the condition deteriorated when they were tested with a diet rich in protein. It is suggested that the existence of the portal collateral circulation allows a toxic substance or substances, absorbed from the intestine, to reach the brain by the systemic system.—D. Harvey.

4964

FISCHER, H. Pathologisch-anatomische Befunde nach schwerer alimentärer Dystrophie. [**Pathological anatomy after severe nutritional dystrophy.**] *Deutsch. Ztschr. Verdauungs- u. Stoffwechselkr.*, 1956, **16**, 103–111. [Pathol. Inst., Univ. Munich.]

The findings post mortem in 92 men who returned from prisoner-of-war or concentration camps are described and discussed. The most frequently occurring causes of death were: carcinoma and sarcoma, ages 23 to 58, 19; chronic endocarditis 18, tuberculosis 13 and other diseases of the lungs 8. The proportion of endocarditis is far above expectation. Atherosclerotic changes were in general slight.—I. Leitch.

SAPIN-JALOUSTRE, J. and SAPIN-JALOUSTRE, H. La pathologie en expédition polaire antarctique. A propos des observations de la 1re expédition en Terre Adélie (1948–51). [**Pathology on an Antarctic polar expedition. Observations on the first expedition to Adélie Land (1948–51).**] *Presse méd.*, 1956, **64**, 579–582; 637–640; 791–794; 821–823.

A review is presented of the pathological states reported by earlier expeditions with notes on those encountered by the French group who visited Adélie Land in 1948–51 in preparation for the International Geophysical Year. The finding which had nutritional significance for this expedition was that, when supplies of pharmaceutical vitamin preparations failed for a month, vitamin C saturation tests showed by delay in saturation that, without these, the intake of ascorbic acid from the diet was not quite adequate although rations did include orange drinks fortified with vitamin C.

BROCK, J. F., HANSEN, J. D. L. and HOWE, E. E. **The role of amino acids in kwashiorkor.** *Amer. J. Clin. Nutrition*, 1956, **4**, 286–287. [Dept. Med., Univ. Cape Town.]

As criteria of the initiation of cure of kwashiorkor (see Abst. 998, Vol. 26) a rise in albumin and, in some cases, in amylase content of serum may be useful. Further tests have been made of this initiation produced by a mixture of 18 amino acids forming 59·5 per cent. of the diet or one of 11 acids forming 16 per cent., the first given with a vitamin mixture and the second with or without it. From the results it seemed that with the smaller group of acids the lower limit of efficacy was being reached and that the vitamin mixture might influence the efficiency of utilisation of amino acids.

4969

PRETORIUS, P. J., DAVEL, J. G. A. and COETZEE, J. N. **Some observations on the development of kwashiorkor. A study of 205 cases.** *S. African Med. J.*, 1956, **30**, 396–399. [Dept. Paediat., Univ. Pretoria.]

The patients were 200 Bantu and 5 Coloured children admitted to Pretoria Hospital in 1954 and 1955. In age groups they numbered under 1 year 26, 1 to 2 years 138, 2 to 3 years 30 and over 3 years 11; none was under 6 months or over 5 years. The incidence of kwashiorkor was unrelated to sex. Their diets had been rich in carbohydrate and poor in protein and had included little vegetables and fruit; 12 children were still being breast fed. The disease usually appeared

from 1 to 6 months after weaning. Data for social conditions, incidence of bacterial infections of respiratory system and digestive and urinary tracts, of intestinal parasites and of venereal disease are summarised.

The conclusions are that in the etiology of kwashiorkor socio-economic conditions lead to a cheap diet poor in protein and, more tentatively, that susceptibility to infection may create still greater demands for protein in the diet.

VARGHESE, K. M. **Nutritional oedema (among children in the K.D.H.P. Co. Ltd., Tea Estates, High Range, T-C. State).** *Antiseptic*, 1956, **53**, 293–296. [Chokanad Estate, Munnar P.O., Travancore-Cochin, India.]

4971

MEHTA, G., VENKATACHALAM, P. S. and GOPALAN, C. **Steatorrhoea in nutritional oedema syndrome (kwashiorkor).** *Indian J. Med. Res.*, 1956, **44**, 231–235. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor.]

When faeces from 6 children with nutritional oedema were examined by microscope, fat globules were seen to be abundant. The effect of different diets on excretion in faeces of total and neutral fat was studied and the iodine values of dietary and faecal fats were estimated. When the diet was low in fat more was excreted than was ingested and, as judged by iodine values, dietary and faecal fat bore no relation to one another. Increased intakes of fat or of glucose led to greater excretion of fat. Groundnut oil increased faecal fat to a greater extent than did an equal amount of butter.

The fat in the faeces of these subjects was considered to be partly endogenous and partly exogenous in origin.

Steatorrhoea was not aggravated by wheat in the diet and folic acid had no beneficial effect on it.

4972

VINCENT, G. Hypoprotéinémie nutritionnelle infantile à la Réunion : le kwashiorkor. [**Low blood protein values of nutritional origin in infancy in Réunion: kwashiorkor.**] *Méd. trop.*, 1956, **16**, 241–251. [Corps de Santé Colonial.]

Kwashiorkor was common, mainly in white or coloured children; infants of the black race were seldom affected. The basic diet after weaning was chiefly maize or rice. The number of cases varied with the season, probably because of seasonal variation in income and therefore in food rather than because of climatic changes. An unusual finding was that the concentration of γ-globulin in the serum frequently was normal or low, a result which, in the author's opinion, was possibly associated with the absence of malarial infection in the patients in Réunion. In no case was the liver clinically enlarged. In addition to the usual treatment with a high-protein diet, Syncortyl was given daily because of signs of adrenal insufficiency.—L. Wills.

4973

WALT, F., HOLMAN, S. and HENDRICKSE, R. G. **Megaloblastic anaemia of infancy in kwashiorkor and other diseases.** *Brit. Med. J.*, 1956, i, 1199–1203. [Dept. Paediat., McCord Zulu Hosp., Durban.]

Examination of bone marrow smears from 776 children admitted to hospital showed that 42, of whom 40 were Bantu, had megaloblastic anaemia. Of the 42, 22 had typical kwashiorkor; the others had infections or were undernourished. The ages of the anaemic children ranged from 1 month to 30 months, average 14·4 months. Treatment with folic acid cured the anaemia.

Possible reasons are considered for the authors' failure to find evidence of megaloblastic anaemia in a series of patients with kwashiorkor previously studied. See Abst. 5678, Vol. 20.—F. C. Aitken.

4974

PRETORIUS, P. J., HANSEN, J. D. L., DAVEL, J. G. A. and BROCK, J. F. **Skimmed milk and kwashiorkor.** *S. African Med. J.*, 1956, **30**, 447–450. [Dept. Paediat., Univ. Pretoria.]

In trials at Pretoria and Cape Town 3 forms of skimmed milk were given to 4 groups of children with kwashiorkor. The first, given with or without a vitamin mixture to groups of 49 and 52 children, respectively, had been prepared in South Africa by roller-drying and stored in bags not impervious to moisture; the second had been spray-dried, was imported in air- and moisture-proof containers and was given to 34 children; the third was fresh with Dextrimaltose added and was tested on 41 children. The criteria were those already described (see Abst. 998, Vol. 26); the findings are tabulated with statistical analyses.

It was confirmed that skimmed milk alone is satisfactory treatment for kwashiorkor and that added vitamins do not increase its efficacy. The imported product was significantly better than the local because, it is suggested, of its better conditions of storage.—D. Harvey.

4975

THOMPSON, M. D. **Sources of protein for the prevention and treatment of kwashiorkor.** *E. African Med. J.*, 1955, **32**, 451–458. [Med. Res. Counc., Mulago Hosp., Kampala.]

WOOLLAM, D. H. M. and MILLEN, J. W. **Role of vitamins in embryonic development.** *Brit. Med. J.*, 1956, i, 1262–1265. [Dept. Anat., Univ. Cambridge.]

Animal experiments showing the importance of vitamins for the survival and development of the embryo are reviewed. If human conditions are like those in animals it can be of little avail to give extra vitamins during pregnancy. The nutrition of the embryo can be safeguarded only by attention to the diet of women throughout their lives and especially in the later stages of adolescence, so that an adequate supply of essential nutrients may be ensured from the very outset of pregnancy.—F. C. Aitken.

4978

MOORE, H. C. **Acute fatty liver of pregnancy.** *J. Obstet. Gynaecol. Brit. Empire*, 1956, **63,** 189–198. [Dept. Pathol., Rotunda Hosp., Dublin.]

Four cases of acute liver failure in pregnancy, 2 of them fatal, are described. The pathological findings from fatal cases and others recorded in the literature are discussed. The sole pathological change was fat accumulation in the liver without necrosis of liver cells. Three of the patients were treated with lipotropic substances. Two recovered but in one of them, given choline chloride intravenously, recovery was thought from the clinical assessment to be spontaneous. In the other, choline chloride and a mixture of amino acids were given intravenously.—F. C. Aitken.

Vitamin A

4980

DHANDA, R. P. **Clinical application of electroretinography with special reference to clinical manifestation of vitamin-A deficiency, cataract and glaucoma.** *Indian J. Med. Res.*, 1956, **44,** 295–303. [M.G.M. Med. Coll., Indore.]

The literature is reviewed and the principles of electroretinography are explained. Electroretinograms were recorded by the method of Karpe except that the amplifier used had a sensitivity of 1 millivolt = 1 cm. The electrical response was normal, or nearly normal, in 16 eyes of adults with different grades of xerosis. In some, xerosis had persisted for years without the development of night blindness. In one a xerotic patch had persisted for months in spite of 60 injections of vitamin A. Both the electroretinogram and the concentration of vitamin A in the blood remained normal. It is suggested that xerosis was probably not a direct manifestation of vitamin A deficiency. In a study of 60 eyes it was found that the electroretinogram was completely extinguished when the patient became night blind, and could be restored by treatment with vitamin A.

In preliminary studies on patients with cataract the electroretinogram was recorded a day before operation, and repeated on the 10th day and again 6 weeks after operation. Preliminary studies are reported also on patients with glaucoma, to test the value of electroretinography for diagnosis.

FYFE, W. M. **Vitamin-A levels in idiopathic hypercalcaemia.** *Lancet*, 1956, **270,** 610 – 612. [Royal Hosp. Sick Child., Yorkhill, Glasgow.]

Vitamin A was estimated in the plasma of 7 healthy children, 5 marasmic infants and 8 infants with idiopathic hypercalcaemia, before and 4 hr. after an oral dose of 12,500 I.U. vitamin A palmitate per kg. bodyweight. The patients with idiopathic hypercalcaemia had higher resting values, from 225 to 435, mean 275, I.U. per 100 ml. plasma, than the marasmic infants with values from 50 to 210 and the healthy children with values ranging from 70 to 205 I.U., mean 131. After the large dose had been given also, the infants with idiopathic hypercalcaemia had higher values, 905 to 3590, mean 1786 I.U., than the other children, the range being from 100 to 765 for the marasmic infants, and from 180 to 1260, mean 648, for the healthy children. Possible reasons for the abnormally high values for vitamin A in idiopathic hypercalcaemia are discussed, but it was impossible to decide from the data whether the high values were due to greater absorption or less storage.—I. M. Sharman.

4982

STEINBERG, M. D. **A new treatment for resistant warts: report of 300 cases.** *Surgery*, 1956, **39**, 642–644. [Jewish Mem. Hosp., New York.]

Treatment of warts by injection of a sterile vitamin A dispersion into the base of the verruca was successful in all except 7 out of 300 cases. The solution injected contained vitamin A palmitate 2·96 g., α-tocopherol 0·40 g., sesame oil 0·60 g., polysorbate 80 U.S.P. 10·00 g., and distilled water to 100·00 ml. Unless vitamin A was included in the solution the treatment was not successful. In about 100 cases thus treated by other physicians the results were uniformly successful.—F. C. Aitken.

Vitamin D

4983

DEAS, K. S. **Uptake of Welfare Foods: a preliminary report.** *Med. Officer*, 1956, **95**, 203–205. [Dept. Child Welfare, Edinburgh City.]

Because of the decline in uptake of Welfare Foods in Scotland, especially the vitamin supplements, for which statistics for 1952–54 are given, the vitamin D and vitamin C intakes in their 3rd and 9th months of all infants born to Edinburgh mothers between 1 July 1954 and 30 June 1955 are being investigated by health visitors; the present report is based on the first 1000 cases investigated.

Of infants in their 3rd month, 681 were said to be having national cod liver oil compound regularly, and of those in their 9th month, 671; 92 and 105, respectively, were said to be having a substitute, the most frequent being concentrated preparations of vitamins A and D. It was estimated that in the 3rd and 9th months, respectively, 691 and 350 infants were getting no vitamin D supplement or less than the amount recommended to ensure intake of the British Medical Association's standard of 800 I.U. daily. On the other hand, 470 infants in the 3rd month were being fed on national dried milk containing vitamin D and of these 366 were having a vitamin D supplement as well, some of them enough to raise the daily intake to 2000 I.U., an amount regarded by some as toxic.

The numbers said to be having national orange juice were 733 and 743, and 142 and 183 were said to be having a substitute, the most frequent being rosehip syrup and fresh orange juice. It was estimated that 468 and 637 were having no vitamin C supplement or less than the amount recommended to ensure intakes of 10 and 20 mg. ascorbic acid daily. Of infants in the 3rd month, 330 were being breast fed, and 142 were having cow's milk.

In well over half the cases where the national supplements were not given, it was stated that the babies would not or could not take them. Carelessness of mothers accounted for from 15 to 20 per cent. of omissions.—W. M. Deans.

4984

SYDOW, G. v., RANSTRÖM, S., BEREZIN, D. and AXÉN, O. **Histological findings characteristic of rickets in foetuses and young infants.** *Acta paediat.*, 1956, **45**, 114–138. [Child. Hosp., Sundsvall, Sweden.] French, German and Spanish summaries.

The material consisted of 527 infants and foetuses from hospitals at Malmö, Upsala and Sundsvall. They were arranged in weight groups: from 0 to 300 g., which included foetuses up to the 6th month, most of them obtained by legal abortion; from 310 to 1000 g., which included foetuses obtained by legal abortion and non-viable premature infants; from 1010 to 2500 g., premature infants with viable birthweight; over 2500 g., full-term infants. Histories and many details of social conditions were taken from the mother.

In sections of the costochondral junctions of the ribs, signs characteristic of rickets were common at all ages and weights, in both sexes. Those without any sign were fewer than those with. The presence of osteoid tissue was the commonest sign, and was most frequent at the lowest weights, becoming less frequent with increasing weight up to full-term, stillborn infants; among full-term infants born alive and dying in the first week of life it was again more frequent. Hypertrophic cartilage with broadening and irregularity of the costochondral junction was found in all groups also, but was less frequently present than osteoid tissue. The full histological picture of rickets was, however, rare.

In 309 instances, X-ray pictures of the left wrist were obtained after death. Most of them were normal. Abnormality was most frequent at the lowest weights. It could occur without histological signs of rickets, and it is thought that it was associated with poor development of the skeleton rather than with rickets.

On analysis of the results no evidence was obtained that shortage of vitamin D or of minerals in pregnancy had been the cause of the rachitic changes. Twins had the same histological picture.

The meaning of the results is discussed, and it is concluded that "Apparently the changes in bone structure are caused by a discrepancy between bone growth and mineralization, but the cause of this discrepancy is open to discussion".

E. M. Hume.

4985

GIRARDET, P. Hypersensibilité à la vitamine D_3? [**Hypersensitivity to vitamin D_3?**] *Helv. paediat. Acta*, 1956, **11**, 118–124. [Serv. Pédiatrie, Hôp. de la Ville, Neuchâtel.] German, English and Italian summaries.

Two cases are described in which mild signs of vitamin D excess appeared after amounts of vitamin D no greater than normal.

A boy of 4 months had 4000 I.U. vitamin D_3 daily for 2 weeks and a single dose of 600,000 I.U. about 6 weeks later. He had transitory albuminuria with casts, and the existing craniotabes was unaffected.

The second boy was aged 21 months. At 19 months he received a single dose of 600,000 I.U. vitamin D_3. His development was arrested, he had slight hydrocephalus, and transitory albuminuria with casts. He was subsequently given a single dose of 600,000 I.U. every month, in all 4 times. Each time the signs returned but disappeared again in about 3 weeks.

Neither child had a blood Ca value above the high normal. The kidney defect is regarded as a primary defect, since it could not have been caused by high blood Ca, which is usually held responsible. It is suggested that the greater activity attributed to vitamin D_3 may have contributed to the effect.—E. M. Hume.

4986

GIRARDET, P. De l'extrême tolérance à l'hypersensibilité à la vitamine D. 3. [**From extreme tolerance to hypersensitivity for vitamin D_3.**] *Pédiatrie*, 1956, **11,** 277–281. [Serv. Pédiatrie, Hôp. de la Ville, Neuchâtel.]

The author complains of the difficulty of fixing the right dose of vitamin D for treatment of human rickets. Three cases are quoted in illustration. One boy, aged 4½ years, backward and rachitic, showed slow growth and gradual healing when given 600,000 I.U. vitamin D_3 once a week for 2 years. No sign of overdosage was seen. At the other extreme are the 2 cases described in the preceding Abst.

The question is posed whether the last two cases should be regarded as the result of overdosage or of hypersensitivity. Whatever the explanation they are put forward as a warning.—E. M. Hume.

4987

SCHIAVINI, C. A. Cystinurie, cystinose et maladie de de Toni-Debré-Fanconi. [**Cystinuria, cystinosis and de Toni, Debré and Fanconi's disease.**] *Pédiatrie*, 1956, **11,** 181–203. [Osp. Maggiore, Sez. Pediat., Novara, Italy.]

The article seeks to clarify the differential diagnosis of cystinuria, cystinosis and the syndrome of de Toni, Debré and Fanconi, but it is left in doubt whether the last two, in both of which rachitic changes of the bone and low blood phosphate are present, are the same or not.

E. M. Hume.

4988

Hoo, L. K. Bijdrage tot de ziekte van Lignac-Fanconi of het syndroom van Debré-de Toni-Fanconi. [**The disease of Lignac and Fanconi or syndrome of Debré, de Toni and Fanconi.**] *Maandschr. Kindergeneesk.*, 1956, **24,** 37–48. [Kinderklin., Univ. Amsterdam.] English summary.

The case described is that of a child 6 years old, very backward, severely rachitic and with cataract. Albumin and cystine were present in the urine with an abnormally high amount of other amino acids. Crystals of cystine or tyrosine were not found in the bone marrow. The serum value for Ca was 11·5, and for inorganic P 2·1, mg. per cent. The general state improved with 50,000 "units" vitamin D daily, and drinks of Na and K citrate solution, but development was no better.

E. M. Hume.

4989

JEAN, R. Syndrome biologique évoquant celui du syndrome de de Toni-Debré-Fanconi au cours d'une intoxication par le plomb. [**Biological syndrome giving rise to that of de Toni, Debré and Fanconi in the course of lead poisoning.**] *Pédiatrie*, 1956, **11,** 263–265. [Montpellier.]

A child three years old was admitted to hospital with vomiting, weakness and signs of intracranial pressure of one week's duration. The urine contained glucose, phosphates and 12 amino acids but not cystine. Blood inorganic P was low. The condition suggested the syndrome of de Toni, Debré and Fanconi but the X-ray showed no sign of rickets. A blood test for lead showed 0·25 mg. per 100 ml. The condition gradually subsided spontaneously in hospital. It is concluded that subacute lead poisoning produced an effect on renal tubular re-absorption like that characteristic of the syndrome of de Toni, Debré and Fanconi.

4991

SEGAR, W. E., IBER, F. L. and KYLE, L. H. (with LAWSON, N. and HACKLEY, B.) **Osteomalacia of unknown etiology.** *New Engl. J. Med.*, 1956, **254,** 1011–1017. [Dept. Metabol., Div. Med., Walter Reed Army Med. Centre, Washington, D.C.]

Osteomalacia is described in a 25-year-old negro whose condition was studied in great detail. Vitamin D_2, 100,000 "units" daily, was at first without effect. After 6 weeks Ca absorption

improved, but never to an extent sufficient to heal the osteomalacia. Excretion of P in the urine was excessive and could not be attributed to renal tubular insufficiency.—D. Harvey.

Vitamin E

4992

NITOWSKY, H. M., GORDON, H. H. and TILDON, J. T. **Studies of tocopherol deficiency in infants and children. 4. The effect of alpha tocopherol on creatinuria in patients with cystic fibrosis of the pancreas and biliary atresia.** *Bull. Johns Hopkins Hosp.*, 1956, **98,** 361–371. [Dept. Paediat., Sinai Hosp., Baltimore, Md.]

For part 1 see Abst. 3633, Vol. 26.

The subjects of study were 5 boys, aged from 3 to 10½ years, with cystic fibrosis of the pancreas, and 2 male infants, aged 4½ and 9 months, with congenital biliary atresia. The extent of haemolysis of the erythrocytes by hydrogen peroxide and the values for tocopherol in the plasma and for creatine and creatinine in the urine were estimated before and after supplements of tocopherol esters were given while the patients were receiving diets low in creatine, with no meat, fish or soup which might directly affect creatine excretion. In all 7 patients tocopherol in the plasma rose when tocopherol esters were given, orally or intravenously, and the percentage of erythrocytes haemolysed fell. In one subject tocopherol in the blood rose from about 1·8 to about 7·0 mg. per 100 ml. in 22 days and percentage haemolysis fell from about 60 to 3. Creatine in the urine decreased, absolutely or in proportion to the amount of creatinine present, in all the patients with cystic fibrosis of the pancreas, but not in the infants with biliary atresia, whose excretion of creatine remained at about 30 to 35 per cent. of the total creatinine excreted. The significance of the findings is discussed in relation to the extreme muscular weakness of patients with cystic fibrosis.—I. M. Sharman.

4993

OPPENHEIMER, E. H. **Focal necrosis of striated muscle in an infant with cystic fibrosis of the pancreas and evidence of lack of absorption of fat-soluble vitamins.** *Bull. Johns Hopkins Hosp.*, 1956, **98,** 353–359. [Dept. Pathol., Sch. Med., Johns Hopkins Univ., Baltimore, Md.]

The case is reported of a male child who died at the age of 24 months with respiratory infection associated with congenital cystic fibrosis of the pancreas. The infant had no trypsin activity in the duodenal juice, but no estimation was made of tocopherol in the blood or of the amount of creatinine excreted during life, and there was no clinical proof of deficiency of vitamin E. Deficiency of other fat-soluble vitamins was shown by the anatomical lesions of rickets and by foci of squamous metaplasia in the bronchial epithelium, found at post-mortem examination performed 14 hr. after death. Photomicrographs showed that lesions in the psoas muscle resembled those in striated muscle of rabbits deprived of vitamin E. At a magnification of 100, the psoas muscle showed focal necrosis of fibres, proliferating sarcolemma nuclei and a few inflammatory cells; at a magnification of 150, loss of striae in hyaline fibres was evident.—I. M. Sharman.

Vitamin B Complex

4996

SIMPSON, I. A. and CHOW, A. Y. **The thiamine content of human milk in Malaya. 1. The "normal" level of thiamine in milk from Malay, Chinese and Indian women.** *J. Trop. Pediat.*, 1956, **2,** 3–17. [Div. Biochem., Inst. Med. Res., Kuala Lumpur, Malaya.]

The thiochrome method was used after a study, of which details are given, of its applicability and especially of the possible production of an artefact during incubation with pepsin. There were 91 samples of milk from 36 Malay, 37 Chinese and 18 Indian mothers in full lactation from the second to the seventh month or longer. Samples were collected also during early stages from 1, 24 and 10 women in the same order of race in their first week and from 6, 3 and 4 during their second to fourth weeks of lactation. None had clinical signs of vitamin B_1 deficiency or other nutritional deficiency; some had anaemia, but its origin and cause were not investigated. As far as was known no mother had extra vitamin B_1 over and above that in her diet.

The mean vitamin B_1 content during full lactation was 11·3 μg. per 100 ml.; the range was from 3·0 to 20·4, but the range of the means for different

months of lactation was narrow, from 10·2 to 11·7. Only 18 samples had values above 15, which was considered satisfactory; the values for 65 were between 6 and 15 and for 8 were less than 6. It is concluded that the intake of vitamin B_1 in Malaya is insufficient to maintain an adequate concentration in breast milk.

For the early samples a mean of 3·2 μg. per 100 ml. during the first week and of 4·8 later in the first month confirmed earlier workers' findings of a gradual increase during early lactation.

4997

KIKODZE, I. A. O vliyanii vitamina B_1 na arterial'noe davlenie. [**The influence of vitamin B_1 on arterial pressure.**] *Klin. Med., Mosk.*, 1955, **33,** No. 10, 50–53. [Propedevt. Terap. Klin., Lenin Med. Inst., Moscow.]

The subjects were 81 men and 38 women with a variety of disorders. They were divided into 2 groups, 27 with arterial pressures above 140 mm. and 92 with normal pressures. First, 14 of the first group and 5 of the second received a single intramuscular injection of 15 mg. vitamin B_1. The others received more prolonged treatment with vitamin B_1 injected into vein or muscle in different doses, an average of 20 injections of 10 or 50 mg. each.

Although in some patients arterial pressure rose, in others it fell or was unchanged, and it was not possible to ascribe any definite effect to the vitamin.

ZIELHUIS, R. L. **Enlargement of the heart to the right and nutritional deficiency.** *Doc. Med. geogr. trop.*, 1956, **8,** 179–184. [Billiton Maatschappij, Ltd., Indonesia.]

The incidence of right-sided enlargement of the heart was estimated by percussion in groups of Indonesian and Chinese labourers and their families in the Riau Archipelago. Enlargement was present in all the groups but was more frequent in the Indonesians than the Chinese; it was frequently found in several members of the same family. The basic ration given to the labourers was of polished rice and the incidence of enlargement varied inversely with the intake of supplementary foods supplying vitamin B_1. Classical signs of vitamin B_1 deficiency were frequent, and it was considered probable that the enlargement of the heart was a sign of the same deficiency.

BAUER, H. Die Brenztraubensäurekonzentration im Blut von multiplen Sklerosen und Kontrollfällen. Vergleichende Studien zur Methodik und klinischen Bedeutung der Brenztraubensäurebestimmung im Blut. [**Pyruvic acid in blood in patients with multiple sclerosis and control subjects. Comparative studies of the technique and clinical significance of estimation of pyruvic acid in the blood.**] *Biochem. Ztschr.*, 1956, **327,** 491–501. [Neurol. Klin., Univ. Hamburg, Eppendorf.] English summary.

A chromatographic method with dinitrophenylhydrazine and lactic acid dehydrogenase was used to estimate pyruvic acid in venous blood deproteinised with trichloroacetic acid. It was shown first that stasis of the blood and muscular exercise raised both pyruvic acid and lactic acid in blood to twice the resting value in free-flowing blood. There was no difference in pyruvic and lactic acid mean values and range between 33 patients with multiple sclerosis, per cent., pyruvic 0·55 mg. (0·23 to 0·82), lactic 7·5 mg. (4·1 to 13·9) and 42 healthy subjects, pyruvic 0·53 mg. (0·30 to 0·81) and lactic 8·1 mg. (5·4 to 11·0), a result which contradicts earlier reports. Nor was pyruvic acid higher in acute than in chronic sclerosis; indeed, the difference was the other way round and is attributed to the spasticity of muscle.

Vitamin B_1 phosphate, 100 to 250 mg., or vitamin B_1 pyrophosphate, 100 to 150 mg., was given by intravenous injection to healthy volunteers; there was no change in the blood sugar value but in 4 out of 5 tests blood pyruvic acid fell abruptly though never to a value below the lower limit of normal.

In comparison with the modification of the method used here to include an enzyme, the more usual form of the dinitrophenylhydrazine method gave values 30 to 40 per cent. higher, a difference which is ascribed to non-specific reaction with the reagent of other acids, particularly acetic and α-ketoglutaric.—I. Leitch.

5000

REYMOND, C., WILD, C., BÉRAUD, T. and VANNOTTI, A. Cocarboxylase et sclérose en plaques. [**Cocarboxylase and multiple sclerosis.**] *Schweiz. med. Wochenschr.*, 1956, **86,** 328–331. [Clin. Méd., Univ. Lausanne.]

Estimation of blood cocarboxylase by the method of Westenbrink and Stein-Parvé (see Title 330, Vol. 20), showed lower values for 15 patients with multiple sclerosis than for 36 normal subjects. Fasting values for lactate and pyruvate in the blood were similar in patients and normal subjects, but after intravenous injection of fructose both values rose higher in patients, and returned more slowly to normal. It is suggested that the disturbances of carbohydrate metabolism might be related to failure of phosphorylation of vitamin B_1 in multiple sclerosis and that treatment with cocarboxylase might be helpful.

GOLDSMITH, G. A., GIBBENS, J., UNGLAUB, W. G. and MILLER, O. N. **Studies of niacin requirement in man. 3. Comparative effects of diets containing lime-treated and untreated corn in the production of experimental pellagra.** *Amer. J. Clin. Nutrition*, 1956, **4**, 151–160. [Div. Nutrit. Metabol., Dept. Med., Sch. Med., Tulane Univ., New Orleans, La.]

For part 2 see Abst. 1043, Vol. 26.

Pellagra was produced in 4 women in repeated trials with a diet containing from 15 to 20 per cent. of unmilled maize from Guatemala; the maize was treated with lime in the traditional manner or was untreated. The respective nicotinic acid contents of the diets were 16 and 17·4 μg. per g. dry weight. As judged by the time when signs appeared, or by the daily urinary excretion of nicotinic acid metabolites while the deficient diet was being eaten or after more nicotinic acid and tryptophan had been given, treatment with lime had no effect on the pellagra-producing properties of the maize. In a previous study (Abst. 856, Vol. 23) pellagra was produced in 3 subjects by a diet containing unenriched milled maize from the United States with amounts of nicotinic acid and tryptophan similar to those in the Guatemalan diets, but signs appeared later with the United States maize than with the Guatemalan maize. Though deficiency of nicotinic acid and tryptophan may be of prime importance in the production of pellagra by maize diets, the findings in the present work support the view that other substances, possibly in the germ or bran, may operate also.

BESSEY, O. A., HORWITT, M. K. and LOVE, R. H. **Dietary deprivation of riboflavin and blood riboflavin levels in man.** *J. Nutrition*, 1956, **58**, 367–383. [Dept. Biochem. Nutrit., Univ. Texas Med. Branch, Galveston.]

Riboflavin, flavin mononucleotide and flavin dinucleotide were estimated fluorimetrically in red cells, white cells and blood plasma from men whose intake of riboflavin over long periods was known. For 10 men restricted to an intake of 0·55 mg. daily for 16 months the riboflavin content per 100 ml. red cells was from 10·0 to 13·1 μg. compared with from 20·2 to 27·6 μg. for 6 men taking from 2·55 to 3·55 mg. daily. Free riboflavin and mononucleotide in the plasma were generally less in men with restricted intake of riboflavin, but the values for dinucleotide in the plasma and for total riboflavin in the white cells were little changed. In another group of men riboflavin in the red cells was measured at intervals for 9 months on a diet containing only 0·5 mg. daily. Within 45 days there was a significant decrease, which progressed throughout the period of restriction. It was concluded that the riboflavin content of the red blood cells is a useful index to the state of riboflavin nutrition.

SCHAUS, R. and KIRK, J. E. **The riboflavin concentration of brain, heart, and skeletal muscle in individuals of various ages.** *J. Gerontol.*, 1956, **11**, 147–150. [Div. Gerontol., Sch. Med., Washington Univ., St. Louis.]

Riboflavin was estimated fluorimetrically by the method of Bessey *et al.* (Abst. 3377, Vol. 19) in

tissues obtained at autopsy. Results are tabulated for 89 samples of cerebral cortex, 86 of heart and 88 of pectoral muscle from persons aged from 7 days to 92 years. The average concentration of riboflavin in μg. per g. wet tissue was 2·72 in brain, 12·38 in heart and 2·48 in skeletal muscle. No correlation between concentration and age was obtained except for a decrease of riboflavin in heart tissue in subjects over 80 years of age.

HIRASHIMA, H. **[Studies on angular stomatitis in Tokushima prefecture. 2. Angular stomatitis in schoolchildren and middle-school students.]** *Shikoku Acta med.*, 1955, **7,** No. 6, 7–11. In Japanese: English summary. [Dept. Paediat., Sch. Med., Tokushima Univ.]

For part 1 see Abst. 3653, Vol. 26.

In the years 1952 to 1954 children numbering 17,152 were examined, 50 boys and 51 girls in kindergartens, 7237 boys and 6895 girls in elementary schools and 1499 boys and 1420 girls in middle schools. Angular stomatitis was commoner in boys than girls, the percentage incidence for the groups in the above order being 10·0, 18·9 and 19·1 for boys and 5·9, 9·9 and 9·4 for girls. Except for the small numbers in kindergartens the children were grouped also according to place of abode. For those in elementary schools of whom 2797 were in towns and 7419, 2488 and 1428 in villages described, respectively, as agricultural, mountain and fishing, the percentage incidence was 5·0, 17·1, 17·8 and 13·9. For the middle-school populations, 1623, 676 and 620, respectively, in agricultural, mountain and fishing villages, the incidence was 12·4, 20·0 and 13·5 per cent. The data are tabulated with headings in English. (From summary.)

WRIGHT, L. D., CRESSON, E. L. and DRISCOLL, C. A. **Biotin derivatives in human urine.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 248–252. [Res. Labs., Sharp and Dohme, Div. Merck and Co., West Point, Pa.]

Free biotin in 4 samples of human urine was estimated with *Lactobacillus arabinosus* and total biotin with *Neurospora crassa*. Direct microbiological methods and bio-autographic procedures were used. There were relatively large amounts of free biotin in all samples and very small additional amounts of biotin that could be measured with *Neurospora crassa*. Chromatographic studies suggested that the substance additional to free biotin might be " biocytin sulphoxide ". All the biotin in urine was capable of being combined with avidin. The results are discussed with reference to reports by other workers of unusual biotin derivatives in urine.—A. M. Copping.

HARRIS, J. W., WHITTINGTON, R. M., WEISMAN, R. (Jr.) and HORRIGAN, D. L. **Pyridoxine responsive anemia in the human adult.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 427–432. [Dept. Med., Cleveland City Hosp., Ohio.]

A man of 27 had severe hypochromic anaemia without disturbances of the skin, tongue or nervous system. He had an adequate diet providing about 3 mg. pyridoxine daily. His signs and symptoms were abolished by transfusions and there was a spontaneous remission lasting 5 years and then a relapse. No haemolysin or agglutinin was found and red cell fragility was normal, but red cell survival time was low. There was no response to different liver extracts given by intramuscular injection or by mouth, to brewer's yeast, ferrous sulphate, Co, folic acid, ascorbic acid, leucovorin, cyanocobalamin, pantothenic acid, cortisone, human plasma, or a preparation containing vitamins A, D, B_1, ascorbic acid, riboflavin and nicotinic acid, but the Hb level was maintained by repeated transfusion of whole blood. Pyridoxine hydrochloride, 200 mg. by intramuscular injection daily, produced rapid subjective improvement, a reticulocyte peak of 50·8 per cent. and a rapid rise in Hb and haematocrit. When pyridoxine was withdrawn there was another relapse, but resumption of treatment with 10 mg. pyridoxine daily was successful. Tryptophan metabolism was abnormal, as shown by the abnormal metabolites in the urine.—D. Duncan.

5013

WEIDEMANN, J. Über zentrale psychophysiologische Veränderungen nach oralen Folsäuregaben. [**Central psychophysiological changes after oral administration of folic acid.**] *Arch. Psychiat. Nervenkrankh.*, 1955, **193**, 383–390. [Klin. Berufserkrankungen Kloster Grafschaft, Hochsauerland.]

To test the possible effect of folic acid on the central nervous system, a daily dose of a preparation of the vitamin B complex devoid of folic acid, or of 1·2 mg. folic acid was given for 19 days to 2 groups each of 10 healthy young men. Critical flicker fusion frequency was measured throughout the test and for a week afterwards. The preparation of vitamin B complex produced a small but constant decrease in the critical frequency which persisted during the week after treatment, but folic acid produced a marked and significant increase in the frequency, which showed 2 peaks, one on the third day of treatment and the other in the week after treatment. The significance of the results is discussed.—L. Wills.

5014

SILVERMAN, M. and GARDINER, R. C. **Labile citrovorum factor in urine.** *J. Bacteriol.*, 1956, **71**, 433–438. [Nat. Inst. Arthritis Metabol. Dis., Nat. Insts. Health, Bethesda, Md.]

Urine from human subjects from 3 to 5 hr. after they had taken 5 or 15 mg. folic acid by mouth contained a growth factor for *Leuconostoc citrovorum*. It was rapidly destroyed in samples stored at room temperature or autoclaved, but not if ascorbic acid was added. Chromatographic studies showed that the labile compound was a reduced N^{10} formylfolic acid derivative. The implications of the findings are discussed with reference to studies of the identity of citrovorum factor from liver, from *Streptococcus faecalis* and from urine.—A. M. Copping.

5015

CRAIGMILE, D. A., PRESTON, J. E. and BERRY, W. T. C. **Similarity of growth and health in day nursery children with and without vitamin B_{12} supplements.** *Monthly Bull. Minist. Health and Pub. Health Lab. Serv.*, 1956, **15**, 78–79. [Dept. Pub. Health, Birmingham.]

The gains in height and weight of 22 nursery schoolchildren given 50 μg. vitamin B_{12} each day of attendance for 6 months were not significantly different from those of a group of 25 children given dummy doses. The average time of absence due to colds and measles was about the same in the 2 groups. Previous administration of vitamin B_{12} apparently did not hasten recovery.

GIRDWOOD, R. H. **The megaloblastic anaemias: their investigation and classification.** *Quart. J. Med.*, 1956, **25**, 87–119. [Dept. Med., Univ. Edinburgh.]

Over 1000 patients with megaloblastic anaemia were examined, in India, Burma, Great Britain and the United States. In many, vitamin B_{12} in the serum was estimated with *Lactobacillus leichmannii*, and folic acid output in the urine was studied after test doses given by mouth and subcutaneously. Illustrative histories of 15 patients are given.

Estimation of vitamin B_{12} in the serum is considered especially valuable for early diagnosis of Addisonian anaemia and anaemia after gastrectomy. Nutritional anaemias need more investigation by modern methods. Tropical megaloblastic anaemia of pregnancy is considered to be probably the same as nutritional megaloblastic anaemia. The form occurring in Britain is associated with a normal serum value for vitamin B_{12} and normal absorption of folic acid, and interference with folic acid metabolism is postulated as the cause. Reasons for failure of some patients to respond to treatment are discussed.—D. Duncan.

5017

VINKE, B. and VAN DER SAR, A. **Megaloblastic nutritional anaemia in Curaçao.** *Doc. Med. geogr. trop.*, 1956, **8**, 151–163. [Dept. Int. Med., Pub. Health Serv., Netherlands Antilles.]

Megaloblastic anaemia, confirmed by sternal puncture, was found in 16 negroid women, 1 negroid man and 1 European. Pernicious anaemia and sprue were excluded by examination of stomach contents and stool, the clinical history and the results of treatment. Signs of subacute combined degeneration of the cord were absent in all the patients. The basis of the diet was maize; few vegetables were eaten. All the patients were undernourished. The results of therapeutic trials with iron, Marmite and folic acid given by mouth and with vitamin B_{12} and citrovorum factor given parenterally showed that most of the patients lacked iron, 17 were deficient in vitamin B_{12} and 1 had a simple deficiency of folic acid. Deficiency of vitamin B_{12} and folic acid was present in 3 patients and probably also in another 5. Analysis of the serum of 2 patients showed low values for vitamin B_{12} and folic acid. The influence of diet and of the body's stores of vitamin B_{12} and folic acid on the development of megaloblastic anaemia is discussed.—L. Wills.

5018

HARRISON, R. J., BOOTH, C. C. and MOLLIN, D. L. **Vitamin B_{12} deficiency due to defective diet.**

Lancet, 1956, **270**, 727–728. [St. James' Hosp., London.]

A woman of 77 with megaloblastic anaemia had a low value for vitamin B_{12} in the serum and the anaemia responded when vitamin B_{12} was given by intramuscular injection. Despite a gastro-enterostomy made 35 years previously, fat balance was normal, and so was absorption of radio-active vitamin B_{12} given by mouth. The findings of gastric biopsy were not consistent with a diagnosis of Addisonian pernicious anaemia. For the past 10 years the woman had lived on a diet of bread and margarine, tea with a little milk, and potatoes. Vitamin B_{12} intake, from the milk, was estimated to be 0·4 μg. daily. It was concluded that the case was one of dietary deficiency.—F. C. Aitken.

DHOPESHWARKAR, G. A., TRIVEDI, J. C., KULKARNI, B. S., SATOSKAR, R. S. and LEWIS, R. A. **The effect of vegetarianism and antibiotics upon proteins and vitamin B_{12} in the blood.** *Brit. J. Nutrition*, 1956, **10**, 105–110. [Pharmacol. Res. Unit, C.S.I.R., Seth G.S. Med. Coll., Bombay.]

The volume of packed red cells and the content of albumin and of α- and β-globulin were measured in the blood of 5 vegetarian and 5 non-vegetarian students. The vegetarians took milk but no other animal protein. Albumin values were low and globulin high compared with those of the non-vegetarians. No difference was found between haematocrit values, but the vitamin B_{12} content of the blood was 12 mμg. per 100 ml. in the vegetarians and 41 in the non-vegetarians. Aureomycin, 50 mg. daily for 2 months, raised the albumin, reduced the globulin, and significantly increased the vitamin B_{12}, in the plasma of the vegetarians.—A. M. Copping.

ROSENBLUM, C., YAMAMATO, R. S., WOOD, R., WOODBURY, D. T., OKUDA, K. and CHOW, B. F. **Comparative absorption of vitamin B_{12} analogues by normal humans. 2. Chloro-, sulfato-, nitro- and thiocyanato- *vs* cyanocobalamin.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91**, 364–367. [Merck, Sharp and Dohme Res. Labs., Rahway, N.J.]

It was confirmed that the rate of absorption of cyanocobalamin was greater than that of chlorocobalamin, as reported previously (Abst. 1068, Vol. 26). It had been found also that sulphato-, nitro-, thiocyanato- and nitro-cobalamin derivatives were less well absorbed than cyanocobalamin by both man and the rat. In the present experiments excretion was measured in the urine and faeces of human subjects and in the faeces of rats. The amount of vitamin B_{12} or its analogue was measured in the serum of some subjects and the results confirmed those of the excretion tests.

MACLEAN, L. D. and SUNDBERG, R. D. **Incidence of megaloblastic anemia after total gastrectomy.** *New Engl. J. Med.*, 1956, **254**, 885–893. [Dept. Surg., Med. Sch., Univ. Minnesota, Minneapolis.]

Of 13 patients shown by microscopic examination of the tissue removed at operation to have undergone complete gastrectomy, who survived for 3 years or longer, and for whom all the necessary information was available, megaloblastic anaemia indistinguishable from pernicious anaemia developed in from 2 years 8 months to 7 years 5 months in 10; 2 patients received prophylactic treatment and remained well, and the remaining patient examined after 2 years and 5 months did not then show any macrocytosis. In 4 patients at another hospital megaloblastic anaemia developed 3 or more years after total gastrectomy. The condition for which the operation was performed and the mode of reconstruction of the intestinal canal varied. In the whole series 5 of the patients had free HCl in the gastric juice before operation. All responded to parenteral vitamin B_{12}. The results and the literature are discussed and it is concluded that production of intrinsic factor is the only indispensable activity of the stomach in man.—L. Wills.

5023

BADENOCH, J., EVANS, J. R., RICHARDS, W. C. D. and WITTS, L. J. **Megaloblastic anaemia following partial gastrectomy and gastro-enterostomy.** *Brit. J. Haematol.*, 1955, **1**, 339–344. [Nuffield Dept. Clin. Med., Radcliffe Infirmary, Oxford.]

Five patients developed megaloblastic anaemia from 2 to 12 years after partial gastrectomy and one 17 years after gastro-jejunostomy. None had a family history of pernicious anaemia. All excreted subnormal amounts of uropepsinogen, and none had free HCl in the gastric juice, though 4 out of 5 were known to have had it before operation. In 5 of the 6 patients, gastric biopsy material showed severe or moderate atrophy of the glands, though in material removed at operation normal gastric-body glands were present; these 5 patients responded to treatment with vitamin B_{12}. Three patients had mild steatorrhoea, but

in the others the absorption of fat was nearly normal and the steatorrhoea was not considered of etiological importance. In 2 patients the serum vitamin B_{12} concentration was like that in pernicious anaemia, but in the others it was within normal limits. In all the patients the absorption of vitamin B_{12} was low, but was increased by the addition of intrinsic factor to the test dose. In the patient with no gastric atrophy, however, the absorption of the vitamin without addition of intrinsic factor was greater than is usual in pernicious anaemia and the etiology of that case remains obscure.—L. Wills.

5024

GARDNER, F. H. **Observations on the cytology of gastric epithelium in tropical sprue.** *J. Lab. Clin. Med.*, 1956, **47,** 529–539. [Trop. Res. Med. Lab., U.S. Army, San Juan, Puerto Rico.]

Samples of mucosal cells were obtained from the stomach with a rotating brush inserted through the mouth. Nineteen patients with untreated sprue and 22 without gastro-intestinal disease were studied. Abnormalities of squamous and columnar cells resembling those seen in pernicious anaemia were found in the patients with sprue. In 16 patients with sprue treated with folic acid or vitamin B_{12} the macrocytic anaemia disappeared after one month or longer; abnormal squamous cells disappeared after 3 months of treatment in all except 3 patients, but abnormal columnar cells persisted.—F. C. Aitken.

5025

BASTRUP-MADSEN, P. **Granulopoietic maturation disturbances as a sign of incipient pernicious anaemia. Illustrated by the clinical course in three cases.** *Acta med. scand.*, 1956, **154,** 325–332. [Dept. Med., Amtssygehus, Aarhus.]

In 3 patients with clinical signs and symptoms suggesting pernicious anaemia the diagnosis was at first rejected because the anaemia was mild and red cell formation in the bone marrow was normal. All 3 showed some abnormality in maturation of neutrophilic granulocytes. All 3 subsequently developed the neurological picture of true pernicious anaemia, and one after 8 years had typical megaloblastic anaemia. The importance of apparently slight changes in the bone marrow for early diagnosis of pernicious anaemia is suggested.

ESTREN, S. and WASSERMAN, L. R. **Pernicious anemia. 1. Remission by small oral doses of purified vitamin B_{12}.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 499–503. [Dept. Haematol., Mount Sinai Hosp., New York.]

In 11 trials on 8 patients with pernicious anaemia in relapse, complete or partial remission followed the oral administration of purified, crystalline vitamin B_{12} in daily doses ranging from 5 to 16·8 μg. When treatment was stopped the remissions tended to be brief. Certain patients failed to respond a second time and 3 other patients failed to respond at all to the same oral doses. The findings, in the authors' opinion, support the view that the changes in gastric secretion in pernicious anaemia are quantitative rather than qualitative.

L. Wills.

5027

BRIGEAU, J., LAMBIN, S. and GERMAN, A. Sur la résorption de la vitamine B_{12} administrée par voie rectale. [**Absorption of vitamin B_{12} given by rectum.**] *C.R. Soc. Biol.*, 1956, **150,** 78–82.

Administration to human subjects of 1000 μg. vitamin B_{12} daily for from 5 to 7 days in a rectal suppository caused a rise in the vitamin B_{12} content of the blood as estimated with *Bacterium coli*. Small doses by rectum had no significant effect. Absorption appeared to be improved in 2 subjects when intrinsic factor or folic acid was given with vitamin B_{12}.—A. M. Copping.

5028

BAST, G. Beitrag zur Therapie der perniziösen Anämie mit oralen Kombinationspräparaten. [**Treatment of pernicious anaemia with combined oral preparations.**] *Ztschr. ges. inn. Med.*, 1956, **11,** 241–247. [Med. Klin., Univ. Rostock.]

For 22 patients, 2 oral preparations, Bifacton and Pylovit, each containing vitamin B_{12} and a preparation of intrinsic factor, were as effective as vitamin B_{12} given parenterally for treatment of decompensated pernicious anaemia in daily amounts containing from 15 to 50 μg. vitamin B_{12}. The effectiveness of the preparations for maintenance and treatment of subacute combined degeneration of the cord could not be judged as the periods of observation were too short.—L. Wills.

5029

BAKER, H., SOBOTKA, H., PASHER, I. and HUTNER, S. H. **Comparative study of vitamin B_{12} assay in urine.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 636–638. [Dept. Chem., Mount Sinai Hosp., New York.]

The vitamin B_{12} content of human urine was measured with *Ochromonas malhamensis*, *Euglena gracilis* and *Lactobacillus leichmannii*. In tests for recovery of vitamin B_{12} added to urine, satisfactory results were obtained with *Ochromonas* and *Euglena*. True vitamin B_{12} appeared to be measured by *Ochromonas*; higher results were obtained with *Euglena* and *L. leichmannii*, which responded to other members of the vitamin B_{12} group or to

other metabolites. Total output of vitamin B_{12} in 8 hr. after a dose of 50 μg. ranged from 0·6 to 28·7 μg. in 23 subjects. From the results of estimations by the 3 organisms amounts of interfering substances in urine could be estimated.

RABINER, S. F., LICHTMAN, H. C., MESSITE, J., WATSON, R. J., GINSBERG, V., ELLENBOGEN, L. and WILLIAMS, W. L. **The urinary excretion test in the diagnosis of Addisonian pernicious anaemia.** *Ann. Int. Med.*, 1956, **44,** 437–445. [Dept. Med., State Univ. New York Coll. Med., Brooklyn.] Interlingua summary.

A modification of Schilling's test was used in which the parenteral flushing dose of non-radioactive vitamin B_{12} was given on 2 successive days and the total urinary excretion of radio-activity during that period was estimated. The mean total excretion for 24 normal subjects was 13·3 with range 5·0 to 34·2 per cent. of the test dose of 2·0 μg. vitamin B_{12} ^{60}Co, and for 36 patients diagnosed as suffering from pernicious anaemia 0·85, with range 0·5 to 3·0 per cent. After the addition of intrinsic factor to the test dose the mean excretion for the 33 patients re-tested was 8·2 with range 1·8 to 19·2 per cent. Of the 33 patients, 26 had values within normal limits, 5 showed values above the upper limit for pernicious anaemia patients given the vitamin alone, but below the lower limit for normal subjects, and 2 patients continued to show very low rates of excretion. For the diagnosis to be one of true pernicious anaemia it is concluded that not only must the initial excretion of radio-activity after the test dose be outside the normal limits, but also it must be significantly raised when adequate amounts of a potent preparation of intrinsic factor are added to the test dose of vitamin B_{12} ^{60}Co.—L. Wills.

5031

BAKER, S. J. and MOLLIN, D. L. **The relationship between intrinsic factor and the intestinal absorption of vitamin B_{12}.** *Brit. J. Haematol.*, 1955, **1,** 46–51. [Dept. Pathol. Haematol., Postgrad. Med. Sch., Ducane Rd., London, W.12.]

Absorption of vitamin B_{12} was measured from the radio-activity of the faeces after a test dose of ^{58}Co-vitamin B_{12} in patients with pernicious anaemia in remission. Over a certain range of dosage there was a straight line relationship between the amount of vitamin B_{12} absorbed and the amount of intrinsic factor given; the slope of the line was termed the vitamin B_{12} absorption gradient. The gradient varied greatly from patient to patient and in some was flat, suggesting that absorption was poor and that oral treatment would not be effective. Beyond a certain level of dosage, which differed in different patients, further increase in the amount of intrinsic factor given did not increase absorption of vitamin B_{12}. If the amount of vitamin B_{12} given was varied and the dose of intrinsic factor was kept constant the total amount of vitamin absorbed remained the same. Very large intramuscular doses of vitamin B_{12} inhibited absorption of the vitamin given orally.—L. Wills.

5032

REISNER, E. H. (Jr.), GILBERT, J. P., ROSENBLUM, C. and MORGAN, M. C. **Applications of the urinary tracer test (of Schilling) as an index of vitamin B_{12} absorption.** *Amer. J. Clin. Nutrition*, 1956, **4,** 134–141. [Dept. Med., St. Luke's Hosp., New York.]

Absorption of vitamin B_{12} was estimated by Schilling's method after a standard oral dose of 2 μg. vitamin B_{12} ^{60}Co with a specific activity of 200 μC. per mg.

In 27 patients with pernicious anaemia the mean urinary excretion was 0·5 per cent. of the test dose; the addition of from 42 to 62 ml. of normal gastric juice increased the excretion to from 4·1 to 12·8 per cent. Trials with preparations of intrinsic factor in different doses showed that a net excretion of 2·5 per cent. or more of the test dose after the addition of intrinsic factor was generally a sign that the best clinical effect would be produced by that preparation given in the same dose.

In 13 patients with sprue the mean excretion was 1·1 per cent. of the test dose; the addition of a potent preparation of intrinsic factor to the test dose did not increase absorption in 9 of these patients or in another 7 with megaloblastic anaemia with achlorhydria, of whom 5 were from the tropics and had been diagnosed as having pernicious anaemia but who, as the result of the test, were considered to have some other condition.

5033

CHOW, B. F., GILBERT, J. P., OKUDA, K. and ROSENBLUM, C. **The urinary excretion test for absorption of vitamin B_{12}. 1. Reproducibility of results and agewise variation.**

CHOW, B. F., WILLIAMS, W. L., OKUDA, K. and GRASBECK, R. **2. Effect of crude and purified intrinsic factor preparation.** *Amer. J. Clin. Nutrition*, 1956, **4,** 142–146; 147–150. [Dept. Biochem., Sch. Hyg. Pub. Health, Johns Hopkins Univ., Baltimore, Md.]

1. Absorption of vitamin B_{12} was studied in 40 normal men aged from 19 to 85 years by Schilling's urinary excretion test and by microbiological tests. Most of the vitamin B_{12} ^{60}Co, given by mouth, was excreted during the second half of the day and the mean 24-hr. excretion was

11·4 per cent. of the test dose; a microbiological test showed that most of the injected non-active vitamin B_{12} was excreted during the first 12 hr. and that excretion was almost complete in 24 hr. There was no significant difference in the excretion of vitamin B_{12} ^{60}Co between age groups, and repeat tests on 8 subjects aged from 20 to 26 years were reproducible within from 10 to 15 per cent. of the first value. Repeat tests on 8 older subjects showed greater variability but no significant increase in excretion after the addition of intrinsic factor to the test dose. In a few of the older subjects little of the radio-active vitamin was excreted.

2. Three preparations of intrinsic factor were tested on some of the younger subjects; 2 had potencies such that 25 and 50 mg., each with 15 μg. vitamin B_{12} ^{60}Co, equalled 1 U.S.P. unit, and one highly purified preparation had a potency such that 1 mg. with the same dose of the vitamin equalled 1 U.S.P. unit. Extensive trials showed that, after a dose of 2·0 μg. vitamin B_{12} ^{60}Co alone, urinary excretion in 24 hr. ranged from 204 to 240 mμg., and after 50 μg. from 442 to 491 mμg. One of the 2 crude intrinsic factor preparations in amounts equivalent to 4 U.S.P. units given with 50 μg. of the vitamin produced a statistically significant decrease in excretion to a value below the lower limit of excretion after the vitamin alone, but the addition of an equivalent amount of the purified extract produced a significant rise in excretion. Smaller doses of the crude extracts had no inhibitory effect on absorption after oral administration. The purified extract when tested by the microbiological or the dialysis method was shown to bind vitamin B_{12}. It is concluded that the binding property of the crude extracts was caused by an extraneous factor and not by the intrinsic factor itself.—L. Wills.

BEST, W. R., WHITE, W. F., ROBBINS, K. C., LANDMANN, W. A. and STEELMAN, S. L. **Studies on urinary excretion of vitamin B_{12} Co^{60} in pernicious anemia for determining effective dosage of intrinsic factor concentrates.**

BEST, W. R., LANDMANN, W. A. and LIMARZI, L. R. **Time pattern of vitamin B_{12} Co^{60} urinary excretion in man after oral administration and parenteral "flushing".** *Blood, J. Hematol.*, 1956, **11,** 338–351; 352–356. [Dept. Med., Univ. Illinois Coll. Med., Chicago.] Interlingua summary.

(a) Schilling's urinary excretion test was made on patients with pernicious anaemia given 2·0 or 15·0 μg. vitamin B_{12} ^{60}Co with or without concentrates of intrinsic factor in doses of from 10 to 1600 mg. With both doses of the vitamin, excretion of radio-activity increased with intrinsic factor in small amounts, but showed little increase with moderate amounts and frequently a decrease with large amounts; excretion of the vitamin with both doses appeared to be linearly related to the logarithm of the dose of intrinsic factor. Thirteen of the patients who were in relapse were given one or other of the doses of vitamin B_{12} ^{60}Co with different amounts of the intrinsic factor under test and progress was assessed haematologically. At the end of each clinical trial urinary excretion was tested with the dose of vitamin and intrinsic factor used in that trial. The results of clinical trials and excretion tests showed fair correlation. The values for excretion of vitamin B_{12} ^{60}Co in the urine suggested that a mean between 500 and 550 mμg. per 24 hr. indicated a degree of absorption that would produce a remission in most cases. Techniques are discussed.

(b) Repeated serial estimations of the urinary output of radio-activity during the 28 hr. after an oral test dose of 2·0 μg. vitamin B_{12} ^{60}Co followed in 2 hr. by a parenteral flushing dose of 1000 μg. non-radio-active vitamin B_{12} were made on 5 control subjects, and 10 patients with pernicious anaemia to whom the oral test dose was given alone or with a potent preparation of intrinsic factor. In all the tests there was little difference in the time pattern of excretion even when no intrinsic factor was given and the amount of radio-activity excreted was very small. In the 4 hr. after the oral dose little radio-activity was excreted in the urine; excretion then rose to a peak or peaks between the sixth and twelfth hours and then fell to a low level. Almost all the radio-activity was excreted in the first 24 hr.—L. Wills.

5035

ELLENBOGEN, L. and WILLIAMS, W. L. **Improved urinary excretion test for assay of intrinsic factor. 2. Sensitive counting technic.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 617–619. [Nutrit. Physiol. Sect., Res. Div., Amer. Cyanamid Co., Lederle Labs., Pearl River, N.Y.]

A modification of the method of measuring radio-activity in the urine of human subjects given vitamin B_{12} containing ^{60}Co (Abst. 1073, Vol. 26) introduced a beaker fitting into the well of a scintillation counter. Large volumes of urine with a low count could be examined, and so smaller doses of radio-active vitamin B_{12} could be given in successive tests on the same patient.

GLASS, G. B. J., GOLDBLOOM, A. A., BOYD, L. J., LAUGHTON, R., ROSEN, S. and RICH, M. **Intestinal absorption and hepatic uptake of radioactive vitamin B_{12} in various age groups**

and the effect of intrinsic factor preparations. *Amer. J. Clin. Nutrition*, 1956, **4**, 124–133. [Dept. Med., New York Med. Coll.]

Absorption of vitamin B_{12} from the intestine was estimated by measurement of uptake in the liver after a dose of 0·5 μg. vitamin B_{12} ^{60}Co with or without intrinsic factor; the counts of radio-activity were made on the sixth and seventh days after the test dose. The method used is described. Tests were made with 60 subjects aged from 18 to 90 years, and free from anaemia and organic disease of the digestive tract or liver. Gastric acidity was estimated in 41 of them. A scatter diagram of the values for radio-activity in the liver showed no obvious decrease with advancing age and in all age groups the range of values was wide. The range was greater in subjects with normal acidity than with hypo- or anacidity, and in 30 subjects over the age of 60 years the counts were significantly lower in those with defective acidity than in those with normal acidity. There was a significant increase of uptake in the liver when intrinsic factor was given with vitamin B_{12} in 20 of 44 subjects; of these 10 out of 14 tested had hypo- or anacidity.—L. Wills.

5037

Milevskaya, Yu. L. Soderzhanie vitamina B_{12} v krovi u bolnykh pernitzioznoi anemiei. **[Concentration of vitamin B_{12} in the blood of patients with pernicious anaemia.]** *Klin. Med., Mosk.*, 1955, **33**, No. 12, 53–58. [Moscow.]

Twenty patients were studied, 18 with pernicious anaemia, 1 with chronic enterocolitis with anaemia of the type found in European sprue, and 1 with anaemia after resection of the small intestine. All had severe anaemia with Hb from 13 to 35 or 40 per cent. [standard not quoted] and erythrocytes from 840,000 to 2,000,000. All were treated with vitamin B_{12} only, except one with Hb 13 per cent. and erythrocytes 840,000 who required transfusion. Haematological tests of bone marrow were made on 12 patients before and 24 and 28 hr. after treatment, 4 with 15 μg. and 8 with 30 μg. vitamin B_{12}. In all, blood formation changed from megaloblastic to normoblastic, and in peripheral blood reticulocytes were between 6 and 35·6 per cent., in one case 53 per cent. The speed and completeness of remission were not strictly related to dosage; on the average, the amount of vitamin B_{12} required to raise the erythrocyte count to 4 or 4·5 million was from 30 to 120 μg. Hb and erythrocyte values in a given patient reached a maximum which was not exceeded when more vitamin B_{12} was given. In most patients remission occurred after from 18 to 28 days. They were not treated after discharge and, within the first year, 3 patients relapsed after 6 or 7 months and returned for further treatment.

Vitamin B_{12} in large doses, 240 μg. in the case described, was found beneficial also in subacute combined degeneration.

In blood from 5 healthy persons concentrations of vitamin B_{12} ranged from 0·6 to 1·15 mμg. per 100 ml., which is in fair agreement with values obtained by other investigators. Patients with severe megaloblastic anaemia and Hb from 13 to 35 per cent. had concentrations below 0·008 mμg. per ml. Vitamin B_{12}, 15 μg. by injection, raised the concentration to normal or above within from 3 to 6 hr., but the rise was not maintained. There was considerable individual variation in response to the same amount of vitamin B_{12}.

In Fe-deficiency anaemia vitamin B_{12} was said to improve the utilisation of Fe.—F. Billewicz.

Karlin, R. and Dumont, M. Sur le taux de vitamine B_{12} dans le sérum sanguin chez la femme au cours de l'accouchement, dans celui du cordon et dans le placenta. **[Vitamin B_{12} in the blood serum of women during labour, in the cord blood and in the placenta.]** *C.R. Soc. Biol.*, 1955, **149**, 1986–1988. [Inst. Pasteur.]

In 30 women delivered at term and 9 delivered after between 6 and 8 months' gestation, the vitamin B_{12} content of the serum was estimated during labour. The vitamin was estimated also in the cord blood at birth and in an aqueous extract of the placenta. The average content of vitamins B_{12} in mμg. per ml. was for maternal blood at term 0·31 with range 0·08 to 0·62 and for the cord blood 0·56 with range 0·26 to 1·55. In only one woman at term was the value for maternal blood higher than for cord blood, 0·31 and 0·28, respectively.

Of the 9 women delivered prematurely, the maternal and cord blood had the same vitamin B_{12} content in 4, and the maternal value was higher in 1; in the remainder the maternal value was lower.

The placenta contained on the average 18·4 mμg. vitamin B_{12} per g. fresh tissue, range 6·3 to 36·3, and is considered to be a poor storage place for the vitamin.—F. E. Hytten.

5039

Chow, B. F., Wood, R., Horonick, A. and Okuda, K. **Agewise variation of vitamin B_{12} serum levels.** *J. Gerontol.*, 1956, **11**, 142–146. [Dept. Biochem., Sch. Hyg., Johns Hopkins Univ., Baltimore, Md.]

Vitamin B_{12} was estimated with *Lactobacillus leichmannii* in blood serum from 65 subjects aged from 19 to 40 and from 145 aged from 58 to 89 in 5 institutions, and from 114 randomly selected subjects aged from 10 to over 70 years. In all

groups there was less vitamin B_{12} in the serum with increasing age. When the values were grouped by decades a statistically significant regression was obtained.

A study of 70 rats on stock diet gave a similar result with steady decrease in vitamin B_{12} content of the blood serum with increase in age from 2 weeks to 36 months.

Differences between successive estimations of vitamin B_{12} in the same samples of blood from some of the human subjects, or in separate samples from the same subject, were investigated and were found to be less than the differences due to age.

A. M. Copping.

ALLEGRA, G. and NIUTTA, R. Ricerche sui bilanci e sulle relazioni di equilibrio di alcune vitamine (riboflavina, acido folico, vitamina B_{12}) in soggetti normali e in pazienti con sindromi intestinali croniche. 2. Il bilancio della vitamina B_{12}. [**Studies of the balance and equilibrium relationships of some vitamins (riboflavin, folic acid, vitamin B_{12}) in normal subjects and patients with chronic intestinal disturbances. 2. Vitamin B_{12} balance.**] *Acta vitaminol.*, 1956, **10**, 71–77. [Clin. Malatt. Infett., Univ. Messina.] French, English, German and Spanish summaries.

For part 1 see Abst. 3638, Vol. 24.

Vitamin B_{12} was estimated with *Lactobacillus leichmannii* 7830 ATCC in the blood serum before and 1, 2, 4 and 7 hr. after, and in the urine also 24 hr. after, intramuscular injection of 100 μg. vitamin B_{12} in 3 normal subjects, 5 with chronic diarrhoea and 4 with acute diarrhoea.

In the blood serum, the mean value before injection was highest in the normal subjects and lowest in those with acute diarrhoea. After injection of vitamin B_{12} the mean value rose at once, and began to fall again after the first hour except in those with acute diarrhoea, where it was higher in the fourth than in the first hour; after 7 hr., in all 3 groups the mean value was near that before injection.

In the urine, less of the whole dose of vitamin B_{12} was excreted in 24 hr. by those with chronic diarrhoea than by the normal subjects, and still less by those with acute diarrhoea. In those with diarrhoea, urinary excretion was greatest in the first hour but in the normal subjects it was highest in the third and fourth hour. In all groups there was a temporary drop in the second hour. Between the seventh and twenty-fourth hours there was little change in the rate of excretion.

THOMAS, J. W. and ANDERSON, B. B. **Vitamin B_{12} content of normal and leukaemic leucocytes.** *Brit. J. Haematol.*, 1956, **2**, 41–43. [Dept. Pathol., Postgrad. Med. Sch., Ducane Rd., London, W.12.]

There was no significant difference in the concentration of vitamin B_{12}, as estimated with *Euglena gracilis*, between leucocytes from the blood of normal subjects and those of 8 patients with different types of leucaemia, whether the plasma vitamin B_{12} value was within normal limits or raised as it was in those with myeloid leucaemia. With the exception of one of the 4 patients with myeloid leucaemia, in whom a high value was found, there was no significant difference in vitamin-B_{12}-binding power of the homogenised leucocytes from the different subjects.—L. Wills.

5042

MOLLIN, D. L. and ROSS, G. I. M. **Serum vitamin B_{12} concentrations in leukaemia and in some other haematological conditions.** *Brit. J. Haematol.*, 1955, **1**, 155–172. [Dept. Pathol. Haematol., Postgrad. Med. Sch., Ducane Rd., London, W.12.]

The concentration of vitamin B_{12} was considerably higher than normal in the serum of patients with untreated, chronic, myeloid leukaemia; there was no correlation between the leucocyte count or proportion of mature and immature cells in the blood or bone marrow and the concentration of vitamin B_{12} in the serum, but in patients who responded well to treatment there was a fall in the vitamin B_{12} concentration approximately parallel to the fall in the leucocyte count, though the initial fall in the vitamin concentration was often delayed; the vitamin value fell to within the normal limits in a few patients only.

In patients with subacute myeloid leukaemia, polycythaemia rubra vera, myelosclerosis and chronic non-leukaemic leucocytosis, all conditions with increased granulocyte counts, the mean serum vitamin B_{12} concentration was raised, though many values fell within the normal range. In patients with undifferentiated leukaemia, acute or chronic lymphatic leukaemia, " acute stem-cell " leukaemia, myelomatosis, agranulocytosis or aplastic anaemia, the serum vitamin B_{12} concentration was normal. There was no increase in the concentration in the tissues of a patient with a high serum concentration and the concentration in leucocytes was low compared with that in other tissues. The vitamin B_{12} binding capacity of the serum of patients with chronic myeloid leukaemia was very high and was not saturated; the increase was always associated with increased granulocyte proliferation, and it is suggested that the binding material is liberated by the breakdown of granulocytes and that once released it remains for some considerable time in the serum.—L. Wills.

TRUSCOTT, B. and HOOGLAND, P. L. **The constituents of cod liver with vitamin B_{12} activity for *Lactobacillus leichmannii*.** *Canad. J. Biochem. Physiol.*, 1956, **34**, 191–196. [Fish. Res. Board Canada, Halifax, N.S.]

A cod liver residue almost free from oil was found to be a rich source of vitamins of the B complex and of protein. Its total vitamin B_{12} activity was estimated microbiologically with *Lactobacillus leichmannii*. Vitamin B_{12} components were identified by physico-chemical fractionation, and the presence of cyanocobalamin, hydroxocobalamin and deoxyribosides of several purine and pyrimidine derivatives was demonstrated. In total activity and distribution of vitamin B_{12} components the residue resembled beef liver. The use of cod liver residues in pharmaceutical and stock feeding preparations is considered.—A. M. Copping.

WOODRUFF, C. **Infantile scurvy: the increasing incidence of scurvy in the Nashville area.** *J. Amer. Med. Assoc.*, 1956, **161**, 448–456. [Dept. Paediat., Sch. Med., Vanderbilt Univ., Nashville, Tenn.]

According to records made at Vanderbilt University Hospital between 1926 and 1954 scurvy was diagnosed in 103 infants of whom 70 were aged from 7 to 11 months. The incidence per 1000 visits to the outpatients' department was found to have increased during the period from 0·10 to 0·94. There was no evidence that the incidence was seasonal. The commonest physical finding was costochondral beading, seen in 80 patients. X-ray examinations of the long bones showed, in 88 patients, changes at the junction of the cartilage and shaft, where cortical atrophy, atrophy of the trabecular structure or thickening of the zones of provisional calcification were common. Ninety-eight infants had been artificially fed and 5 had been fed on a proprietary mixture.

Diet histories suggested lack of ascorbic acid in 92 ; there were doubts about the truth of statements that the remaining 11 had been having adequate amounts of ascorbic acid. Possible causes for the increase in incidence of scurvy are considered.—D. Harvey.

5047

ANDERSSON, M., WALKER, A. R. P. and FALCKE, H. C. **An investigation of the rarity of infantile scurvy among the South African Bantu.** *Brit. J. Nutrition*, 1956, **10**, 101–105. [Human Biochem. Res. Unit, S. African Inst. Med. Res., Johannesburg.]

Records of admissions to 2 hospitals in Johannesburg disclosed among 9000 Bantu children under 2 years of age only 4 with infantile scurvy. Thirty-three admitted for malnutrition and 29 with only minor complaints selected as controls were chosen for study. Of the first group, none was breast fed and almost all were having cereal mixtures usually prepared with water. Of the second group 16 were breast fed and 13 got little or no breast milk. Vitamin C was estimated in the blood plasma and in some samples of the food prepared by the mothers.

No evidence of scurvy was found by X-ray examination. Mean values for vitamin C were $0{\cdot}36 \pm 0{\cdot}18$ and $0{\cdot}63 \pm 0{\cdot}33$ mg. per 100 ml. plasma in the malnourished and control groups, respectively. For 16 severely malnourished infants the mean was 0·26, and for 13 in the control group, who were artificially fed, it was 0·42 mg. The vitamin content of the food mixtures ranged from 0 to 0·93 mg. per 100 ml.

It is suggested that the endogenous production of vitamin C cannot be excluded.—D. Harvey.

5048

BROWN, A. **Megaloblastic anaemia associated with adult scurvy : report of a case which responded to synthetic ascorbic acid alone.** *Brit. J. Haematol.*, 1955, **1**, 345–351. [Univ. Dept. Med., Royal Infirmary, Glasgow.]

Severe clinical scurvy and a high degree of megaloblastic anaemia were found in a man known to be suffering from cirrhosis of the liver. Histamine-resistant achlorhydria was present. The megaloblastic anaemia responded completely to treatment with synthetic ascorbic acid while the patient was still having a low-protein, scorbutogenic diet. It is suggested that the anaemia was

due partly to lack of vitamin C and partly to faulty folic acid metabolism resulting from a defect in liver function caused by the cirrhosis.

MORSE, E. H., POTGIETER, M. and WALKER, G. R. **Ascorbic acid utilization by women. Response of blood serum and white blood cells to increasing levels of intake.** *J. Nutrition*, 1956, **58,** 291–298. [Sch. Home Econ., Univ. Connecticut, Storrs.]

Nineteen mentally retarded women aged from 27 to 64 years were given a diet restricted in ascorbic acid (see earlier work, Abst. 4163, Vol. 25) for 6 weeks and then received daily supplements of 25, 50 and 100 mg. ascorbic acid for successive periods of 5 weeks. The average daily intake of ascorbic acid from the diet, estimated from 32 random samples taken near the beginning and end of the experiment, was 33 mg. with a range from 24 to 44 mg. The average value for ascorbic acid in the serum on the unsupplemented diet fell from 0·97 to 0·47 mg. per 100 ml., then rose to 0·74, 1·47 and 1·69 at the ends of the successive periods with supplements. Corresponding values for the white blood cells were from 29·94 to 19·55, 26·67, 34·55 and no further increase with the highest supplement. The fluctuations in the white blood cell values reflected those in the serum but were less wide and, with a daily intake of between 33 and 83 mg. ascorbic acid, the average serum value was a good indicator of the concentration in the white cells.—A. Hepburn.

NAMYSŁOWSKI, L. Spostrzeżenia nad zapotrzebowaniem na witaminę C u sportowców w zależności od wysiłku fizycznego. [**Investigations of the vitamin C requirement of athletes during physical exertion.**] *Rocz. Państwowego Zakł. Hig.*, 1956, **7,** 97–122. Russian and English summaries.

The influence of physical exertion on the values for ascorbic acid in the urine and blood serum of athletes, varying from 4 to 13 in number at different stages of the investigation, and on the results of saturation tests was studied while the men were maintained on a constant diet. In most of them there was a periodic deficiency of ascorbic acid, and the loss in the urine and the concentration in the blood serum tended to decrease with a daily dose of 100 mg. during skiing exercise and during normal activities at a physical culture academy. With an intake of 300 mg. the ascorbic acid concentrations tended to increase. One skier supplied with adequate ascorbic acid showed a sharp decrease in ascorbic acid excretion. The daily amount of ascorbic acid recommended at skiing camps was from 200 to 250 mg. and during normal activities at a physical culture academy from 100 to 150 mg. (From English summary.)—A. Hepburn.

SCAGLIONE, G. and COCCIANTE, G. Osservazioni sull'azione di alcuni fattori di accresimento (vitamin T Goetsch, vitamina B_{12}, metilandrostendiolo) negli immaturi. [**Effect of certain growth factors, vitamin T Goetsch, vitamin B_{12} and methylandrostenediol, on premature infants.**] *Pediatria*, 1955, **63**, 1038–1054. [Ist. 1. Clin. Pediat., Univ. Rome.] English, French, Spanish and German summaries.

Of 70 premature infants weighing from 1570 to 2450 g. at birth, 3 groups of 20 were given daily, for 28 days from the second day of life, vitamin T Goetsch or vitamin B_{12} or methylandrostenediol, and the remaining 10 were left untreated. None of the supplements caused disturbance. The infants were fed on human milk, most of them being breast fed. The range of the mean daily weight increase in g. was for those given vitamin T Goetsch from 17·85 to 41·72, for those given vitamin B_{12} from 10·00 to 30·71, for those given methylandrostenediol from 10·00 to 39·28, and for those given no supplement from 6·00 to 18·90. All the infants lost weight for the first 2 days; the average number of days in which the birth-weight was regained was, in the same order, 9, 13, 15 and 19.—E. M. Hume.

PETUELY, F. Über das Bifidus-Problem. [**The bifidus problem.**] *Münch. med. Wochenschr.*, 1956, **98**, 263–266; 304–307. [Biochem. Lab., Zool. Inst., Univ. Graz.] English and French summaries.

The present knowledge of the bifidus problem is reviewed in a lecture. The stools of a breast-fed infant yield an almost pure culture of an organism called *Lactobacillus bifidus*, but the stools of an artificially fed infant yield a mixed culture. A gut flora is not accepted as being a bifidus flora unless from 60 to 70 per cent. of the organisms can be Gram-stained. If a breast-fed infant develops a local infection, perhaps in the middle ear, the bifidus flora is replaced by a mixed flora like that in the artificially fed infant. When the infection is past the bifidus flora is restored. It is concluded that it must be some change in the host that brings about the change, and the state of the bifidus flora in the gut of a breast-fed child is regarded as diagnostic of that child's condition in relation to infection.

Imitation human milk has not been found successful in maintaining a bifidus flora. If about half the breast milk is replaced by milk with semolina or maize starch, the bifidus flora disappears, but if the supplementary feed contains 7 per cent. lactose, and if as little as from one-fifth to one-sixth of the food is human milk, the bifidus flora can be maintained. If, however, there is no human milk, the presence of lactose does not suffice. It is, therefore, argued that human milk must contain an unknown factor which is present in an amount about five times the minimum requirement. Human milk from which protein, fat and carbohydrate have been removed is still able to initiate a bifidus flora in artificially fed babies, but the lactose content must be at least from 2·6 to 3 times greater than the protein content, which may be very low indeed; the lactose content can then be very low also.

The factor in human milk that promotes the bifidus flora is regarded as a means of protecting the infant against intestinal infections until it has developed a natural resistance to them.

A distinction is made between the true bifidus factor and a Penn factor which promotes the growth of a variant of *L. bifidus*, called *L. bifidus* var. Pennsylvania. It was isolated in the U.S. but is not the essential organism of the bifidus flora in the breast-fed infant.

The lecturer describes his own attempts to ascertain the nature of the bifidus factor and to find other sources for it. Materials were tested for their activity on artificially fed babies. A test should include 5 infants and last for 5 or 6 days. From such tests it was concluded that the bifidus factor contains no nitrogen and is of the nature of a carbohydrate. Concentrates of bifidus factor could change the gut flora in as little as 8 hr., but usually from 24 to 96 hr. were required. Children

up to 1½ years could respond, and some change was brought about even in adults.

L. bifidus could grow in a simple synthetic medium without bifidus factor. No evidence was obtained that *L. bifidus* maintains the purity of its cultures by excreting some bacteriostatic substance, or by producing an acid medium, for the medium is often alkaline.

Sudden changes in the weather and mild respiratory infections caused spontaneous fluctuations in the purity of the bifidus flora.—E. M. Hume.

GOOSE, D. H. and JONES, H. P. A. **An introductory study of the self-cleansing action of the mouth.** *Brit. Dent. J.*, 1956, **100,** 272–275.

Children between 8 and 9 years of age and 36 in number were given 10 g. white or brown bread to eat and were asked to say when it had gone from their teeth. Their mouths were then examined for food particles. They could be arranged in 2 groups, one described as aware, whose average time was 5·26 min. and who were correct in their statement, the other described as unaware, whose average time was 10·08 min. and who still had debris clinging to their teeth. Muscle action was recorded, by palpation, as good, fair or poor in 22, 12 and 2 subjects, respectively, for whom mean cleansing times were 5·4, 7·3 and 11·5 min. There was no relation between cleansing time and DMF rate.

Instruction may be necessary in this self-cleansing of the mouth as well as in brushing the teeth.—D. Harvey.

FORREST, J. R. **Caries incidence and enamel defects in areas with different levels of fluoride in the drinking water.** *Brit. Dent. J.*, 1956, **100,** 195–200. [Minist. Health.]

Complete dental examinations were made of schoolchildren aged 12 to 14 years who had spent all their lives in areas where water supplies had different F contents. The fluoride areas were West Mersea, Burnham-on-Crouch and Harwich, all in Essex, with 5·8, 3·5 and 2·0 p.p.m. in their water supplies and Slough, in Buckinghamshire, with 0·9 p.p.m.; non-fluoride areas were Saffron Walden in Essex and Stoneleigh in Surrey with from 0·1 to 0·2 p.p.m. The numbers of children were 324 in fluoride and 259 in non-fluoride areas.

Average numbers of decayed, missing and filled teeth were 2·8, 1·4, 1·5, and 2·6 in the fluoride and 6·6 and 6·1 in the non-fluoride areas, respectively. In the same order of groups the percentages of children free from caries were 24, 50, 35, 30, 4 and 8 and the percentages of first permanent molars which were sound 61, 76, 68, 59, 22 and 22. In the fluoride areas the indices of mottling of enamel, excluding idiopathic spots, were 2·5, 1·9, 0·7 and 0·2; in the non-fluoride areas there were defects resembling fluoride mottling but, to a dentist, distinguishable from it.

The conclusion is that 1 p.p.m. F in a water supply is the optimum amount for prevention of caries and formation of good teeth. The relation of mottling of teeth to the nutritional state of the child will be the subject of a later report.

D. Harvey.

FINN, S. B. and DEMARCO, C. **The effect of artificial water fluoridation on the solubility of tooth enamel.** *J. Dent. Res.*, 1956, **35,** 185–188. [Bur. Dent. Health, New York State Dept. Health, Rochester.]

Deciduous teeth, free from caries and lost naturally, were examined from 3 groups of children. Two groups were in Newburgh, N.Y., one of children whose teeth had erupted before fluoridation of water began but who had had treated water for 5 years, the other of children who had been born since fluoridation began. The amount of F was from 1 to 1·2 p.p.m. The third group, in Rochester, N.Y., drank water relatively free from F. Solubility of the powdered enamel in acetic acid : sodium acetate buffer solution, *p*H 4, was measured by a modification, which is described, of the method of Volker (*Thesis, Univ. Rochester*, 1939 : see also Abst. 927, Vol. 10). From 50-mg. samples numbering 10, 5 and 15 in the above order the average amounts undissolved were 36·65, 38·60 and 36·12 mg., respectively.

The difference between the second and each of the other means was significant ; that between the first and third was not so. In a brief discussion it is suggested that the effect of F is topical and that water treatment is the best means of providing F.—D. Harvey.

BLACKWELL, R. Q. and FOSDICK, L. S. **Studies on the physicochemical phenomena related to dental caries. 3. The effect of sucrose upon the solubility of human dental enamel.** *J. Dent. Res.*, 1956, **35,** 210–219. [Dept. Chem., Northwestern Univ. Dent. Sch., Chicago, Ill.]

3. For parts 1 and 2, physico-chemical studies of effects of sucrose on ion diffusion through semi-permeable membranes, see Forscher and Fosdick, *J. Dent. Res.* 1954, **33,** 206 ; 212.

Dental enamel pooled from non-carious adult molars and in amounts of 50 mg. was shaken at 37° C. with 20 ml. buffered lactate solution alone or with 0·5 or 1·0 *M* sucrose ; amounts were measured of Ca going into solution during 7 periods of time from 5 to 240 min. and 5 *p*H values from 4·0 to 6·0 at 0·5 unit intervals and of P with the same solutions at *p*H 5·0, 5·5 and 6·0. Data for these are tabulated with the values for Ca : P ratio.

The effect of sucrose was to reduce the amounts of both Ca and P which went into solution ; that effect was least at *p*H 4·0 and 6·0. The Ca : P ratio ranged from 2·0 to 4·1, mean 2·7, but the findings followed no pattern in relation to time, *p*H or concentration of sucrose.

Possible mechanical or physical roles of sucrose are discussed in terms of viscosity of the solution, a coating effect of the sugar molecules, formation of Ca-sugar complexes and a reduction *in vivo* of free water molecules with consequent increase of H ions.—D. Harvey.

5068

KRIDAKARA, O., BOOZAYAANGOOL, R., YUKTANANDA, I. and VOLKER, J. F. **Dental survey of selected Thai children : nutritional observations.** *Amer. J. Clin. Nutrition*, 1956, **4,** 280–284. [Dent. Sch., Univ. Med. Sci., Bangkok.]

See Title 2287, Vol. 23.

The dental health of children between 4 and 18 years of age attending different types of school in Bangkok was studied ; 552 were in Thai, 239 in Chinese and 225 in Islamic schools. There was some evidence that Chinese schools had fewest children free from caries ; for numbers of decayed and filled teeth and for state of health of gums and of occlusion of teeth differences between groups were small.

The Thai children in Bangkok were compared with 2 other groups of Thai children, 673 Chiengmai and 652 Lampang, living up-country under conditions with less contact with western civilisation. The percentages of children free from caries were, respectively, 8, 55 and 38 ; the difference between the 2 up-country groups was accounted for largely by the data for a single mission school in Lampang. In all 3 groups condition of gums was comparable, the percentage recorded as normal never exceeding 50. Occlusion was best at Chiengmai where 60 per cent. of the children were normal ; records of poor occlusion were commonest in Bangkok, where only 24 per cent. of the children were normal.

The high rate of incidence of caries in Bangkok may be the result of the great increase in use of sugar and imported wheat. Official estimates of these for 1945 and 1949 are sugar 7270 and 28,424 and flour 100 and 10,210 metric tons. Most was used in the Bangkok area.—D. Harvey.

5069

KNIZHNIKOV, V. A. O vzaimosvyazi mezhdu soderzhaniem ftora v vode, flyuorozom i kariesom. [**The interconnection between the fluorine content of water and fluorosis and caries.**] *Gigiena Sanit.*, 1955, No. 10, 13–17. [Kazakh. Inst. Epidemiol., Mikrobiol. Gigien.]

In a study in Central Kazakhstan of dental fluorosis in 2202 persons, mainly schoolchildren, 4 degrees were recorded. Estimations were made also of F, I and Ca in drinking water, which was from lakes and wells. In general severity of fluorosis was associated positively with the F content of the water, but in some areas there was inconsistency. In 2 districts each with 4 mg. F per litre the incidence of Type 1 fluorosis, slight spots or stripes distributed symmetrically, was 1½ times greater in one than in the other ; of 2 others,

one with 2·2 mg. and the second with 6 mg. F per litre, Type 1 fluorosis was commoner in the first.

Among children the relations of incidence of caries to F content of drinking water was not consistent. When, for districts with different amounts of F, subjects were arranged according to severity of fluorosis, the incidence of caries was greater among those with severe fluorosis, Type 3, showing multiple erosion and yellow-brown staining, and among those without fluorosis than in those with mild, Type 1 fluorosis. Within each fluorosis group caries increased with rise in F content of water; for the group with Type 1 the increase was small.

Among persons who migrated to a district where drinking water contained 4 mg. F per litre, the younger the age at entry the greater the incidence and severity of fluorosis; if the age had been from 8 to 12 years, fluorosis was absent and the incidence of caries low.—F. Billewicz.

5070

SHAW, J. H., GUPTA, O. P. and MEYER, M. E. **High fluoride content of teeth from communities with low fluoride water supplies.** *Amer. J. Clin. Nutrition*, 1956, **4,** 246–253. [Harvard Sch. Dent. Med., Boston, Mass.]

The findings in a number of surveys in India and the United States are summarised to show that the proportion of children free from caries is much higher in India.

Analytical data are presented for 161 teeth from 52 persons in Delhi, for 75 teeth from 36 in Bombay and for 58 teeth from 35 in Boston. The Delhi population could be subdivided into 2 groups, one of 28 permanently resident there and drinking water with 0·25 p.p.m. F, the other of 24 who came from other parts and who in their earlier life had had water of unknown composition. For these 2 groups, respectively, the average amounts of F were in enamel 299, 305 and in dentine 710, 706 p.p.m. For the Bombay population with 0·04 p.p.m. F in its drinking water the averages were 184 p.p.m. for enamel and 456 p.p.m. for dentine. For the Boston population investigations were in two stages with a considerable interval, but at each stage the F content of the water was 0·12 p.p.m. The averages in the first stage for 30 teeth from 17 persons were enamel 40 and dentine 85 p.p.m., and in the second, for 28 teeth from 18 residents, enamel 58 and dentine 109 p.p.m. F. Also the Indian teeth were less carious, had higher gloss and translucency and had roots more resistant to cutting.

The differences in favour of the Indian teeth could not be explained from what is known about amounts of water drunk by Indians (*cf.* Pandit *et al.*, Abst. 3695, Vol. 10) or from the use of sea salt. There is, it is suggested, need for more analyses of local foods and further study of absorption and utilisation of F by Indians.—D. Harvey.

Molina Nuñez, J. El factor psíquico en la nutrición. [**Psychic influences on nutrition.**] *Medicamenta*, 1956, **25,** 253–254. [Hosp. Psiquiát., Guadalajara.]

Nutrition cannot be considered in isolation, but the general bodily and mental condition of the subject must be taken into account. Vomiting in pregnancy, obesity and other disturbances should be dealt with in this way, but a plea is made that the separate classification of "psychosomatic" disorders should be abandoned.—D. Duncan.

DIABETES

5078

Read, C. H. and Baer, P. E. **Diabetes in children.** *Pediatrics*, 1956, **17,** 605–611. [Dept. Paediat., Coll. Med., State Univ. Iowa.]

5079

Larsson, Y. and Ström, L. **Treatment of juvenile diabetes, with particular reference to diet.** *Ann. paediat.*, 1956, **186,** 270–281. [Paediat. Clin., Crown Princess Lovisa's Hosp., Stockholm.] German and French summaries.

In the paediatric clinics in Stockholm clinical rather than chemical or symptomatic control of diabetes is advocated. The necessity for careful medical treatment with adequate insulin is stressed, a normal diet being allowed. Glycosuria to the extent of from 20 to 40 g. per 24 hr. and post-alimentary blood sugar up to 300 mg. per 100 ml. are permitted.

Arguments for and against different methods of treatment are discussed critically.—F. C. Aitken.

Wolf, H. J. and Priess, H. Erfahrungen mit fettfreier Kost beim Diabetes mellitus. [**Trials with fat-free diet in diabetes mellitus.**] *Deutsch. med. Wochenschr.*, 1956, **81,** 514–515. [Städt. Krankenhaus, Bielefeld.]

Diabetics who had for 8 to 10 days been having a diet with 140 to 225 g. carbohydrate, some with insulin, were given for 18 days an almost fat-free diet of potatoes, rice and fruit; towards the end gelatine and white of egg were added, and subsequently, for 8 to 10 days, protein foods low in fat, *e.g.*, haddock, cod, lean veal, and 30 to 50 g. fat in the form of vegetable oil and butter. In evaluating the results, patients who improved so much on the fat-free diet that their insulin had to be cut down were excluded; this left 60, of whom 33 had insulin. The results are shown graphically.

Mean blood sugar fell from 218 mg. per cent. to 163 on the fat-free diet and rose to 181 on the fat-restricted diet; urinary sugar from 37·1 g. in 24 hr. to 4·1, rising to 9·1. The effects were irrespective of sex, duration of diabetes, or use of insulin or not, but the effect on blood sugar was less in those over 60. In 10 patients tested with both 30 and 50 g. fat, the rises were almost proportional to the amounts of fat. Ten of the 60 had acetonuria, which speedily vanished, and 8 had gangrene of the feet, which improved. At first the fat-restricted diet was unpopular, but the immediate benefits changed the patients' attitudes.

The amount of fat allowed is about the average consumption found by Voit in Munich at the turn of the century and used by him as a standard for mass feeding.—W. M. Deans.

5082

Joelson, R. H. **The effect of oral dextran on blood glucose.** *Amer. J. Clin. Nutrition*, 1956, **4,** 279. [Diabetes Clin., Mount Sinai Hosp., New York.]

Four subjects with mild diabetes and 1 subject with hyperinsulinism were given 400 ml. of 5 per cent. unhydrolysed dextran. No significant increase in blood sugar occurred in any patient.

F. C. Aitken.

5083

Ridolfo, A. S. and Kirtley, W. R. **Clinical experiences with carbutamide, an orally given hypoglycemic agent. Preliminary report.** *J. Amer. Med. Assoc.*, 1956, **160,** 1285–1288. [Lilly Lab. Clin. Res., Gen. Hosp., Indianapolis, Ind.]

Carbutamide or BZ 55 (1-butyl-3-sulphanilylurea) lowered the blood sugar of 9 of 11 diabetics treated in hospital and of 7 treated as outpatients, their diets remaining unaltered; the amounts given were generally 2·5, 1·5 and 1 g. on successive days, with 1 g. daily for maintenance. Six case histories are given. Only 1 of 31 patients had undesirable side effects. Favourable indications

were maturity, obesity and relatively mild diabetes of short duration ; the drug was useless for patients with diabetic acidosis or young people with unstable diabetes.—W. M. Deans.

5084

BOULIN, R. Essais de traitement du diabète sucré par le BZ 55. [**Treatment of diabetes mellitus with BZ 55.**] *Presse méd.*, 1956, **64,** 643–645. [Paris.]

The hypoglycaemia-inducing sulphonamide BZ 55 was used in the treatment of 15 diabetic patients aged between 37 and 80 years. Treatment, as judged by effect on blood sugar and glycosuria, was successful in 13 cases.—F. C. Aitken.

5085

RAVINA, A. Étude d'un nouveau sulfamide antidiabétique : indications cliniques et posologie. [**A new antidiabetic sulphonamide : clinical indications and dosage.**] *Presse méd.*, 1956, **64,** 646–649. [Paris.]

N_1-sulphanilyl-N_2-*n*-butylcarbamide (BZ 55) reduced glycosuria and levels of blood sugar in 9 elderly diabetic patients.—F. C. Aitken.

5086

BLANCO-SOLER, C. La nueva terapéutica peroral de la diabetes. (Nota clínica previa.) [**The new peroral treatment of diabetes. Preliminary clinical note.**] *Medicamenta*, 1956, **25,** 247–252. [Serv. Med. Nutrición, Hosp. Central Cruz Roja.]

There were 5 control subjects, healthy or with disorders other than diabetes, and 10 adults with compensated diabetes, never very severe. Blood sugar was estimated before and after treatment and sugar in urine during treatment for 6 days with BZ 55 (see Abst. 2402, Vol. 26).

The treatment had no significant effect on the 5 non-diabetic subjects. In 8 diabetic subjects treatment with BZ 55 produced a slow but considerable fall in sugar in blood and urine, beginning about 48 hr. after the first dose. One subject with disturbed carbohydrate metabolism, but not diabetes, had after treatment symptoms of hypoglycaemia. In one normal and one diabetic subject treatment did not affect the response to a double blood sugar tolerance test. No subject showed any significant change in blood cholesterol or urea, plasma proteins, pulse, temperature or arterial pressure. Subjectively they were well, except that 1 patient had gastric pain which responded to alkali. The dose of BZ 55 must be decided by the reactions of the patient. Protocols are reproduced for each subject.

Treatment with BZ 55 seems to offer promise, at least in adult subjects not severely affected.

D. Duncan.

5087

BÄNDER, A. *et al.* Über die orale Behandlung des Diabetes mellitus mit N-[4-Methyl-benzolsulfonyl]-N′-butyl-harnstoff (D 860). Klinische und experimentelle Untersuchungen. [**Treatment by mouth of diabetes mellitus with N-[4-methylbenzenesulphonyl] - N′ - butylurea (D 860). Clinical and experimental studies.**] *Deutsch. med. Wochenschr.*, 1956, **81,** 823–846 ; 887–906. English and Spanish summaries.

D 860 (N-[4-methylbenzenesulphonyl]-N′-butylurea, Rastinon (Hoechst A.G., Frankfurt), Artosin (C. F. Boehringer und Söhne G.m.b.H., Mannheim)) has the same chemical structure as BZ 55 except that a methyl group replaces the amino group attached to the benzene ring. Results are reported of very extensive co-operative clinical, chemical and experimental studies (animal studies pp. 889–904) of the effects of D 860 given by mouth, made in medical clinics of the universities of Frankfurt, Freiburg and Munich and of the municipal hospitals of Augsburg and in diabetes institutes at Garz (Rügen) and Karlsberg, as well as in the pharmaceutical laboratories of Hoechst A.G. In all, 751 diabetic patients have been treated since August 1955.

In brief, D 860 does not cure diabetes, but in doses of 3 g., falling generally to 0·5 g. daily, can partly or wholly replace insulin for certain patients, especially the middle-aged and elderly, the obese, those with diabetes of short duration and those requiring only small amounts of insulin (or none). Diet remains important, though some were allowed 240 or 264 g. carbohydrate daily. Post-mortem examination of the pancreas of 6 diabetic patients dead from other causes, who had had D 860, showed no sign of damage to the alpha cells, and 4 in whom the diabetes had responded to D 860 had numerous beta cells, though there was no clear evidence that D 860 stimulated the activity of these. A decrease in lactic acid in the blood of patients successfully treated with D 860, and an increase in liver glycogen in animals, suggested that D 860 may act by affecting liver enzymes.

W. M. Deans.

5088

POCHE, R. and SCHUMACHER, K. T. Über Zusammenhänge zwischen Diabetes mellitus und Leberzirrhose. [**Association between diabetes mellitus and cirrhosis of the liver.**] *Deutsch. Ztschr. Verdauungs- u. Stoffwechselkr.*, 1956, **16,** 68–78. [Pathol. Inst., Med. Akad., Düsseldorf.]

Analysis of 5079 records of post-mortem examinations of subjects over 20 years of age at death gave 217 with diabetes. Cirrhosis, all types, was found in 47 of these, cirrhosis with small nodules of unknown etiology in 26. On either basis,

incidence was roughly three times expectation and diabetes is therefore thought to predispose to cirrhosis of the liver.—I. Leitch.

GASTRO-INTESTINAL CONDITIONS

5089

MARKOVA, G. F. Vliyanie udlinennogo medikamentoznogo sna v sochetanii s lechebnym pitaniem na techenie yazvennoi bolezni. [**Influence of prolonged induced sleep in conjunction with therapeutic diet on the course of ulcers.**] *Vop. Pitan.*, 1956, **15,** No. 3, 12–16. [Inst. Pitan., Akad. Med. Nauk SSSR, Moscow.]

The patients were 45 men and 5 women from 21 to 60 years old, 9 with gastric and 41 with duodenal ulcers. Most of them had been affected for a long time and 28 had had massive haemorrhage, perforations or peritonitis. They were treated with rest in bed and diet and given luminal, sodium amytal or chloral hydrate in doses sufficient to induce sleep for 11 or 12 hr. nightly for 2 or 3 weeks.

The sleep was considered an extremely valuable adjunct to diet and gave good results with most of the patients. They gained in weight up to 6·3 kg., average 1·3 kg.—D. Duncan.

5090

WINKELSTEIN, A. and SCHWEIGER, E. **Complete nutriment for the therapy of peptic ulcer.** *J. Amer. Med. Assoc.*, 1956, **160,** 1111–1113. [Dept. Med., Mount Sinai Hosp., New York.]

The neutralising properties of Sustagen, a proprietary high-calorie powder, given with water, were tested in 30 patients, most of whom had gastric hypersecretion. The excellent results suggested the possible value of the product in the treatment of peptic ulcer by diet.—F. C. Aitken.

5091

SÁNCHEZ AGESTA, A. and ESPINAR LAFUENTE, M. Tetania con hipopotasemia en la estenosis pilórica. [**Tetany with low blood potassium in pyloric stenosis.**] *Rev. clín. española,* 1956, **60,** 296–304. [Clín. Méd., Univ. Granada.] English, German and French summaries.

An elderly man, thought to have pyloric stenosis resulting from an ulcer, entered hospital but refused operation. He was undernourished after liquid diet and continual vomiting and was given a bland diet with atropine, liver extract and vitamin C. In hospital he suddenly developed severe tetany, which lasted for 3 days and was followed by paralysis and confusion. Serum Ca was not low, but calcium gluconate was given from the second day of tetany, and also isotonic saline. Serum P was low initially, but rose with treatment; serum K, which was about 4·5 m. equiv. per litre, fell below 4 as the tetany subsided, and reached 4·5 again only when the paralysis ended 16 days after the onset of tetany. Changes in the electrocardiogram are discussed. Depletion of K, probably aggravated by administration of Na, was an important if not the only cause of the tetany.

THYROID DISEASE

5093

HETTCHE, H. O. Epidemiologie und Ätiologie der Struma in 100 Jahren Forschung. [**Epidemiology and etiology of goitre in one hundred years of research.**] *Arch. Hyg., Berlin,* 1956, **140,** 79–105. [Intersuchungsanst. Städtehyg., Hyg. Inst., Hamburg.] French and English summaries.

In a review of endemic goitre the aspects considered include geography, topography, local hygiene, hygiene of water, bacteriology and epidemiology. The author concludes that endemic goitre is caused by an injurious substance which occurs in contaminated water supplies. The toxic substance belongs to the urochrome group, it binds copper in the serum and, in animal experiments, it produces goitre which can be prevented by simultaneous administration of iodine.

E. M. Hume.

5094

HUBBLE, D. **Thyroid disorders in childhood.** *Brit. Med. J.*, 1956, i, 875–879. [Derbyshire Hosp. Sick. Child.]

The relations of thyroxine, triiodothyronine and thyroid-stimulating hormone (TSH) to growth and function of the thyroid are discussed. Cretinism is often of genetic origin and inborn errors of metabolism probably account for a high proportion of disorders in children.

The enlargement of the gland at puberty is possibly caused or aggravated by insufficient supply of iodine. Although ample iodine may prevent endemic goitre, its cure requires both iodine, to augment the supply, and thyroxine, to depress TSH activity. Causes of sporadic goitre may be administration of Co for anaemia, or *p*-aminosalicylic acid. Antithyroid drugs and radioactive iodine should be used sparingly for children and pregnant women.—I. Leitch.

5095

RODRÍGUEZ MORENO, F., IBÁÑEZ GONZÁLEZ, R. and ORTIZ DE LANDÁZURI, E. El tiroides de los escolares como control de la endemia bociosa y de la profilaxis. [**The thyroids of schoolchildren as an index of endemic goitre and its control.**] *Rev. clín. española*, 1956, **60**, 154–160. [Dept. Profilaxis Bocio, Clin. Méd., Univ. Granada.] English, German and French summaries.

A study was made in 3 places in Granada; Castaras on the south of Sierra Nevada, Güejar Sierra on the north, where iodised salt had been supplied since 1953, and Granada, the capital. Schoolchildren aged from 5 to 13 years were classified by size of thyroid and the incidence was compared with that in the whole population of the district.

In Castaras 518 of the 840 inhabitants were examined; 54·7 per cent. had frank goitre, 11·7 were borderline. Of 111 schoolchildren 54 had frank goitre and 14 were borderline, *i.e.*, 48 and 12 per cent., about the same as for the general population.

In Güejar Sierra at the beginning of 1953 (see Abst. 1290, Vol. 25) 53 per cent. of the inhabitants had goitre and 23·1 potential goitre [not defined]; in 209 children under 15 the percentages were 51·6 and 26·9. After 2½ years of treatment with iodised salt the percentages in the schoolchildren were 29 and 27 and the absolute numbers 32 and 30 out of 109, and in 36 children aged 6 to 8 only 3 had goitre and 9 potential goitre.

In Granada 217 schoolchildren were studied, 147 boys and 70 girls. The numbers with goitre and potential goitre were 27 and 25 boys, 9 and 21 girls, or, as percentages of all the children, 16 and 21. In Granada city the drinking water contains 1 μg. I per litre, which is apparently not enough to prevent goitre. The beneficial effect of table salt with 20 mg. KI per kg. is shown by the study in Güejar Sierra.—D. Duncan.

ANAEMIA

5096

BUSH, J. A. **The rôle of trace elements in hemopoiesis and in the therapy of anemia.** *Pediatrics*, 1956, **17**, 586–595. [Dept. Med., Coll. Med., Univ. Utah, Salt Lake City.]

This is a review of the roles of Cu, Co and Mo in blood formation and of the possible occurrence of deficiencies in infants. In those with anaemia diagnosed as due to Fe deficiency, values for Cu in serum and red cells were high, not low as expected. Cu deficiency was not produced in 2 infants after 4 and 5 months on diets which produced deficiency in pigs. Values for Cu in serum were found to be low in newborn infants, but their stores of Cu were not low. It was thought that patients with nephrotic syndrome or sprue might be partly depleted of Cu, but no haematological response to Cu has been demonstrated. Doubt is expressed about the clinical value of treatment of anaemia with Co or Mo, and there is danger with Co.

There are 55 references.—D. Duncan.

BROWN, A. **Iron therapy.** *Practitioner*, 1956, **176**, 434–440. [Muirhead Dept. Med., Royal Infirmary, Glasgow.]

5098

SCHLEISNER, P. **Cobalt in anaemia.** *Acta med. scand.*, 1956, **154**, 177–185. [Med. Dept., Horsens Kommunehosp., Denmark.]

After Fe had been given for some weeks without success, Co at the rate of about 30 mg. daily was given to 16 patients with anaemia resulting from glomerulonephritis, pyelonephritis or diabetic nephropathy. In one patient after only 2 doses treatment had to be stopped because of nausea and in 3 others it was given up for the same reason. Ten patients had no nausea.

In 11 of the 15 patients considered, Hb rose significantly, by from 17 to 68 per cent. of its initial value. Successful treatment lasted from 1 to 40 weeks. The patient treated for 40 weeks, with about 14 g. Co in all, complained finally of sore throat and deafness. As she died soon after treatment stopped, it is not known whether hearing would have returned spontaneously.

It is considered that Co is indicated chiefly in disorders like renal anaemia, where the prognosis is bad and late side-effects are relatively unimportant.—D. Duncan.

STIJNS, J. Le traitement de l'anémie ferriprive chez l'enfant par une préparation de fer injectable par voie intramusculaire. [**Treatment of iron-deficiency anaemia in children by intramuscular injection of an iron preparation.**] *Ann. Soc. belg. Méd. trop.*, 1956, **36**, 165–178. [Service Biol. Clin., Inst. Méd. Trop. "Princesse Astrid", Léopoldville.] Flemish summary.

In African infants aged from 5 months to 4½ years microcytic, hypochromic anaemia, generally associated with hookworm infestation, was successfully treated by intramuscular injection, generally in divided doses, of the calculated requirement of iron as Imferon, a complex of iron and dextran. There were no general and only very trivial local reactions to the injections. Early and adequate

treatment of the hookworm infestation was necessary to maintain a normal blood picture. In a few infants smaller doses than those calculated gave satisfactory results.—L. Wills.

CALVO MELENDRO, J. and CALVO MORALES, J. Anemia por leche de cabra. [**Anaemia from goat's milk.**] *Rev. española Enferm. Apar. digest. Nutrición*, 1956, **15**, 41–47. [Hosp. Provincial, Soria.] English summary.

There is a brief review of the literature. An infant received goat's milk from about 15 days of age. He was seen when 9 months old after having had, for a month, diarrhoea, vomiting and loss of weight. He was pale and cachectic and the spleen was palpable. Red cell count was 1·8 million and Hb 28 per cent. [standard not stated]; the blood showed anisocytosis, poikilocytosis and 10 per cent. of megaloblasts; the bone marrow was megaloblastic. The infant was given cow's milk, fruit juice and cereals with injections of vitamin C, liver extract and folic acid. He recovered in a few weeks.

The mother, who also took about 1 litre of goat's milk daily, was pale and had a red cell count of 3·2 million, but her anaemia was normochromic and microcytic. Another woman was seen with the same signs. Her 2-year-old son, who had received nothing but goat's milk for a year, was pale and undernourished and had diarrhoea and chronic blepharitis. His red cell count was 1·4 million, Hb 32 per cent., and megaloblasts were common in blood and bone marrow. Like the other child he responded to mixed diet, liver extract and folic acid.

It is suggested that the goats' feed may have had some bearing on the anaemia.—D. Duncan.

FOY, H. and KONDI, A. **Nutritional and intestinal factors and iron losses in the genesis of tropical anaemias.** *Lancet*, 1956, **270**, 423–424. [Wellcome Trust Res. Labs.]

Hypochromic microcytic anaemia in tropical areas often occurs where there is plenty of Fe in the diet. Hookworm is not considered to be an important cause; in India there was no significant relation between the incidences of anaemia and of hookworm. It is thought that an unbalanced diet or an unbalanced intestinal flora caused by unsuitable diet may limit absorption of Fe. If loss of Fe in sweat is high, and it is estimated to reach 2·3 mg. daily, more Fe may be lost than is absorbed. A large proportion of patients respond to Fe by mouth, others need protein, folic acid or vitamin B_{12}, and deficiencies of these substances may become apparent only after Fe is given.

BJÖRKMAN, S. E. **Chronic refractory anemia with sideroblastic bone marrow. A study of four cases.** *Blood, J. Hematol.*, 1956, **11**, 250–259. [Dept. Med., Univ. Lund.] Interlingua summary.

5103

KEELEY, K. J. and POLITZER, W. M. **Aminoaciduria in the megaloblastic anaemias.** *J. Clin. Pathol.*, 1956, **9**, 142–143. [Baragwanath Hosp., Johannesburg.]

The subjects with megaloblastic anaemia were Africans, 7 women in the puerperium, 2 older women and 2 infants with malnutrition. All of them had normal amounts of amino acids in the urine. A man with Addisonian anaemia in relapse showed abnormal excretion of tyrosine, taurine, lysine, alanine and glycine, which disappeared after treatment with vitamin B_{12} and intrinsic factor. In consideration of the work of Weaver and Neill (Abst. 1299, Vol. 25), it is suggested that estimation of amino acids in urine could be used for differential diagnosis of megaloblastic anaemias.—D. Duncan.

5104

EDGAR, W. and RICE, H. M. **Administration of iron in antenatal clinics.** *Lancet*, 1956, **270**, 599–602. [Pub. Health Dept., Luton, Beds.]

Pregnant women numbering 179 were in 2 groups, to one of which with 89 subjects tablets of ferrous sulphate were given throughout pregnancy.

In the control group without tablets Hb, red cell count, packed cell volume and M.C.H.C. all fell [the fall in M.C.H.C. was small and seems not to have been tested statistically]; in the group given Fe, indices on the average remained steady although in 20 subjects Hb did fall.

It is suggested that as a routine measure every expectant mother should be given Fe.

5106

MACCAFERRI, A. Le anemie senili e loro comportamento nella terapia epatica e marziale. [**Anaemia in old age and its response to treatment with liver and iron.**] *Acta gerontol.*, 1956, **6**, 20–36. [Osp. "M. Malpighi", Bologna.]

The subjects were 6 men and 8 women from 70 to 86 years old, free from signs of disease, but with hyperchromic or normochromic anaemia ascribed to senescence. They received for 15 days large doses of liver extract by subcutaneous injection and then 2 g. reduced iron daily for another 15 days. Blood samples were taken initially and at the end of each treatment. The response of each subject is described in full.

Treatment with liver caused increases in the red cell count in 12 subjects, but the increase was sometimes very small. Treatment with Fe further increased the count in 10 subjects, and the increase was often larger than with liver. Hb was increased by liver in 5 subjects and fell or was unchanged in 8; it was increased by Fe in 10. White cell counts increased in half the subjects and decreased in half on each treatment.

Possible interpretations of the results are discussed.—D. Duncan.

OTHER CONDITIONS

5107

KLINKE, K. Zur Therapie des rekurrierenden ketonämischen Erbrechens. [**Treatment of recurrent ketonaemic vomiting.**] *Deutsch. med. Wochenschr.*, 1956, **81**, 819–820; 849. [Kinderklin., Med. Akad., Düsseldorf.]

The etiology of recurrent ketonaemic vomiting in children is discussed. Disturbance of the regulation of metabolism by the autonomic nervous system is suggested as the ultimate cause. Treatment is by sedatives, supply of carbohydrate and restoration of water, Cl and K balance. In slight cases teaspoonfuls of ice-cold sweetened fruit juice, with 5 drops HCl per 100 ml., may suffice. If dehydration is marked, a 50 : 50 mixture of Ringer solution and 10 per cent. glucose solution, with 1 g. KCl per litre, may be given by drip; or, if the child is too restless, 40 to 50 ml. of the same mixture, with 50 mg. Berolase (cocarboxylase) but without K, by vein.—W. M. Deans.

5108

HAASE, K. E. and HOSENFELD, H. Zur Fettsucht im Kindesalter. [**Obesity in childhood.**] *Ztschr. Kinderheilk.*, 1956, **78**, 1–27. [Kinderklin., Univ. Frankfurt a.M.]

Much of this paper is polemical. In the authors' opinion, endocrine disorder as a cause of obesity in children is greatly overemphasised.

The number of new cases of obesity seen yearly at the Frankfurt Kinderklinik, after remaining low during the war, began to rise in 1948 and in 1954 was nearly five times that before the war. The effect of more abundant food is seen also from the dates of onset of obesity in 181 children seen since 1948 for whom reliable information was got.

Findings are reported for 335 obese children (158 boys, 177 girls) treated as in- or out-patients between 1936 and 1954. The results are shown graphically.

The obese children tended to be tall for their age, and this was true for younger children as well as for those at or just before puberty. A distinction between types of obesity according to age of onset is considered arbitrary. Doubt is cast on the belief that delayed puberty is associated with obesity in boys, and there was some evidence of early menarche in obese girls. It is considered that obese children represent an extreme form of the modern tendency to acceleration of growth.

No connection could be found between birthweight (mean 3497 g. for 135 boys, 3426 g. for 128 girls) and subsequent degree of obesity. There was no conclusive evidence of a connection with diabetes. There was little difference between obese children whose parents and grandparents were obese and those from families which denied a history of obesity (numbers compared small, about 20 of each) in birthweight, age of onset of obesity, excess height or degree of excess weight, except that obese infants were found only among the former.

A follow-up study of 21 males and 29 females, mostly in their twenties, who had been patients before the war, showed that obesity had generally persisted; some had lost weight for a time after puberty, or by dieting, or during the war, but had reverted when food became plentiful again. In view of the bad effects on health of obesity in adults, it is considered that treatment of obesity in children is essential; and that dieting is the most effective and the only safe method.

W. M. Deans.

5109

JOHNSON, M. L., BURKE, B. S. and MAYER, J. **The prevalence and incidence of obesity in a cross-section of elementary and secondary school children.** *Amer. J. Clin. Nutrition*, 1956, **4**, 231–238. [Dept. Maternal Child Health, Harvard Sch. Pub. Health, Boston, Mass.]

Heights and weights of over six thousand children in the towns of Brookline and Newton were obtained from school health records. Wetzel's grid limit for obesity, channel A_4 or above, was the criterion. The overall prevalence rate for boys was $9{\cdot}0 \pm 2{\cdot}5$ per cent. and for girls $12{\cdot}5 \pm 2{\cdot}5$ per cent.

Records of children classed as obese were traced back through the school grades. This showed that there was a history of persistent obesity in one-third of the overweight girls and in about half of the overweight boys. Late obesity accounted for 12 per cent. of the overweight girls and over a third of overweight boys.—F. C. Aitken.

PHEAR, E. A., RUEBNER, B., SHERLOCK, S. and SUMMERSKILL, W. H. J. **Methionine toxicity in liver disease and its prevention by chlortetracycline.** *Clin. Sci.*, 1956, **15,** 93–117. [Dept. Med., Postgrad. Med. Sch., London.]

Patients with liver disease were given 8 to 20 g. *dl*-methionine by mouth daily for up to 7 days. In a group of 9 patients with portal cirrhosis and chronic portal systemic encephalopathy, of whom 8 had extensive portal systemic collateral circulation, methionine caused neurological deterioration in 7. The changes occurred after total doses of from 11 to 46 g. methionine. Seven patients with portal cirrhosis, 3 with extensive collateral circulation, of whom none had previously shown neurological signs, tolerated 50 to 102 g. methionine without neurological change. Intravenous methionine was without effect in 3 of 4 patients who reacted to methionine by mouth; in the fourth, deterioration occurred 2 hr. after the infusion. Neurological signs after methionine by mouth were not associated with change in blood ammonia, *p*H or serum bilirubin nor related to level of methionine, which rose whether there was neurological deterioration or not. Five patients sensitive to methionine by mouth were given chlortetracycline before and during a second course of methionine; neurological deterioration was prevented or delayed. This suggested that the toxic substance might be derived from methionine by the action of intestinal bacteria susceptible to this antibiotic, and bacteriological investigations were made *in vivo* and *in vitro*. The results, presented in detail and discussed, gave no positive explanation of the mechanism of methionine toxicity.

5123

MÄKELÄ, A. **Studies on the question of bulk in the nutrition of farm animals with special reference to cattle.** *Acta agral. fenn.*, 1956, pp. 139.

With reference to the literature, appetite, hunger and repletion, palatability, the role of bulk in animal feeding, the capacity of the digestive tract and the rate of passage of feed through it, and the relation of plane of nutrition to digestibility of the ration are discussed. Experiments with cattle, horses and pigs are reported.

Palatability trials with cattle showed concentrates, potatoes and sugar beet tops to be equal, followed by swedes and A.I.V. silage, then molasses silage, hay and oat straw.

Slaughter trials were made to investigate the capacity of the digestive tract of cows and young bulls given hay to appetite for 10 days. The bulls had less in the reticulo-rumen than the older animals. Changes in the amount of hay given to cows resulted in comparatively small changes in contents of the reticulo-rumen. Of the total contents of the digestive tract 75 per cent. was in the reticulo-rumen. The capacity of the tract was restricted by the gravid uterus and by accumulation of abdominal fat.

When cows were fed to appetite dry matter was retained in the rumen for 24 hr., but for 2 to 3 days when only one-third full-feeding was allowed. With young bulls given the same quantity of feed per 100 kg. liveweight as the cows, feed was retained in the rumen for somewhat longer. Lignin was retained 1·7 times as long as total dry matter at all levels of feeding.

Digestibility of the dry matter of the ration decreased by about 1·5 per cent. when the intake of dry matter increased by 1 kg. per 100 kg. liveweight. N-free extract was thought to be digested and absorbed mostly in the reticulo-rumen.

Bulk or filling capacity of a feed was found to be more closely related to its dry matter content

than to fibre, ballast, or water content. In concentrates 1 kg. dry matter was equivalent to 0·5 kg. dry matter in hay, in potatoes and swedes to 0·6 kg., in fodder cellulose to 0·7 kg., in beet tops to 0·8 kg., and in sugar beet pulp to 0·9 kg. Grass A.I.V. silage, hay and oat straw were similar in this respect.

Wood wool was given to cows getting concentrates and a decreasing amount of roughage, and the amount eaten was taken to indicate the desire for roughage. The minimum requirement of roughage was 0·5 kg. per 100 kg. liveweight. With swedes or beet pulp instead of concentrates the requirement of roughage was considerably less.

Working horses ate from 12 to 14 kg. hay in addition to 3 kg. concentrates. On the first day of rest after working an extra kg. hay was eaten, but after 3 days consumption was the same as on working days. Oats and hay were of equal filling value. The gravid uterus just before foaling reduced the capacity for hay by 5 kg.

Pigs were given concentrates, potato silage and grass, with a small quantity of skimmed milk. Average intake of dry matter of the pigs, 6 months old, was 3·40 kg. per 100 kg. liveweight. The feeds were all given free choice, and about 1·1 kg. grass was eaten per 100 kg. liveweight. The total dry matter taken had 4·2 per cent. fibre. When the amount of concentrate was varied and grass was given to appetite, the intake of the latter was reduced by 0·5 to 0·75 kg. for each additional kg. concentrate. When 7-month-old pigs were given concentrates and grass to appetite they ate 4·20 kg. concentrates and 0·3 kg. grass daily, the fibre content of the dry matter being 3·7 per cent. When grass was withheld, intake of concentrates decreased. When grass and concentrates were given to appetite on alternate days, the pigs did not eat enough grass to satisfy their requirements, but took more concentrates than necessary.

LOFGREEN, G. P. and MEYER, J. H. **A method for determining total digestible nutrients in grazed forage.** *J. Dairy Sci.*, 1956, **39**, 268–273. [Dept. Animal Husb., Univ. California, Davis.]

It is suggested that when the digestibility coefficient for organic matter is known it is possible to determine total digestible nutrients by multiplying the digestion coefficient by a factor calculated from the formula $F = M(0{\cdot}01 + 0{\cdot}000125E)$, where M is the percentage organic matter in the dry matter of the feed and E is the ether extract as a percentage of the organic matter. Estimates of the digestibility of organic matter may be obtained from the formula $D = 100 - (100AY/BX)$, where D is the digestion coefficient for organic matter, A is the organic matter per g. dry matter in the faeces, B is the organic matter per g. dry matter in the forage, X is the chromogen per g. dry matter in the faeces and Y is the chromogen per g. dry matter in the forage. The validity of the formulae was confirmed by a pasture utilisation study with 18 steers.—J. N. Aitken.

5125

THOMAS, B., ROGERSON, A. and ARMSTRONG, R. H. **The influence of mineral-rich herbs on the yield and nutritive value of swards. 1. Dry matter production and composition under pasture conditions. 2. Yield, composition, digestibility and feeding value under meadow conditions.** *J. Brit. Grassland Soc.*, 1956, **11**, 10–15; 82–85. [King's Coll. (Univ. Durham), Newcastle upon Tyne.]

1. A complex grass and clover seeds mixture was sown with or without a herb seeds mixture on four ½-acre plots. The resulting swards included a 0, 7, 15 or 22 per cent. ground cover of sown herbs. There was no significant difference between plots in the liveweight gains of groups of lambs which grazed them for 6 weeks during summer. Herbage dry matter yields measured over one year fell as the proportion of herbs increased. A similar trend appeared in the data for crude protein, digestible crude protein (estimated *in vitro* by Wedemeyer's method), carotene, Fe and Mn. Lignin, Ca, P, Mg, Cu and Co contents tended to increase as the proportion of herbs rose.

2. A small area of each of the 4 plots described above was cut for hay. The presence of herbs made curing difficult. The yield of hay from the plot containing most herbs was only 57 per cent. of that from the no-herb plot. Trends in composition were similar to those described above except for the trace elements, where no differences appeared. In a trial with 2 sheep no difference was found in the digestibility of the organic matter of the 4 hays, but digestibility of crude protein fell steeply as the proportion of herbs increased. The aftermath was cut and given to guineapigs. Their mean gains in liveweight per 100 g. grass eaten or digested fell with increasing herb content.

BRUNDAGE, A. L., SWEETMAN, W. J., HODGSON, H. J. and BULA, R. J. **The utilization of smooth bromegrass (*Bromus inermis*) under rotational and strip grazing systems of pasture management. 1. Animal and pasture production.**

BRUNDAGE, A. L., SWEETMAN, W. J. and BULA, R. J. **2. Digestibility-intake studies.**

BRUNDAGE, A. L. and SWEETMAN, W. J. **3. Animal behavior.** *J. Dairy Sci.*, 1956, **39**,

280–286 ; 287–296 ; 297–302. [Dept. Animal Husb., Alaska Agric. Exp. Stat., Palmer.]

1. Two trials, in 1953 and 1954, were made in which equal areas of smooth bromegrass pastures were used for grazing dairy cattle either rotationally or by strip grazing : one half was divided into 4 for the rotation and a new strip of the other half was grazed every 24 hr. The total area was 4 acres in 1953, of a pasture seeded down 5 years previously ; the grazing period was 55 days and 4 cows were grazed on each system. In 1954, 6·4 acres seeded in 1953 were used, again with 4 cows for each system, and the period was 76 days. The cows were allocated between systems so as to be as nearly equal as possible in age, stage of lactation and milk yield. There was a slightly better utilisation of the pasture when it was strip grazed, but the difference was not significant, and under efficient rotational management there was no waste of herbage. In 1953 the cows ate somewhat less grain when strip grazing, and in 1954 considerably more. Estimated total digestible nutrients supplied per acre by the pasture were higher, but not significantly so, for the stripgrazed area.

2. One cow in each system of the 1954 trial was used in digestibility trials, during which the cows had pasture only. A combined chromogen and chromium oxide technique was employed. It was found that the milk and faeces were produced from forage eaten after the same interval of time. Under strip grazing, digestibility of the dry matter of the herbage and yield of milk were positively correlated, but this was not found under rotational grazing. Utilisation of pasture was estimated from intake and digestibility, from calculated total digestible nutrient requirements, and from clippings taken before grazing. All methods are of value, but for investigations over short periods, such as the one reported, the last two are not as good as the first.

3. During the 1953 trial observations of the grazing cows during 9 periods of 6 hr., between morning and evening milking, were made. The time spent grazing seemed to be related to the stage of maturity of the grass, especially in strip grazing. In both systems the time spent grazing increased with the season, as did the time so spent during the morning. In strip grazing the time spent grazing in the afternoon was fairly constant. but in the other system it increased. This may have been due to the greater need for more careful selection of palatable herbage unsoiled by droppings. The grazing of the rotational areas, when pasture was becoming sparser as well as less palatable, was more intense in the afternoons, and when turned on to the pasture in the morning the cows gave audible expression to their dissatisfaction, grazing intensely only when absolute necessity dictated that they should.—T. D. Bell.

PIGDEN, W. J. and BRISSON, G. J. **Effect of frequency of administration of chromic oxide on its fecal excretion pattern by grazing wethers.** *Canad. J. Agric. Sci.*, 1956, **36**, 146–155. [Canada Dept. Agric., Ottawa, Ont.]

In three 4-day field trials, each with 4 sheep, the average recoveries of Cr_2O_3 were 101 per cent. (range 95 to 108), 94 per cent. (range 89 to 106) and 87 per cent. (range 80 to 93). Individual variation in recovery was considerable whether the chromogen was administered once or twice daily.

In an 8-day trial with 2 sheep the recoveries were 100 and 102 per cent. when the chromogen was administered twice and 6 times daily, respectively.

The daily pattern of chromogen excretion measured at 2-hr. intervals was relatively constant for individual sheep but varied considerably from animal to animal. The Cr_2O_3 content of faecal grab samples taken at 2-hr. intervals throughout the day varied from 45 to 180 per cent. of the daily average with 1 dose daily and from 65 to 135 per cent. with 2 doses daily. There was no distinct excretion pattern with 6 doses daily.

The preliminary period required for average daily excretion to equal intake was 10 days.

5128

KAMEOKA, K., TAKAHASHI, S. and MORIMOTO, H. **Variation in the excretion of chromic oxide by ruminants.** *J. Dairy Sci.*, 1956, **39**, 462–467. [Nat. Inst. Agric. Sci., Chiba, Japan.]

When goats were fed at 9 a.m. and 4 p.m. on hay and concentrates containing Cr_2O_3 the pattern of chromogen excretion appeared to show only one peak concentration daily (*cf.* Absts. 1034, Vol. 23 ; 2451, Vol. 24 ; 4658, Vol. 25). The excretion pattern was similar whether hay plus concentrates or concentrates alone were given. When the animals were fed at 12-hr. intervals there appeared to be 2 peak concentrations of Cr_2O_3 in the faeces. The effect of time of feeding on faecal excretion pattern is discussed.

Daily variation of up to 10 per cent. in the concentration of Cr_2O_3 in faeces was shown to be common, and the implications of this finding are discussed.—J. Davidson.

CHARLET-LERY, G. and LEROY, A. M. Influence d'une méthode de pulvérisation à sec du son de blé sur l'utilisation digestive de cet aliment par le porc. [**Effect of a method of dry grinding of wheat bran on its digestibility by pigs.**] *Ann. Zootech.*, 1955, **4**, 333–339. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

In a digestibility trial with 3 pigs, initial liveweight 30 kg., a basal ration of barley 73, yeast 5, meatmeal 6, fishmeal 8, groundnut cake 8 and

minerals 3 per cent. was used, and a replacement of 30 per cent. wheat bran, either treated or untreated, was given. The treatment of the bran consisted in alternating periods under pressure or at reduced pressure with exposure to ultrasonic force. Experimental periods were of 12 days, with intermediate periods of 9 days. The pigs were given as much as they would clean up in 20 min. twice a day. They gained well, though with so few pigs no significance is attached to the actual gains. At the end of the experiment liveweights were from 65 to 70 kg.

Treatment of the bran increased its feeding value by 13 per cent., from 0·65 to 0·74 feed unit per kg. dry matter. Digestibility of crude protein was increased from 65 to 77 per cent., that of other constituents of the ration was increased but not significantly.—T. D. Bell.

5130

WALKER, D. M. and HEPBURN, W. R. **The nutritive value of roughages for sheep. 2. The relationship between the gross digestible energy and the chemical composition of silages.** *J. Agric. Sci.*, 1956, **47,** 172–186. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

For part 1 see Abst. 4245, Vol. 25.

2. In an 8-month study, 9 Cheviot wethers in metabolic cages were given grass silages differing widely in chemical composition. Volatile acids and bases, proximate nutrients and lignin and true cellulose were estimated. The gross digestible energy content of the silage was found to be closely related to the lignin content and was best predicted from the lignin, cellulose and crude protein contents. Metabolisable energy was closely related to digestible energy.—J. C. Gill.

ROGERSON, A. **Feeding values of local barley, maize and oat straws.** *E. African Agric. J.*, 1956, **21,** 159–160. [Joint Animal Indust. Div., E.A.A.F.R.O. and E.A.V.R.O.]

A proximate analysis of dry matter and digestibility data are given for barley, maize and oat straws. The East African straws had a higher crude protein content than British straws (Woodman, Abst. 1419, Vol. 19). The digestibility coefficients estimated with wethers were 26·1, 6·8 and 23·8, the barley straw being slightly more digestible and the oat straw less digestible than British straws. The values for starch equivalent, 21·4, 27·6 and 16·0, were lower than the British values.—A. Hepburn.

5132

TRIMBERGER, G. W., KENNEDY, W. K., TURK, K. L., LOOSLI, J. K., REID, J. T. and SLACK, S. T. **Effect of curing methods and stage of maturity upon feeding value of roughages. 1. Same levels of grain.** *Cornell Univ. Agric. Exp. Stat. Bull.* No. 910, October 1955, pp. 43.

1. Silage and hay were made from a timothy and legume crop in its first and second years. Early silage was cut in early June, barn-dried hay a week later, and late silage and field-cured hay in mid-July. In the second year the mixture had a higher proportion of grass. Yield, composition and digestibility of the 4 roughages in each year were estimated, and losses of nutrients for each method of preservation were calculated. The roughages were given to dairy cows, all of which received the same allowances of grain and concentrates, and the effect on milk yield and weight changes was studied. The carotene content of the roughages and its effect on levels of carotene and vitamin A in blood and milk of the cows were also studied.

There was a greater yield of dry matter per acre when the forage was cut later. Of this available dry matter 84·8, 84·1, 80·4 and 77·5 per cent. was available for feeding of the barn-dried hay, late silage, early silage and field-cured hay, respectively, the differences being due to shattering and loss of leaf during harvesting.

The quality and composition of the forages cut earlier were reflected in the preserved roughages, which had a higher percentage of protein, and were more palatable and digestible. The late silage was also more digestible then field-cured hay. Intakes of dry matter by the cows were higher because of the greater palatability.

Milk yield was highest on early silage, but the yield of milk per acre, when allowance was made for the grain given, and for maintenance requirements, was about the same for early silage and barn-dried hay, and these were better than the late-cut crop preserved in either way.

Carotene was higher in the earlier cuts, and was higher in the first than the second-year crop, in the latter because of the different proportion of clover. During harvesting and storage the loss of carotene was great, and in early silage 39·4, late silage 38·9, barn-cured hay 5·5, and field-cured hay 4·7 per cent. remained in the roughage as eaten. All the roughages provided more carotene than was required by the cows, but some difference was found in vitamin A and carotene content of blood plasma and milk. The advantages of the 3 methods which are least dependent on the weather, and which involve less loss in harvesting, are discussed.

BREIREM, K., HVIDSTEN, H. and HØIE, J. **Antibiotics in animal nutrition.** *Roy. Agric. Coll. Norway, Div. Animal Nutrit., Repr.* No. 152; *Div. Poultry Fur Animals, Repr.* No. 22, 1955, pp. 22.

The literature on antibiotics is briefly reviewed. Experiments with chickens, mink and foxes, pigs, calves and lambs are reported.

With chickens growth to 4 weeks of age was improved when supplements of bacitracin, aureomycin, terramycin and penicillin were given, but there was no improvement in efficiency of feed utilisation. The growth response was variable and smaller than those reported from other countries, and no constant difference was found between the different antibiotics. In one experiment efficiency as well as growth from 4 to 7 weeks of age was improved by antibiotic supplements.

Antibiotics had no effect in mink and foxes on reproduction or growth of young animals.

In 16 experiments with pigs from weaning to 90 kg. liveweight, growth response to aureomycin, penicillin and a combination of bacitracin and penicillin was obtained in most cases, but not all, and response varied greatly. The experiments were made in different environmental conditions. Efficiency was improved when growth was. Bacitracin implanted in sucking pigs had no effect.

With calves in one experiment growth from 2 days to 14 weeks of age was improved by supplements of aureomycin and penicillin, but in another, growth stimulation by penicillin ceased after 11 weeks, possibly because the antibiotic had deteriorated during storage.

Neither aureomycin by mouth nor bacitracin by implantation improved the growth rate of thrifty lambs. With unthrifty lambs a small but non-significant advantage was recorded for both treatments.

In Norway the law now permits the inclusion of penicillin, terramycin and aureomycin in commercial concentrate mixtures, but these mixtures must be available also without antibiotics. The conditions, economic and environmental, under which antibiotics are advantageous are discussed.

ROGERSON, A. **Nutritive values of locally prepared pollards and dried brewers' grains.** *E. African Agric. J.*, 1956, **21**, 161–162. [Joint Animal Indust. Div., E.A.A.F.R.O. and E.A.V.R.O.]

Except for a lower value for ether extract, pollards had a similar composition to British second grade, coarse middlings. Digestibility trials with wethers on a mixture of hay of known feeding value and pollards showed that the latter had amounts of digestible constituents similar to those of the British product except for ether extract, which was about 60 per cent. less. The starch equivalents of the local and British products are given as 63·6 and 65·5. Similar experiments showed that brewer's grains, apart from lower ether extract, were similar in composition to British samples. Both had a starch equivalent of 56·7.

5142

BLAXTER, K. L. and GRAHAM, N. M. **The effect of the grinding and cubing process on the**

utilization of the energy of dried grass. *J. Agric. Sci.*, 1956, **47**, 207–217. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

Six sheep were used in 18 trials in metabolism apparatus to investigate the energy retention from 3 different forms of the same dried grass, at 2 levels of intake. The grass was chopped, coarsely ground and cubed or finely ground and cubed, and 600 or 1500 g. daily were given. Energy retention, calculated from C and N retention and from energy exchange agreed well.

No significant difference in energy retention was found between levels of feeding or between methods of preparation. At the lower level of feeding calculated net energy of the feed was higher, but this was not of importance within the normal range of feeding, and only at very high levels would cubing show any advantage.

Faecal losses of energy and methane losses seemed to be reciprocal: with cubes the former were higher and the latter lower, and at the lower level of feeding faecal losses were less. Urine losses were not affected. Heat losses were higher at the higher level of feeding and lower with cubes. The compensatory nature of the losses in relation to the net energy of the feeds is discussed.

Digestibility of the carbohydrates of cubed was lower than of chopped grass, but it was mainly the structural material of the cells which was affected. It is suggested that this is related to the rate of passage of the feed through the intestinal tract.

T. D. Bell.

5143

BLAXTER, K. L., GRAHAM, N. M. and WAINMAN, F. W. **Some observations on the digestibility of food by sheep and on related problems.** *Brit. J. Nutrition*, 1956, **10**, 69–91. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

Finely ground cubed dried grass passed through the digestive tract of sheep more quickly than coarsely ground cubed, and coarsely ground cubed more quickly than long dried grass, and the quicker the rate of passage the less was the digestibility of the feed. Increasing the feed intake from 600 to 1500 g. daily also increased the rate of passage of the feed and decreased digestibility.

Using the results of this trial, in which 6 sheep were used in 18 tests, it was shown that in digestibility trials the length of the faecal collection period does not greatly influence the accuracy of the results. By mathematical analysis of results an equation was derived from which diurnal variation in the production of faeces could be estimated, and it was established that a preliminary period of 10 days before collection was adequate. Frequent feeding is desirable for accuracy in digestibility trials, and the importance of feeding at regular intervals was emphasised by the mathematical study. It was also shown that digestibility was closely related to and could be predicted from the rate of passage of the feed. The amount of ballast or "fill" in the gut estimated by mathematical study was found to agree well with results of slaughter trials. The effect of "fill", as influenced by the form of the feed and its digestibility, on the appetite of ruminants is discussed.

T. D. Bell.

KORMANOVSKAYA, M. A. Opyt podgotovki solomy k skarmlivaniyu. [**Prepared straw for feeding.**] *Zhivnotnovdstvo*, 1955, No. 11, 21–24.

Different methods of preparing straw for feeding are described: straw may be chopped and given as it is, or the chopped straw may be steamed or fermented in pits, or treated with a 0·5 per cent. solution of wood ash with the addition of salt, 1 per cent. of the weight of the straw. The wood ash can also be boiled, at the rate of 2 kg. ash for 50 kg. straw, in 10 litres of water, then diluted in 30 buckets of warm water; the chopped straw is soaked in this for 10 to 15 min., then spread out for 10 hr. and given to cows at the rate of 20 to 30 kg. per cow daily.—H. Scherbatoff.

5145

KOZLOVSKII, A. I. Vyvedenie novykh sortov kormovykh korneplodov. [**Production of new varieties of fodder roots.**] *Zhivotnovodstvo*, 1955, No. 10, 20–29. [Sibirsk. Nauch.-Issled. Inst. Zhivot.]

New varieties of fodder and sugar beet, turnips and fodder carrots are said to give higher yields than earlier varieties; the carrots produce 703 centners (1 centner = 50 kg.) per ha. and have an increased carotene content.—H. Scherbatoff.

5148

CHARLET-LERY, G., LEROY, A. M. and ZELTER, S. Z. (with DUMARY, C. and MARTIN, J.) Recherches sur l'efficacité alimentaire des marcs de pomme fermiers. 5. Étude chez le mouton et le porc, de la digestibilité apparente de constituants de marcs de pomme frais, ensilé ou deshydraté. [**The feeding value of cider apple residues. 5. Study with sheep and pigs of the apparent digestibility of the constituents of fresh, ensiled or dried apple residues.**] *Ann. Zootech.*, 1955, **4**, 321–332. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

For previous parts see Absts. 5330, Vol. 24; 243, 1419, Vol. 25; 1223, Vol. 26.

5. Digestibility trials with sheep and pigs are reported. The sheep, 4 mature Île-de-France of about 52 kg. liveweight, were given a basal ration of lucerne hay, and dried, ensiled or fresh cider apple residues supplying from 20 to 51 per cent. of the dry matter of the total ration. The digestibility of the organic matter of the residues was 56 per cent., regardless of whether they were dried, ensiled or fresh, which was slightly better than that of the organic matter of lucerne hay alone. Fibre of the residues was better digested than that of the hay. Protein was not digested, and gave a negative value for digestibility. The nutritive value of 1 kg. dry matter was from 0·55 to 0·62 feed unit.

Three Large White pigs of initial liveweight 26·5 kg. were given a basal ration of oat bran 20, included to give a crude fibre content similar to that of apple residues, barley 52, meatmeal 6, fishmeal 5, distiller's yeast 5, groundnut cake 8 and mineral mixture 4 per cent. The dried, ensiled or fresh residues formed from 13 to 22 per cent. of the ration. Individual differences were large. Digestibility of organic matter of the whole ration was depressed progressively by increasing amounts of residues by up to 4 per cent., although fibre was slightly better digested when the apples were included. Dried residues were better utilised than fresh or ensiled. Digestibility of organic matter was 54 per cent. As with sheep, crude protein was not digested. The nutritive value of the residues was from 0·51 to 0·60 feed unit per kg. dry matter.—T. D. Bell.

KATKOV, B. P. Znachenie kormovykh bakhchevykh kul'tur v obespechenii skota sochnymi kormami. [**Importance of gourd cultivation in providing stock with succulent fodder.**] *Zhivotnovodstvo*, 1955, No. 8, 17–23.

Pumpkin is superior to water melon in dry matter content and digestible protein. For feed units beet, pumpkins and water melons with seeds are almost equal, but pumpkins and water melons have a higher digestible protein content than beet and carrots. Pumpkins and water melons produce excellent silage, usually with the addition of chopped hay or straw.—H. Scherbatoff.

5150

TODD, J. R. **Investigations into the chemical composition and nutritive value of certain forage plants at medium altitudes in the tropics. 3. The digestibility and nutritive value of grass and legume hays and 'standing hays'.** *J. Agric. Sci.*, 1956, **47**, 225–231. [E. African Vet. Res. Organiz.]

For previous parts see Abst. 2897, Vol. 26.

3. Digestion trials are reported with sheep for 7 grass and legume hays and for 7 "standing hays", *i.e.*, dried mature grass, which forms the bulk of the ration for animals during the dry season. At the flowering stage grass hay of good quality is obtainable; more mature grasses provide hay of only poor or very poor quality. Legume hays also were good. In the "standing hay" form grasses were generally poor; *Brachiaria brizantha*, a drought-resistant species, was best. The tentative conclusion is that, in the dry season, the extensive grazing areas of East Africa are capable of providing, at the most, for maintenance requirements of ruminants.—D. Harvey.

5151

ROGERSON, A. **Nutritive value of pineapple residues (dried).** *E. African Agric. J.*, 1956, **21**, 163. [Joint Animal Indust. Div., E.A.A.F.R.O. and E.A.V.R.O.]

Unmilled pineapple residues were given with hay of known feeding value to 4 sheep. The digestibility coefficients of crude fibre and N-free extract, present as 16·22 and 74·50 per cent. of the dry matter of the pineapple, were 76·7 and 79·2, respectively, but crude protein, true protein and ether extract, present as 3·53, 2·45 and 0·50 per cent., had negative digestibility values. The starch equivalent is given as 47·9.—A. Hepburn.

5152

DIJKSTRA, N. D. De verteerbaarheid en voederwaarde van kervelzaad. [**Digestibility and feeding value of garden chervil seed.**] *Landbouwk. Tijdschr.*, 1956, **68**, 609–611. [Rijkslandbouwproefstat., Hoorn.] English summary.

Three wethers had daily 600 g. hay of known composition and digestibility and 500 g. ground seeds of chervil (*Anthriscus cerefolium*). Per 100 g. dry matter the chervil meal had crude protein 20·37, ether extract 11·10, N-free extract 31·86, crude fibre 26·09, ash 10·58 and true protein 18·76 g. Mean digestibility coefficients in that order were 64·1, 71·2, 83·6, 57·4, 58·1, 11·9 and 69·0. The seed had therefore 13·02 per cent. digestible

crude or 11·62 per cent. digestible true protein and its starch equivalent was computed to be 52·2.

I. Leitch.

5153

MAHADEVAN, V. **Nutritive value of green manure crops. 2. *Gliricidia maculata*. 3. *Phaseolus aconitifolius* or Phillipesara.** *Indian Vet. J.*, 1956, **32,** 457–462 ; 463–465. [Dept. Animal Nutrit., Madras Vet. Coll.]

For part 1 see Abst. 5762, Vol. 25.

2. The mature leaves of *Gliricidia maculata* contained, per cent. : digestible protein 10·70, digestible ether extract 1·05, digestible fibre 2·54 and N-free extract 23·44, with a starch equivalent of 39·10 and a nutritive ratio of 2 : 7. The Ca content was 2·16 and that of P 0·35 per cent. The leaves were unpalatable to cattle and contained a phenolic compound. Reports from British West Indies, Malaya and Ceylon, however, state that the leaves are palatable to stock. Guineapigs fed on the leaves in place of cabbage and beet leaves ate less and lost weight.

3. *Phaseolus aconitifolius* (*trilobus*) cut at 3-monthly intervals had an average percentage composition on a dry matter basis of crude protein 23·91 (digestible 17·26), ether extract 2·76 (1·84), crude fibre 16·57 (8·29) N-free extract 43·56 (29·10) and ash 13·02. The Ca content was 1·57 and that of P 0·50 per cent. Its feeding value was similar to that of alfalfa hay. The Ca : P ratio is unbalanced and a supplement rich in phosphorus, such as bran, should be given.—J. S. Thomson.

SHULYUMOVA, E. S., FED'KO, P. A., ZHAVORONKINA, N. S., ROZUM, YU. G. and MURANOV, B. M. Primenenie tkanevykh preparatov s tzel'yu stimulyatzii rosta i razvitiya molodnyaka. **[The use of tissue extracts to stimulate growth and development of young animals.]** *Zhivotnovodstvo*, 1956, No. 4, 66–70. [Oskhi.]

Powdered dried placenta from cattle was given to different types of livestock, including poultry. The appetite of the experimental animals increased, food absorption improved and growth rate in young animals and birds rose. Best results were obtained after a prolonged period of 2½ to 5 months. The weight of experimental pigs was greater than that of controls by from 400 to 2000 g. Each pig was given 0·5 g. daily.—H. Scherbatoff.

5157

ALIPOV, V. V. Skarmlivanie fosforitov zhivotnym. **[Rock phosphates for animal feeding.]** *Zhivotnovodstvo*, 1955, No. 11, 98–100. [Nauch.-Issled. Inst. Sel'skokhoz. Yugo-Vostoka.]

Increased liveweight in calves and better bone development were noted when they were given rock phosphate. Accumulation of fluorine in their teeth and tissues made it necessary to limit continuous use of rock phosphate in the ration to not longer than 4 months. The amount of phosphate meal should not exceed an equivalent of 1 mg. F per calf or lamb and 3 mg. F for cattle and sheep daily. The phosphate was used as a substitute for bonemeal which had to be imported from other regions.—H. Scherbatoff.

BAINTNER, K. Lehetőségek állatállományunk takarmányfehérje hiányának pótlására. **[Means of combating the protein shortage in animal feeding.]** *Rep. Fac. Animal Husb., Hung. Univ. Agric. Sci.*, 1955, **1,** No. 4, 3–20. [Inst. Animal Nutrit., Univ. Agric. Sci., Budapest.] Russian, German and English summaries.

There is great difficulty in meeting the protein requirements of livestock in Hungary. Much of the protein-rich plant produce, such as sweet lupins, is needed for human food, though by-products such as beet pulp and brewery wastes are available for animals. Means of increasing the supply of protein must be found which do not call for an increase in arable land and which are as far as possible independent of the bad climate. Urea with molasses was found to be useful to replace some protein for dairy cows of medium yield and for fattening cattle, but is not recommended for young cattle. Studies are being made with different types of yeast. Penicillin mycelium was of value in experiments with pigs and poultry, but the quantities available are trifling. (From English summary.)

SEIDLER, S. and ŻÓŁKIEWSKI, A. Żywienie koni roboczych paszami zastępczymi. [**Substitute feeding of work horses.**] *Rocz. Nauk rol.* [*B*], 1955, **69,** 381–398. Russian and English summaries.

In an experiment with working geldings 50 to 100 per cent. of the oats on which they were fed was replaced by a mixture of 1 part horse beans and 4 parts dried beet pulp or of 7 parts rye bran and 4 parts potato flakes. The maximum amounts of the mixtures were 5 kg. of the first and 5·5 kg. of the second. All the animals performed well compared with those getting oats and weight changes were similar in all groups. It was apparent that on soils and in conditions unsuitable for the growing of oats the mixtures investigated would be suitable replacements. To replace 1 kg. oats required 0·2 kg. horse beans and 0·8 kg. dried beet pulp or 0·7 kg. rye bran and 0·4 kg. potato flakes. (From English summary.)—T. D. Bell.

CATTLE

GROWTH AND FATTENING

5163

PATCHELL, M. R. **The use of dried buttermilk in a meal mixture as a feed for dairy calves.** *N.Z. J. Sci. Technol.* [*A*], 1956, **37,** 538–541. [Dairy Res. Inst. (N.Z.), Palmerston North.]

Calves were reared on whole milk for 3 weeks, and then, after a 2-week transition period, on a meal mixture containing dried buttermilk, pollard meal and either maizemeal or wheatmeal, dry or in the form of a gruel. Throughout the trial, which lasted for 10 weeks, the calves were rotationally grazed on pasture of good quality ; they were brought in for feeding twice daily and were allowed 2 hr. to eat their food. Growth rates of calves given the meals as a gruel were significantly higher than of those given the meals dry. There was no difference between results for the meal mixtures. Difficulty was experienced in coaxing the calves to eat the dry meal in the allotted time, and it is suggested that better results might have been obtained with dry meal if the calves had been allowed free access to it.—T. R. Preston.

5164

KESLER, E. M., MCCARTHY, R. D. and KNODT, C. B. **Nipple versus pail feeding of milk to Holstein calves.** *J. Dairy Sci.*, 1956, **39,** 542–546. [Dept. Dairy Sci., Pennsylvania Agric. Exp. Stat., University Park.]

Four methods of hand-feeding calves with milk were compared ; from metal pails on the floor ; metal pails 10 in. from the ground ; pails fitted with nipples and suspended so that the calf had to raise its head to suck ; 2-qt. bottles fitted with nipples and suspended at the same height as the nipple pails. The calves were given 1 gal. milk daily and water, hay and a dry calf starter to appetite.

In general, pail-fed calves took their milk much more rapidly, ate more hay and calf starter and gained in weight faster than calves fed from nipple pails or bottles.—T. R. Preston.

5165

LASSITER, C. A., SEATH, D. M., ELLIOTT, R. F. and BASTIN, G. M. **Use of distillers' grain solubles in calf starters.** *Univ. Kentucky Agric. Exp. Stat. Bull.* No. 623, March 1955, pp. 8.

Dry calf starters containing maize or milo distiller's dried solubles when given to calves reared according to a plan with limited milk were as satisfactory as a conventional starter containing dried skimmed milk. The growth rate of calves fed on starters containing rye distiller's solubles was 15 per cent. less than that of calves receiving the other starters.—T. R. Preston.

MIKHALIN, A. I. Vyrashchivanie telyat na ponizhennykh normakh tzel'nogo moloka. [**Rearing calves on a reduced allowance of whole milk.**] *Zhivotnovodstvo*, 1956, No. 1, 59–64.

Results of several experiments confirmed the findings of experiments in other countries that calves can be satisfactorily reared on reduced allowances of whole milk, supplemented by skimmed milk, concentrates and other foods of vegetable origin. It is recommended that about 150 litres of whole milk should be given during the first 4 months of life.—H. Scherbatoff.

5167

HIBBS, J. W., CONRAD, H. R., POUNDEN, W. D. and FRANK, N. **A high roughage system for raising calves based on early development of rumen function. 6. Influence of hay to grain ratio on calf performance, rumen development, and certain blood changes.** *J. Dairy Sci.*, 1956, **39**, 171–179. [Ohio Agric. Exp. Stat., Wooster.]

For previous parts see Absts. 1266, 3860, 4401, Vol. 24; 1353, Vol. 25.

6. The effects of 3 different ratios of hay to grain (4 : 1, 3 : 2, 2 : 3) and an exclusive milk diet on growth, feed consumption and feed conversion efficiency were studied in an experiment with 12 Jersey and 9 Holstein calves. Whole milk was given to one group for 12 weeks; the remaining groups received milk up to 7 weeks and hay and a grain mixture throughout. Inoculations of cud taken from older cattle were given weekly for the first 6 weeks. Calves fed exclusively on whole milk showed the best skeletal development but did not differ significantly in total liveweight gain from those given the ration with hay : grain ratio 2 : 3. Weight gain, total digestible nutrient intake, and percentage protein digested increased as the amount of grain in relation to hay increased. There was no effect of the hay : grain ratio on the total volatile fatty acid content of the rumen juice. Rumen *p*H increased and establishment of indicator rumen micro-organisms developed with age. The *p*H of the rumen juice was lower when the proportion of grain was higher. Blood glucose was not affected by the hay : grain ratio. Blood cholesterol declined after the withdrawal of milk from the diet.—J. N. Aitken.

5168

HAWKINS, G. E. (Jr.) and AUTREY, K. M. **Effects of feeding grass and of sanitation on growth of young dairy calves under two systems of management.** *J. Dairy Sci.*, 1956, **39**, 196–203. [Dept. Dairy Husb., Alabama Polytech. Inst., Auburn.]

The value of grass for calves on a basal diet o milk and concentrates and housed indoors in conventional barns or outdoors in open, portable pens on clean ground was determined in an experiment extending over 2 years and involving 36 animals. The effect of rearing calves in open pens on ground contaminated by mature cattle was investigated in the second year only.

Calves housed conventionally grew slightly faster and required less feed per lb. gain than calves in outdoor pens on clean ground. Confining calves on contaminated ground resulted in significantly poorer growth compared with those reared on clean ground. Grass had no effect on weight gains of calves in either housing group.—T. R. Preston.

5169

JONES, W. G., BARTLEY, E. E., SWENSON, M. J., UNDERBJERG, G. K. L., ATKESON, F. W. and FRYER, H. C. **Effects of supplementing a calf ration with trace minerals, aureomycin, and other dietary constituents as measured by growth and feed consumption.** *J. Dairy Sci.*, 1956, **39**, 188–195. [Dept. Dairy Husb., Kansas Agric. Exp. Stat., Manhattan.]

Three groups of 9 Holstein and Ayrshire calves of both sexes were used. During the period from birth to 24 weeks the growth rate of calves on a basal ration was compared with that of calves on the same ration supplemented with Fe, Cu, Co, I, Mn and Zn and also with the growth of calves on the basal ration plus trace minerals with added Ca, P, Mg and NaCl, vitamins A, B complex, C, D, E and K and aureomycin. The calves in both supplemented groups grew at a significantly faster rate than those given the basal ration only. Animals receiving the trace minerals showed a dmininishing rate of growth in the later stages of the experiment. At 24 weeks of age the calves receiving the mineral, vitamin and aureomycin supplement were significantly heavier than those in the other groups.—J. N. Aitken.

5170

BARTLEY, E. E., PARRISH, D. B. and WHEATCROFT, K. L. **Antibiotics in dairy cattle nutrition. 6. The effects of aureomycin feeding on the apparent digestibility of certain calf rations.** *J. Dairy Sci.*, 1956, **39**, 319–325. [Dept. Animal Husb., Kansas Agric. Exp. Stat., Manhattan.]

For part 4 see Abst. 1352, Vol. 25.

6. Twelve calves were used to study the effects of orally administered aureomycin on the apparent digestibility of 3 rations: milk only, milk plus oats and milk plus alfalfa hay. For the first trial, when the calves were 9 weeks old, aureomycin slightly increased the digestibility of the nutrients of the diet of milk only, had little effect on the

digestibility of the milk and oats diet and significantly depressed the digestibility of crude fibre in the milk and hay diet. In the second trial, when the calves were 13 weeks old, the results for the milk diet were in agreement with those for the first trial; for the milk and oats diet, however, aureomycin reduced the digestibility of the crude fibre but had little effect on this or the digestibility of any other constituent of the milk and hay diet.

Growth and efficiency of feed utilisation were improved in calves given aureomycin.

KRÜGER, L., LÜSSE, W. and SCHULZE, G. Untersuchungen auf Eineiigkeit bei männlichen Fleckviehdrillingen. 1. Die Ähnlichkeitsdiagnose nach phänotypischen und physiologischen Merkmalen. [**Tests of uniovularity in male Spotted cattle triplets. 1. Diagnosis of identity from phenotypical and physiological characteristics.**]

PIESBERGEN, H. Blutuntersuchungen bei eineiigen Rinder-Drillingen. [**Blood investigations in uniovular cattle triplets.**] *Ztschr. Tierzücht. Züchtungsbiol.*, 1956, **67**, 53–67; 68–95. [Inst. Tierzucht, Justus Liebig Hochsch., Giessen.]

1. The 3 male calves were born on 1 September 1952 and received for study a month later, when they weighed 37, 40 and 40 kg. Since no diagnosis had been made at birth, the establishment of their uniovular origin depended on similarities in phenotype, feed intake and rate of drinking, growth and blood group.

A series of photographs illustrates their similarity in appearance and resemblances in hair whorls and noseprints. The calf called Bob differed more from Axel and Cito than they did from each other.

Feed intake in all 3 followed much the same pattern, but Bob ate less than the others from the 15th to the 21st week of age and more from the 34th to the 37th week. The rate of drinking was expressed in seconds per kg. fluid. The curves for all 3 calves were more similar than those of 3 unrelated calves, but again that of Bob differed from those of the other two. Their growth curves were closely similar, so were their body measurements. When they were killed at 2 years of age measurements were made on the skull, and slight differences in those of Bob again appeared. Development of teeth was similar in all.

A feeding experiment began when the calves were 63 weeks old and lasted 26 weeks. For 2 periods of 6 weeks Axel and Cito were maintained at constant bodyweight, but they quickly caught up again with Bob. All were fed on good hay, barleymeal, bran, fishmeal and dried beet pulp. The requirements for growth from between 370 and 390 kg. to between 410 and 430 kg. rose from 146 to 208 g. digestible protein and from 1183 to 1478 starch units.

2. [Not so numbered.] All 3 calves were of the same blood group, which is considered to be almost certain evidence that they were uniovular. Studies on other blood characteristics such as cell counts, mean corpuscular Hb concentration, haemolytic resistance of red cells and serological reactions confirmed the diagnosis.—D. Duncan.

5172

GREIG, W. A. and BOYNE, A. W. **The effect of high and low planes of nutrition on the haematology of monozygous twin calves.** *J. Agric. Sci.*, 1956, **47**, 150–153. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

The Hb level in 8 pairs of 7- to 9-month-old monozygous twin heifer calves was higher for those reared on a high nutritional plane than for those reared on a low plane. The relative anaemia of the low-plane animals was due to a reduction in the size of the red cells; the Hb concentration in the cells was not affected by plane of nutrition.

T. R. Preston.

5173

KLOSTERMAN, E. W., BENTLEY, O. G., MOXON, A. L. and KUNKLE, L. E. **Relationships between level of protein, molasses, trace minerals and quality of hay in ration for fattening cattle.** *J. Animal Sci.*, 1956, **15**, 456–463. [Ohio Agric. Exp. Stat., Wooster.]

In an experiment with 12 Hereford steer calves given rations containing protein on two levels and hay of poor quality the addition of molasses or trace minerals significantly increased rate of liveweight gain. Without the supplements there was little difference in rate of liveweight gain between the calves on the different protein levels. The trace mineral supplement gave the better result with the higher level of protein. The addition of molasses was of equal benefit with both levels. It was concluded that there was little advantage in providing extra protein without added trace minerals and that molasses supplied the necessary trace minerals and also had a sparing effect on the protein requirement. A second experiment was made to study the relation between molasses, quality of hay and protein level when trace minerals were given with all rations. The differences between hay of good and poor quality and between protein levels and the interaction between quality of hay and protein level were all significant. Differences between the hays were accentuated as the protein level was reduced in the poor-hay ration. It was concluded that there is an unidentified factor in hay of good quality other than trace minerals or protein.—J. N. Aitken.

5174

MÜLLER, K. Vergleichende Untersuchungen über die Entwicklung von Jungrindern bei Offenstall- und Warmstallhaltung. [**Comparative studies of development of young cattle kept in open and in warm stalls.**] *Ztschr. Tierzücht. Zuchtungsbiol.*, 1956, **67**, 159–196. [Inst. Tierzucht., Tech. Hochsch., Munich.]

The farm where the study was made is near Munich, 500 m. above sea level and fully exposed to west and north-east winds. The annual rainfall is 700 to 750 mm., two-thirds of it in summer, and the mean annual temperature is 7·5° C. There are on the average 130 days with frost and only July and August are certain to be free of frost. There are 40 to 50 days with snowfall and about 40 days with snow cover. The experimental animals were kept in 2 open wooden sheds facing south, in unsheltered paddocks. In one shed were 7 young male cattle equivalent to 3·5 GVE [= adult cattle units], in the other 9 heifers equivalent to 6·0 GVE; in the sheds the air space per GVE was 35 and 21 c.m., respectively. As a control there were 7 (3·6 GVE) young male cattle tied up in winter in the main steading where they had 24 c.m. air space and little ventilation and the conditions were always warm. The study lasted from November 1953 to July 1954. The cattle were initially 7 months old, and some had been at pasture, others housed. They were fed on hay, silage, roots and minerals (Ramikal III). The indoor group had clean litter daily; the sheds were not cleaned but had fresh long straw daily.

In the indoor stall the air temperature varied from + 9·5° to + 17° C., in the sheds from − 4·6° to + 16·4° C., and the outdoor temperature from − 4·2° to + 14·9° C.

The animals from the sheds spent much time outside, even in the coldest weather. There was no illness. Initially 2 outdoor and 2 indoor animals gave positive tuberclin tests, but no new reactor appeared. Three animals in the open sheds had diarrhoea. The mean body temperature was, except on one occasion, lower in the indoor than in the outdoor groups, but the skin temperature was almost always higher indoors, whether it was measured above or without hair. The outdoor animals developed thicker hair coats, especially the woolly undercoat; otherwise the condition of skin and hair did not differ much.

Increase in weight was better and more even in the stall-fed cattle. From January to March the outdoor groups, especially the heifers, lost weight, but they began to catch up when they went to pasture in spring. The mean Hb values were 9·4 and 10·1 g. per 100 ml. (Hellige) in the outdoor groups and 8·3 g. in the indoor animals, and in the latter the Hb fell to little more than 7 g. in the 4 coldest months. The difference in red cell counts was less, and white cell counts were similar in all groups.

The animals in sheds needed less straw, on the average 2·75 and 3·0 kg. per GVE daily against 3·5 kg. indoors. But they wasted some hay by trampling it into the straw, and the indoor group used about a quarter less hay. The indoor group needed more labour for cleaning out and grooming, but less for feeding. The attendants disliked the open sheds because of the cold and the greater labour of carrying feed in bad weather.

D. Duncan.

5175

SPANN, J. Zur Entwicklung des Jungviehs auf Alpen. [**Development of young cattle on alps.**] *Züchtungskunde*, 1956, **28**, 229–232. [Weihenstephan.]

In 1905 and 1906 Oettle [reference not given] weighed 332 cattle of the Allgäu breed to find their gains during the alp season. He found that cattle on the highest alps gained less weight than those at lower altitude, that heifers 2 to 2½ years old grew better than other females, and bull calves better than older steers, and that the youngest animals suffered in bad weather so that it was not advisable to take them up to the alps. These results were confirmed in 1909 and 1910.

A fresh study shows that animals from the higher alps made the best growth in winter and in spring were much better than those which had not been on the alps at all. It is suggested that the improved cattle of today, such as the Swiss Brown, might give better results than were obtained earlier. It is advised that young cattle should be weighed before and after their summer on the alp, and even, if possible, during that time. Body measurements are useful also. Vitamin D production allows especially good bone formation on the high alps. A study is now in progress to compare cattle summered in a valley with those sent to alpine pasture.—D. Duncan.

5176

BUSEV, G. S. and UTKIN, V. P. Otkorm krupnogo rogatogo skota. [**Fattening cattle.**] *Zhivotnovodstvo*, 1956, No. 2, 48–53. [Vses. Nauch.-Issled. Inst. Zhivot.]

General principles are laid down for fattening beef cattle, with emphasis on homegrown fodder. Examples are given of successful methods in use on farms and experimental stations. Maize silage was particularly effective.—H. Scherbatoff.

5177

WHITING, F. **Feedlot finishing of cattle and sheep in the irrigated areas of Southern Alberta.** *Canada Dept. Agric., Ottawa, Publ.* No. 786, revised July 1955, pp. 55.

This publication is a practical guide to farmers in the irrigated areas of Southern Alberta, on all aspects of fattening cattle and sheep according to the feed lot system. It includes information on buying and selling of stock, feed lot equipment, selection and preparation of suitable feeds, and feeding and management as well as concise data on the nutritive value of the common feeds available.—T. R. Preston.

5178

FAGIOLI, A. Secondo contributo ai problemi della produzione della carne bovina di pregio con i vitelloni chianini-perugini. [**Second contribution to problems of high-class beef production with Chiana-Perugia calves.**] *Riv. Zootec.*, 1956, **29,** 143–147.

For previous part see Abst. 5808, Vol. 25.

For the second trial 8 bulls aged about 9 months, average liveweight 393 kg., fattened for 5 months to 586 kg. were studied. They required 5·15 feed units per kg. liveweight increase, compared with 5·90 feed units for the older bulls in the first trial. In spite of younger age they were considered mature at slaughter. Feed consumption per head was lower than standards recommended in the literature for fattening cattle of similar liveweight.

5179

DYER, A. J. and WEAVER, L. A. **Corn substitutes for fattening cattle.** *Univ. Missouri Agric. Exp. Stat. Bull.* No. 641, January 1955, pp. 12.

Four substitute feeds, namely, wheat, barley, molasses and rough rice were compared with maize as sources of nutrients in rations for fattening cattle.

A mixture of equal parts ground wheat and shelled maize gave slightly better results than maize alone. When only ground wheat was given as grain, digestive disorders were common and liveweight gains and resulting carcases were poor. Whole wheat proved a wasteful feed, since much of it passed through the cattle without being digested. A mixture of ground oats or maize silage with ground wheat was better than the latter given alone.

Weight gains of fattening steers were greater for rations containing barley than for those containing maize ; feed utilisation and carcase grade were similar for both grains. A mixture of barley and maize gave results for weight gain and carcase grade intermediate between those for barley and maize given alone ; feed efficiency was least for the mixture.

Molasses either in limited amounts or full-fed produced slower liveweight gains than maize. Cattle given molasses required more feed per lb. gain and their carcases, particularly those from the limited feeding regime, commanded a lower selling price.

Ground rough rice had a value equal to 75 per cent. of its weight of maize ; it was palatable, but gains and carcase grades were in favour of maize.

T. R. Preston.

5180

RIEDEL, B. B. and ARNOLD, J. L. **The effect of pasture crops with and without supplemental corn feeding and dry-lot management for beef production and nematode control.** *J. Animal Sci.*, 1956, **15,** 537–542. [Mississippi Agric. Exp. Stat., State College.]

Similar groups of Hereford, Angus and Shorthorn steers were fed in dry lot or grazed on a fescue and ladino pasture ; a fescue and ladino pasture with a maize supplement ; a ryegrass pasture ; a ryegrass pasture with a maize supplement ; a wheat pasture. The cattle were weighed at 28-day intervals, when faeces samples were collected and nematode egg counts determined. At the end of the grazing season the incidence of larvae was estimated on the pastures.

Statistical analysis of the data showed that the average daily liveweight gains of the steers grazed on the fescue and ladino clover were significantly less than those on any of the other treatments. There was improvement when the pasture was supplemented with cracked maize, but there was no reduction in the parasite egg count. Supplementation of the ryegrass pasture did not improve the rate of liveweight gain, but reduced the egg burden. The best results were obtained from the wheat pasture, which compared well with dry lot feeding in regard to liveweight gain and reduction of the number of nematode ova shed by the animal.

SWENSON, M. J., UNDERBJERG, G. K. L. and GOETSCH, D. D. **Effects of dietary trace minerals, excess calcium, and various roughages on weight gains of Hereford heifers.** *Amer. J. Vet. Res.*, 1956, **17,** 207–212. [Dept. Physiol., Sch. Vet. Med., Kansas State Coll., Manhattan.]

In 3 experiments with 36 Hereford calves, initial weight 300 to 400 lb., addition of excess Ca to a balanced basal diet adequate in P and vitamin D depressed growth over the first 6 months of the trial period. The effect was less marked after 12 months, suggesting that the calves had acquired

some tolerance to the high Ca intake. Addition of trace minerals or alfalfa hay to the basal diet had no effect on liveweight gains, although there was some indication that animals given supplements had a better hair coat, particularly when roughage of poor quality was given.—T. R. Preston.

BUTLER, O. D., REDDISH, R. L., KING, G. T. and SIMMS, R. L. **Factors contributing to the difference in dressing percentage between Hereford and Brahman × Hereford steers.** *J. Animal Sci.*, 1956, **15,** 523–528. [Texas Agric. Exp. Stat., Agric. and Mech. Coll., College Station.]

The results were based on data from 18 Hereford and 20 Hereford × Brahman steers selected at random within sire groups and split between those receiving a 35 per cent. concentrate ration and those receiving a 65 per cent. concentrate ration. At slaughter an attempt was made to account for a 2 to 3 per cent. advantage in dressing percentage in favour of the cross steers; the dressing percentages were 60·25 and 62·98, respectively, for the Herefords and crossbreds. The main items contributing to the difference were the contents and weight of the empty digestive tract of the Herefords. In a feeding trial Hereford steers made better use of a ration high in concentrates than similar steers on a low-concentrate ration. Cross steers were unaffected by the type of ration.

GARKAVI, O. V. and ERNST, L. K. Myasnye kachestva ostfrizskogo i pomesnogo molodnyaka. [**The yield of meat from young Friesian and crossbred cattle.**] *Zhivotnovodstvo*, 1956, No. 1, 30–37. [Vses. Nauch.-Issled. Inst. Zhivot.]

Crossbred cattle, Friesian × Hereford, although their liveweights were less than those of purebred Friesians, were more valuable producers of meat, since it was of higher quality than that of the Friesians. The crossbred carcases had also a much higher proportion of fat and it was better distributed than in the Friesians.—H. Scherbatoff.

5190

MÅNSSON, N. C. Vergleichende Untersuchungen hinsichtlich der Fleischleistung an Milch- und Fleischrinderrassen und ihren Kreuzungen. [**Comparative studies in beef production by milk and beef breeds of cattle and their crosses.**] *Züchtungskunde*, 1956, **28,** 168–180. [Hallands Läns Hushållningssällsk., Halmstad, Sweden.]

In 3 successive years purebred and cross calves were obtained from Aberdeen-Angus, Friesian and Swedish Red Spotted cows. The calves were of both sexes, the males castrated, and were brought to slaughter at about 18 months and 425 kg. liveweight. The Aberdeen-Angus calves were suckled by their mothers for 6 or 7 months, the other calves were reared in the usual way. All were outside for 6 or 7 months in summer and in stalls in winter.

Variations between groups tended to be greatest in winter and to disappear at pasture, after an initial fall of weight in all groups on going to pasture. For all 3 years the mean daily weight increase in g. was for Friesians 626, Aberdeen-Angus 616, Aberdeen-Angus × Friesian 605, Red Spotted 588 and Aberdeen-Angus × Red Spotted 558. The means of the first 3 groups were significantly higher than that of the last. Feed consumption, in Scandinavian feed units (F.U.) per kg. weight increase, was lowest for the Friesians and Friesian crosses; for the Aberdeen-Angus calves it was necessary to consider the feed intake of the mothers in the first 6 months, which made the mean for this group 10 F.U. per kg. against 6 to 7 F.U. for the other groups.

The losses at killing were least for the pure Aberdeen-Angus and greatest for the other pure breeds ; their carcases were of the highest quality, those of the other pure breeds were less highly classified. Meat samples from the Aberdeen-Angus carcases contained most fat, but the value of the carcases per kg. was slightly but not significantly less than that of the others.

Male animals gained slightly more weight than females and the meat from the females contained more fat. There was no significant difference in classification. Animals kept during the winter in exposed stalls gained less weight than those in proper winter quarters, but lost less in spring and were equal after a short time at pasture.

It is concluded that it would not be worth while on economic grounds to develop pure beef cattle in the dairy provinces of Sweden, since local dairy breeds can produce carcases of almost equal value and more cheaply.—D. Duncan.

DYER, A. J. and WEAVER, L. A. **Fattening comparisons : steers vs heifers.** *Univ. Missouri Agric. Exp. Stat. Bull.* No. 646, February 1955, pp. 8.

Weaned steer and heifer calves were compared under 3 fattening systems : full-fed in dry lot over the first winter and marketed at about 700 lb. liveweight ; wintered so as to gain 1·5 lb. daily and then full-fed with concentrates on pasture and marketed at 880 to 940 lb. ; wintered to gain 1 lb. daily, grazed during the summer and then full-fed in dry lot to 950 to 1100 lb.

When marketed at light weights after one winter, heifers had superior carcases which yielded more beef : although the steers made the faster and more economical weight gains, the overall advantage was with the heifers. When allowed to grow during the first winter and then full-fed on grass, heifers were fat enough to be marketed after 86 days. Continued full-feeding for a further 83 days was to the advantage of the steers, which made 25 per cent. faster gains with better feed conversion efficiency and superior carcases. When fattened in their second winter steers produced carcases of higher grade, and made faster weight gains over the preceding winter and summer as well as during the final stage of fattening. It is suggested that heifers give the best results when fed for short periods and marketed at light weights.

MILK PRODUCTION

5192

HEWITT, A. C. T. **Dairy cattle feeding trials in Kiewa Valley.** *J. Dept. Agric., Victoria,* 1956, **54,** 97–109.

On each of 3 farms, the management of which is described, cows were given either pasture and homegrown roughage, pasture, hay and crushed oats, or pasture, hay, crushed oats and linseed meal in one of the 3 years 1949–50, 1950–51, 1951–52. As a measure of production the total butterfat produced was taken, since the milk was separated and the butterfat sold to factories.

Over the whole trial it was found that the extra cost of the low-protein concentrates was not balanced by the increase in production of butterfat. With the linseed meal and crushed oats supplements increased production showed a slight profit. On the whole it was economical to keep the cows on pasture and homegrown roughage, although the total butterfat produced was less than in the other systems. Information on the yield of green feed or dry matter per acre was inaccurate.—T. D. Bell.

5193

ISAACHSEN, H., ULVESLI, O. and BREIREM, K. **Experiments in underfeeding of dairy cows.** *Acta Agric. scand.*, 1956, **6,** 3–12.

Liveweight changes, milk yields and mineral and N balances were studied in 4 cows which were underfed for the first 3 months of a lactation and then fed normally for the remainder of that lactation and for the following lactation. At each feeding level, 2 cows received roughage in the form of early-cut hay and 2 received late-cut hay. Roots and concentrates made up the diet. Underfeeding on rations which supplied only 63 per cent. of the energy, 32 per cent. of the protein and 51 per cent. of the P given normally, reduced milk yields by 45 per cent. and liveweight by 12 per cent. compared with normal feeding. Milk from the underfed cows contained less fat and protein, and was produced less efficiently in terms of production feed units (corrected for weight loss) per unit of milk produced, than milk from cows fed normally.

Early-cut hay was superior to late-cut hay, particularly during the underfeeding period.

PATERSON, R. **The milk-stimulating value of grass and its influence on animal health.** *J. Brit. Grassland Soc.*, 1956, **11**, 93–98. [Hatch Warren, Cliddesden, Basingstoke, Hants.]

The management of dairy herds of Jersey, Ayrshire and Friesian crosses from original Shorthorn stock is described. Since 1951 the use of concentrates has been gradually reduced, and in some herds is now discontinued, and the only feeds used are grass, silage and kale. The method of assessing the milk-producing value of the grass is discussed. The system of management has reduced the rate of decline of milk yield during the winter. The value of fresh grass in the spring is high, and in this respect the Italian type ryegrasses with early growth are specially valuable, though no other advantage of one seeds mixture over another in stimulating milk yield has been found. The figures reported for yield per acre and profit per acre and per cow would seem to justify the system.—T. D. Bell.

5199

SEATH, D. M., LASSITER, C. A., RUST, J. W., COLE, M. and BASTIN, G. M. **Comparative value of Kentucky bluegrass, Kentucky 31 fescue, orchard grass, and bromegrass as pastures for milk cows. 1. How kind of grass affected persistence of milk production, TDN yield and body weight.**

LASSITER, C. A., SEATH, D. M., WOODRUFF, J. W., TAYLOR, J. A. and RUST, J. W. **2. Effect of kind of grass on the dry matter and crude protein content and digestibility and intake of dry matter.** *J. Dairy Sci.*, 1956, **39**, 574–580; 581–588. [Dairy Sect., Univ. Kentucky, Lexington.]

1. Grazing trials were made over a 3-year period on eight 2-acre plots. Four duplicate plots selected at random were seeded to pure stands of Kentucky bluegrass, Kentucky 31 fescue, orchard grass and Lincoln bromegrass. All plots were given the same manurial treatments, namely, 3 dressings of 100 lb. ammonium nitrate in each grazing season. During each monthly test period comparable groups of 2 or more cows grazed each replicate of the 4 grasses. One test cow in each plot was allowed grazing alone without a supplement; the rest were given a grain supplement. The test cows were used to estimate the digestibility of the forage. Persistency of milk production was measured by calculating the ratio, as a percentage, between the production during the fourth week of the test period and the production during the week preceding the test period. The yield of total digestible nutrients (TDN) was estimated for each plot by making an allowance for yield of fat-corrected milk, body maintenance and changes in weight of the cows.

Throughout the 3 years the average persistency of milk production was 91·6, 90·8, 87·6 and 72·2 per cent., respectively, for the bluegrass, bromegrass, orchard grass and fescue. Average yearly yields of TDN per acre were 2284 for bromegrass, 2168 for bluegrass, 1749 for orchard grass and 1733 lb. for fescue. While the cows were on bluegrass and bromegrass their liveweights increased, but there was a slight loss on orchard grass and a highly significant loss on fescue.

2. The nutritional value of the grasses was estimated by the faecal chromogen and chromic oxide techniques. The dry matter content of bluegrass was significantly higher than that of the others. The average protein content of the bromegrass, orchard grass, fescue and bluegrass, respectively, was 25·6, 22·7, 21·4 and 19·2 per cent. When grazing the fescue pasture the cows tended to have a lower daily intake of dry matter. It was concluded that this was the main reason why cows on the fescue pasture showed poorer persistency in lactation, but there was a suggestion that there might be other reasons.—J. N. Aitken.

GIULIANI, R. Necessità di far pascolare le vacche da latte e di far alpeggiare i giovani bovini. [**The need to turn dairy cows out to pasture and young cattle to alpine pasture.**] *Riv. Zootec.*, 1956, **29**, 129–135.

Turning cattle out to pasture adds the benefits of sunshine, fresh air and exercise to those of the nutrients available in good grass and the saving in labour and feedingstuffs. Grazing should be regulated according to the pasture. At the outset limited grazing should be allowed to avoid bloat. Excessive grazing, and grazing when the ground is too wet, should be avoided to save the pasture. In some localities there are difficulties in grazing, *e.g.*, in vineyards, but even there 2 months' grazing after the crop has been harvested is possible.

Young stock reared on alpine pastures are sturdier and better developed than their counterparts reared indoors. Where available such pastures should be used, and are suitable for calves over 6

months old. Bulls can also be maintained on them. The pastures must be accessible and provide good grazing, with hay for emergencies, an adequate water supply, and shelters should the weather be inclement. Calves to be sent to the alpine pastures should be prepared beforehand by moving them to open sheds and accustoming them to eating off the ground. To maintain alpine pastures in good condition they must be fertilised with artificial as well as natural manures, and overgrazing must be avoided by not overstocking and by moving the herds.—T. D. Bell.

Vik, E. Samanlikning mellom berre dagbeiting med døgerbeiting for mjølkekyr. [**Comparison between grazing during the day only and day and night grazing for dairy cows.**] *Forskning og Forsøk Landbruket*, 1956, **7**, 109–128. [Beiteforsøksgarden Apelsvoll.] English summary.

Experiments were made, one in spring and one in autumn 1944 and one in 1946 that covered most of the summer; those took account only of milk yield and changes in weight of the cows. From 1950 experiments were continued and measurements were made of grass eaten and of grazing habits: in 1952 digestibility tests were made with wethers. Groups of 5 cows were matched for age, with a wide range of ages, and for stage of lactation; one grazed day and night, the other from 7.15 a.m. to 3.30 p.m. They were moved to fresh pasture every second day. Cows with restricted time to graze gave on the average nearly 1 kg. 4 per cent. milk less than those that grazed day and night, but when they were later allowed out all night the fall of milk yield with progress of lactation was arrested and their yield equalled or might exceed slightly that of the original day-and-night grazers.

Estimates of grass eaten were made with Cr_2O_3 as indicator. On the average, day-and-night cows ate 85 kg. with 16·8 kg. dry matter and day grazers 68 kg. with 13·8 kg. dry matter. When requirements were assessed by Hansson's method, both lots had an excess, and in one year day-grazers ate more than those that ate day and night. This is explained by the greater assiduity of the day cows, which grazed for 75 per cent. of the time on grass; day-and-night cows grazed for only 40 per cent. of the time. On the first day on a fresh strip of grass, day cows grazed for 75 per cent. and on the second day for 98 per cent. of the time devoted to grazing by the unrestricted group.

Seath, D. M., Lassiter, C. A., Davis, C. L., Rust, J. W. and Cole, M. **The supplemental value of alfalfa hay when fed to cows on pasture.** *J. Dairy Sci.*, 1956, **39**, 274–279. [Kentucky Agric. Exp. Stat., Lexington.]

A trial with 16 cows, 8 Holsteins and 8 Jerseys, was made in order to determine the effect of supplementing a bluegrass pasture by giving one of each pair all the alfalfa hay it would eat during each of two 2-hr. periods daily. A grain mixture was given to all cows according to production. Digestibility trials and measures of dry matter intake were made on all cows every 2 weeks by a combination of the faecal chromogen and chromic oxide techniques. There was no significant effect on milk production due to the supplement except that for a short period the cows receiving the hay produced more 4 per cent. fat-corrected milk. The animals getting hay gained significantly more in liveweight. The total dry matter intakes of the cows receiving hay increased, but there was a decrease in the amount of dry matter obtained from pasture.—J. N. Aitken.

5203

Cox, C. P., Foot, A. S., Hosking, Z. D., Line, C. and Rowland, S. J. **The direct evaluation of pasture in terms of the milk production of individually grazed cows.** *J. Brit. Grassland Soc.*, 1956, **11**, 107–118. [Nat. Inst. Res. Dairying, Univ. Reading.]

Sixteen milking cows were strip grazed in individual cow-plots on a ryegrass and clover ley for 3 weeks. Their herbage consumption during 24-hr. periods was estimated on 9 occasions from the difference between the weight of grass offered for grazing and the ungrazed residue. The precision of this method is examined and suggestions are made for improving the technique. The estimated dry matter intakes and fresh herbage intakes over the 3-week period were both found to bear a significant linear relationship to mean milk yield. It is concluded that pastures can be evaluated directly in terms of milk production by using the techniques described. The number of animals required to detect differences of various magnitudes between 2 pastures in terms of milk yield have been calculated. A multiple regression equation was calculated relating dry matter intake to yield of 4 per cent. fat-corrected milk, liveweight and liveweight increase. From this equation the maintenance requirement of a grazing dairy cow weighing 1000 lb. was estimated to be 11·7 lb. dry matter daily. The requirement for 1 lb. of 4 per cent. fat-corrected milk was 0·29 lb. dry matter and for 1 lb. of liveweight increase 2·11 lb.—J. L. Corbett.

5204

Reid, D. and Holmes, W. **Winter feeding of dairy cows. 3. The influence on milk yield of high and low protein concentrates, each fed**

at two levels in addition to dried grass and grass silage. *J. Dairy Res.*, 1956, **23,** 159–168. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

For previous parts see Abst. 3849, Vol. 26.

3. Two groups of 4 cows were allocated each to one of 4 feed supplements according to a balanced Latin square design, the supplements being 4 lb. high-protein concentrate, 4 lb. low-protein concentrate, 2 lb. high-protein concentrate, and 2 lb. low-protein concentrate per gal. All cows were given dried grass and silage to appetite. The length of time on each supplement was 4 weeks.

Cows given 2 lb. concentrates per gal. milk daily consumed 2 lb. less total dry matter, but 4·3 lb. more dry matter as grass products produced 1·2 lb. less milk (mean yield for all cows, 33 lb. daily) and gave an increased margin of milk value over feed costs of 12 pence, as compared with cows given concentrates at 4 lb. per gal. The protein content of the concentrate did not noticeably affect dry matter consumption, milk yield or profit margin. It is considered that the saving in feed costs by giving concentrates at the 2 lb. per gal. level more than compensated for the slightly reduced milk yield.—T. R. Preston.

WITT, M. Über den Einfluss verschiedener Beifuttermittel auf den Fettgehalt der Milch bei Weidegang. [**Effect of different supplements on the fat content of milk during the grazing season.**] *Arch. Tierernährung*, 1956, **6,** 61–91. [Max Planck Inst. Tierzucht, Mariensee, Trenthorst.]

A full account, with experimental details and tables and graphs of the results, is given of several experiments, some at Hanover and some at Lübeck, mostly with Black Pied Holstein cows, in which unsuccessful attempts were made to prevent the fat content of the milk falling when the cows went out to pasture, by giving supplements rich in carbohydrate or protein, *e.g.*, dried beet slices, GK-beet [not further described], or a mixture of groundnut meal and soya bean meal. The main findings have already appeared (Absts. 3044, Vol. 22; 4313, Vol. 25; 3846, Vol. 26). Some other small-scale experiments are included. The results were as before. Even a daily supplement of 2 kg. expeller process coconut meal, containing 15 per cent. crude fat, failed to prevent a fall; and it was found also when high-yieldihg cows were stall fed according to yield and let out on grass for 5 hr. daily.

There was no change in the consistency of the faeces of cows given a high-protein supplement, either in stall or at pasture. Hence it was concluded that scouring on young grass is not due to its high protein content, but may be due to its lack of fibre and high moisture content.—W. M. Deans.

COLOVOS, N. F., KEENER, H. A., DAVIS, H. A., MORROW, K. S. and GIBSON, K. S. **The effect of texture on the nutritive value of concentrates for dairy cattle.** *New Hampshire Agric. Exp. Stat. Bull.* No. 419, May 1955, pp. 11.

Dairy heifers and mature cows were used in a series of double reversal trials. A concentrate mixture of maize, crimped [crushed] oats, wheat bran, soya bean oilmeal, brewer's grains, linseed oilmeal and minerals was supplied in a fine, coarse, or very coarse meal, or pelleted. The results showed that the finely ground was superior in nutritive value in terms of digestible protein and total digestible nutrients. In tests with single ingredients ground maize was superior to flaked maize and crimped oats were generally better than ground oats, except for the digestibility coefficients for protein and ether extract. Feed consumption, milk and butterfat production and liveweight gains of cows on the fine and coarse concentrate mixtures were studied in another experiment. There was no significant difference which could be attributed to the texture of the feed except that cows on the finely ground mixture made higher liveweight gains than those on the coarse mixture.—J. N. Aitken.

5208

BARBER, D. C., CARTER, E. S. and GILES, A. K. **Do bulk foods produce milk?** *Agriculture, J. Minist. Agric. Engl.*, 1956, **63,** 61–64. [Nat. Agric. Advisory Serv., South-Western Province.]

On the assumption that 4 lb. concentrates will produce one gal. milk, data assembled from 30 Gloucestershire farms showed that the proportion of total milk produced from bulky foods such as grass, silage, hay and roots was 65 per cent. in May, 54 per cent. in July and zero in November and March. The average level of concentrate feeding over the year was 2·9 lb. per gal. milk produced, and the average daily production from each cow 2½ gal. These figures are compared with those of 20 years ago when, with semi-derelict grasslands, concentrate feeding was nevertheless at the same level of 3 lb. per gal. milk produced. It is suggested that present-day large-scale investment in production of home-grown feed is not necessarily being repaid in more economic milk production.—T. R. Preston.

5209

BLACKETT, G. and RAVELL, J. **Fodder beet or swedes for milk?** *Scot. Agric.*, 1956, **35**, 219–221. [N. Scotland Coll. Agric.]

In a trial to compare swedes with 2 varieties of fodder beet, 4 groups of Ayrshires, each of 4 cows, were used. All groups were given the same ration of hay 7 lb., grass silage 42 lb., draff [wet distiller's grains] 7 lb. and either 56 lb. Danestone swedes, dry matter 11·13 per cent., or 30 lb. Red Otofte or Pajbjerg Rex fodder beet, dry matter 20·80 and 21·08 per cent., respectively. Concentrates were given at 4 lb. per gal. over the first 1½ gal. Group 1 had the swedes for 20 days, followed by a 3-day period for changing over, then Red Otofte fodder beet for 20 days. Group 2 had the fodder beet first and the swedes second. Groups 3 and 4 were similarly treated except that Pajbjerg Rex beets were used instead of Red Otofte.

Milk yields were better, and liveweights were better maintained on swedes, but there was no significant difference in total butterfat production, although the percentage of butterfat tended to be higher with the fodder beets.

Investigations on dry matter yield per acre of the crops and reliability of crops are in progress.

T. D. Bell.

5210

BREIREM, K. **Home-grown feeds in the feeding of cattle.** *Royal Agric. Coll. Norway, Div. Animal Nutrition*, 1955, Repr. No. 139, pp. 41.

The literature on feeding standards is reviewed, and it is concluded that the use of starch equivalents or Scandinavian feed units is justified. The standards based on the latter are most convenient for dairy cows, and it is shown that deviation from them is of no advantage. Milk yields up to 2 gal. daily can be achieved without concentrates when good quality hay and silage and roots are used. Above this yield increasing amounts of concentrates are necessary.

For beef production concentrates are not needed except when products of special quality are required for the luxury market, and then only for the young growing stock.

The importance of considering the energy concentration of home-grown forages, since the dry matter intake of cattle is limited, the protein requirements and possible mineral deficiencies, when balancing rations, and the role of fat and quality of protein from different sources, are discussed.—T. D. Bell.

BROUWER, E. Variaties in de voedende bestanddelen der melk door factoren zoals lactatiestadium, voeding en erfelijkheid. [**Variation in the nutritive components of milk due to influences such as stage of lactation, diet and heredity.**] *Voeding*, 1956, **17,** 163–168. [Lab. Physiol. Dieren, Landbouwhogesch. Wageningen.]

More attention has been given to fat than to other components of milk. Apart from severe underfeeding, which may greatly reduce the solids-not-fat of milk, the biggest differences are referable to breed. Fat, fat-free dry matter, protein and riboflavin have been found, in most studies, to increase in the following order : Friesian, Ayrshire, Shorthorn, Guernsey and Jersey. Selection may modify this trend in that selection for yield without attention to fat and protein may reduce the average percentage of these constituents. On the other hand, the average may be raised by selection for more than one constituent.

MAYHEAD, J. W. and BARNICOAT, C. R. **Variations in iodine value of milk fats.** *J. Dairy Res.*, 1956, **23,** 238–247. [Dept. Biochem., Massey Agric. Coll. (Univ. New Zealand), Palmerston North.]

The cows had liberal all-the-year round grazing, some meal in addition, and were milked at 5 a.m. and 4 p.m.

Iodine value of milk fat from butter churned from combined morning and evening milk was estimated by the method of Wijs 11 times during a 16-month period beginning 2 months after (winter) calving, for 5 Friesians and 5 Jerseys at the same stage of lactation. On the average the iodine value was lower by 2·2 units for Jersey milk fat than for Friesian. Iodine value was lowest in summer (December) and highest in winter, average difference 5·4 units for Jerseys and 7·6 for Friesians.

A group of 6 Jersey cows showed persistent individual variations of almost 5 units. On the average the iodine value was 1·8 units lower in the morning than in the evening. There were also irregular day-to-day fluctuations.

In feeding experiments, cows in the later stage of lactation were given peanut oil, iodine value 96·2, calculated composition oleic acid 44·5, linoleic acid 31 and saturated acids 19·5 per cent., mixed with the meal or as a drench, in amounts of the order of the amounts of triglyceride normally ingested in herbage.

In a 16-day experiment 3 Jerseys were controls and 3 were given 8 oz. peanut oil daily in the morning for 7 days beginning on the third day. The iodine value of the milk fat soon rose significantly ; the average maximum difference, 5 to 7 days later, was 4·4 units. Milk yield was unaffected.

In the middle of a 15-day period, 2 or 4 Friesians were deprived for 36 hr. of grass but not of water and were given a maintenance ration of hay and concentrates. Partial inanition raised the iodine value by 5·7 units on the average. In another Friesian similarly deprived but getting 16 oz. peanut oil daily, half at each milking, the rise during partial inanition was only 2·3 units. This last result was unexpected, and does not agree with the idea that the rise in iodine value of milk fat from cows on a low plane of nutrition is due to increased utilisation of body fat reserves. On certain assumptions it was calculated that about a third of the long-chain unsaturated acids of the diet were converted into milk fat, and that from 30 to 60 per cent. of the unsaturated acids in the milk fat came from the peanut oil.

From results of this laboratory and those of Sears and colleagues (Absts. 1941, 3535, Vol. 13) on the composition of New Zealand ryegrass-clover pasture, it was concluded that the amounts eaten would supply at least 12 oz. daily of C_{18} unsaturated fatty acids and that this could influence both composition and yield of milk fat.—W. M. Deans.

LARSON, B. L., RÒLLERI, G. D. and KENDALL, K. A. **Protein production in the bovine. Comparison of daily protein, fat, and milk production during the entire lactation period.** *J. Dairy Sci.*, 1956, **39,** 204–213. [Lab. Biochem., Dept. Dairy Sci., Univ. Illinois, Urbana.]

In a preliminary study with 2 heifers and 2 cows it was found that maximum total protein production in milk occurred within a few days of parturition and then declined during lactation. The percentage of protein decreased as milk yield

increased but this tendency was reversed as total milk yield declined. No close relation between the protein and the fat content of the milk was shown.—J. N. Aitken.

BAINTNER, K., TÓTH, P. and KOVÁCS, L. A nyers szójabab etetésének hatása a tehenek tejtermelésére és a tej összetételére. [**The effect of feeding cows on raw soya beans on the yield and composition of the milk.**] *Rep. Fac. Animal Husb., Hung. Univ. Agric. Sci.*, 1955, **1**, No. 5, 21–32. [Inst. Animal Nutrit., Univ. Agric. Sci., Budapest.] Russian, German and English summaries.

An experiment with 8 dairy cows lasted 71 days and was divided into 3 main periods and 2 periods of adaptation. The ration in the 3 main periods included 2·5 and 5·5 kg. raw soya beans and none. With from 5 to 5·5 kg. soya beans daily, no ill effect was found, but larger amounts were found to cause diarrhoea. The milk yield was increased slightly and the fat content by 10 to 15 per cent. with 2·5 kg. soya beans, and there was no further increase with the larger quantity. The butterfat was softer, but there was no adverse effect on flavour. (From English summary.)—D. Duncan.

BRUNE, H. and SIECK, K. H. Ist die Calciumversorgung der Milchkühe durch den Oxalsäuregehalt der Futtermittel in Zuckerrübenbau-Betrieben gefährdet? [**Is the calcium supply of milk cows endangered by the oxalic acid of feeds on sugar-beet farms?**] *Ztschr. Tierernährung Futtermittelk.*, 1956, **11**, 113–126. [Inst. Tierphysiol., Univ. Göttingen.] English summary.

For previous work see Abst. 1167, Vol. 26.

Feeds were analysed for a year on 5 farms which used a lot of sugar-beet products. Each herd consisted of 19 to 22 Friesian cows, mainly fed indoors. Estimates of sufficiency of Ca and P were based on daily maintenance requirements of 30 and 20 g., with 2·5 and 2 g. per kg. milk and 3·2 and 2 g. daily for production of a calf. Available Ca in the ration was calculated by subtracting Ca, equivalent to the oxalic acid present, from the total Ca.

Results are given separately for each herd. It was concluded that although the Ca supply might be relatively poor during the short period of the year when fresh beet leaves were given, this was compensated during the rest of the year. Oxalic acid was not thought to produce Ca deficiency with the usual rations. The P supply was on the average from 6 to 12·7 g. too low. More use of P-rich milling by-products is recommended.

RICHTER, K. and OSLAGE, H. J. Untersuchungen über die Mineralstoffversorgung von Milchkühen unter verschiedenen Fütterungsbedingungen. [**Providing milk cows with minerals under different conditions of feeding.**] *Züchtungskunde*, 1956, **28**, 148–168. [Inst. Tierernährung, Brunswick, Völkenrode.]

The feeding practice was studied for several years in 7 dairy herds in north-west Germany. The farms lay on soils of different types and had different systems. Ca, Mg, P, K, Na, Cl, Fe, Cu, Mn and Co were estimated in feedingstuffs. The estimated intakes are given in tables and are also expressed as percentages of the calculated requirements.

On all the farms the Ca supply at pasture was enough for up to 20 kg. milk daily, and in winter hay, roots and silage supplied enough for 15 kg. milk, but when beet leaves were given fresh or as silage their oxalic acid content made a Ca supplement desirable. The P supply was often insufficient both at pasture and indoors, except when the intake of concentrates was fairly high. In 2 herds the Na supply in pasture was low There was always enough Mg, K, Cl, Fe, Cu and Mn. Co was sometimes deficient in pasture on peat soils and more so when winter feeding was mainly on hay and roots, but beet leaves fresh or ensiled were a good source of Co.—D. Duncan.

5224

BINNERTS, W. T. Het jodiumgehalte van melk. [**The iodine content of milk.**] *Thesis, Univ. Amsterdam*, 1956, pp. 153. English summary.

Before 1914 the occurrence of goitre in the Netherlands was considered to be negligible. Medical examination of recruits revealed that this was not so, and tests and surveys led many local authorities to add iodine to drinking water. This was stopped by the second world war, and many reports and studies have been lost. Since the war it has been established that very few regions are completely goitre-free and gradually more and more local authorities have made compulsory addition of I to salt used in baking bread. Water is no longer iodised, but it seems desirable to find additional means of supplying I. Milk might be one, and addition to milk would especially benefit expectant and nursing mothers and young children. Since the war enlarged thyroid glands have been seen in cows. While concentrate cattle feeds were still rationed, addition of I was made compulsory; now it is merely recommended. In some regions salt licks containing I are in use. Surveys of the I content of milk in several different countries yield widely different results, but seem to point to low I content of milk in goitre regions.

Experiments with groups of 6 and 12 cows showed that of 100 mg. I added to the food about 10 per cent. appeared in the milk. Iodine was estimated by a modification of the method of Sandell and Kolthoff, with cerium as catalyst, adapted for serial work (see Abst. 2771, Vol. 24). The thesis contains a detailed description of the method in English. A negligible amount of I occurs in the fatty components of milk; practically all the I is found in the milk serum and the proteins. In the same herd 31 cows of approximately the same age and stage of lactation showed I contents ranging from 0·5 to 6·6 μg. per 100 ml. Iodine content increased as milk yield decreased. Colostrum from 2 cows showed values of 2·7 and 5·9 μg. Two small herds of 8 and 6 cows on adjoining farms were tested in winter and in summer; one herd was given pump water, poor in I, about 3 μg. per litre, and the other tap water containing about 30 μg. Results were inconclusive but there was a suggestion of higher values in winter, and in the herd receiving water rich in I.

Milk from 200 creameries all over the country was tested. Maps show the location of the creameries and indicate whether the soil of the area is rich or poor in I. Values found in winter were up to 13 μg. per 100 ml. and 2·3 μg. higher than those in summer. It is argued that values of 1·3 μg. per 100 ml. or less, in August, are too low from the point of view of public health; in winter they should not fall below 3·0 μg. per 100 ml. In most regions, therefore, addition of 5 mg. daily to the feeds is desirable, which means that the I content of the concentrates should be 1 mg. per kg., about 5 times the present value. It should not be given as iodide, as that is rapidly lost.—M. Eddison.

VOLCANI, R., RODERIG, C. and OLOMUTSKI, E. **The effect of ethylene dibromide fumigated grain on cattle.** *Refuah Vet.*, 1955, **12,** 70–75 in Hebrew; 104–103 in English. [Agric. Res. Stat., Rehovot.]

Three cows and a calf 6 months old were given 50 p.p.m. ethylene dibromide in their concentrate ration. After 4 months the calf died, and post-mortem findings are described, but, on the evidence, death could not be attributed to bromine poisoning. No serious effect of ethylene dibromide on the reproduction of the cows was observed, though the period from parturition to first oestrus was longer than in untreated controls. The calf of one of the cows died after 10 days' suckling. The other 2 did not suckle, and developed normally. The milk yield and butterfat percentage of experimental cows were not affected by the treatment, but the Br content of their blood was higher than that of controls, and their milk contained Br, which was not present in that of untreated animals. The calves which died had received about 1 mg. Br per kg. bodyweight, which has been reported as toxic to poultry, and this, and the toxic forms of Br, are discussed.—T. D. Bell.

5226

SUNDARESAN, D. **Effect of milking by machine on rate of milking, yield and fat per cent. of milk of dairy cows.** *Indian J. Dairy Sci.*, 1956, **9,** 1–8. [Allahabad Agric. Inst.]

Two groups of 6 Red Sindhi cows were milked by hand and by machine in alternate weeks during a period of 2 months. There was no difference in milking time between hand- and machine-milking when the individual milking times for each cow were considered separately. The main advantage of the machine lay in the fact that it could milk 2 cows simultaneously. Total milk production and butterfat content of the milk were unaffected by the method of milking.—J. N. Aitken.

NEHLER, G. M. Untersuchungen über den Herdenumtrieb und die Nutzungsdauer in der Rinderhaltung unter Berücksichtigung der Milch- und Fleischleistung und die züchterischen Konsequenzen. [**Herd turnover and productive life in cattle with reference to yields of milk and meat and the implications for breeding.**] *Ztschr. Tierzücht. Züchtungsbiol.*, 1956, **67,** 105–146. [Inst. Tierzucht, Christian Albrechts Univ., Kiel.]

In all types of cattle the best rate of turnover of herds depends on the optimum period of milk production. When yields are set against rearing costs the maximum crude income is attained between the sixth and the eighth lactations, and with increasing yield the peak shifts towards the eighth lactation. The higher the income from milk relative to costs of meat and of maintenance, the clearer is this tendency.

Crude income rises with increase in milk and fat yield per cow and lactation and with increased length of productive life. Differential milk prices have no influence on the economically optimum productive life. The influences of meat yield and price are slight. The longer the turnover time in a herd the more economical the utilisation of feed, which also improves with milk yield.

Losses depend greatly on the resistance of cattle to environmental conditions and to the strain of high production.—D. Duncan.

5228

VENGE, O. **Genetic differences in feed utilization in dairy cattle.** *Ztschr. Tierzücht. Zuchtüngsbiol.*, 1956, **67,** 147–158. [Inst. Animal

Breeding, Royal Agric. Coll., Upsala.] German summary.

A statistical study is presented of the data in the report of Johansson (Abst. 2921, Vol. 25). It is shown that so much environmental variation was present that genetic differences made up only a small proportion of the total variation in utilisation of feed units per kg. butterfat produced. Nevertheless, genetic differences in this ability could be demonstrated between groups of daughters of different bulls, and the heritability of the ability to utilise production feed units per kg. butterfat was 0·2. Elimination of some of the complicating environmental differences is discussed.

LAMBOURNE, L. J. **A comparison between rotational grazing and set stocking for fat-lamb production.** *N.Z. J. Sci. Technol.* [*A*], 1956, **37,** 555–568. [Ruakura Animal Res. Stat., Dept. Agric., Hamilton.]

In the first of 3 trials with Romney ewes 150 were kept on one pasture all the time (set-stocked) and 150 rotationally grazed from lambing to weaning, both at the rate of 6 ewes per acre. In the second trial 75 of the ewes were set-stocked and 75 rotationally grazed at the rate of 8 per acre and in the third trial 150, similarly divided, at the rate of 4 per acre. There was no significant difference between liveweight gain or fleece weight of ewes on the 2 different stocking systems. On the rotational system, lamb weight gains were superior with 8 ewes per acre but inferior with 4 ewes or 6 ewes (normal stocking) per acre. More feed was available on the rotational system, but unless this was used by increased stocking or by conservation of the extra herbage poorer lamb growth resulted owing to a decline in the feed quality.—J. C. Gill.

5232

NEALE, P. E. **Alfalfa cube mixtures for fattening lambs.** *New Mexico Agric. Exp. Stat. Bull.* No. 398, June 1955, pp. 10.

In a comparison of 3 cubed mixtures for fattening light and heavy lambs, heavy lambs fed on cubes containing coarse alfalfa hay 70, sorghum grain 20 and molasses 10 per cent. made higher liveweight gains and were more efficient than lambs fed on the same constituents in the proportions 60 : 30 : 10 and 50 : 40 : 10. Light lambs fed on the 70 : 20 : 10 ration were almost equal to those on the 60 : 30 : 10 cubes and superior to those on the 50 : 40 : 10 cubes. Best results from these self-fed cubed mixtures were obtained when crude fibre was 15 to 20, N-free extract 48 to 50 and total digestible nutrients below 60 per cent. Highest efficiency was reached at a roughage : concentrate ratio of 73 : 27.—J. C. Gill.

5233

LIGHT, M. R., DINUSSON, W. E., RICHARD, R. M. and BOLIN, D. W. **Urea and stilbestrol for fattening lambs.** *J. Animal Sci.*, 1956, **15,** 570–574. [N. Dakota Agric. Exp. Stat., Fargo.]

In a 10-week trial with 72 feeder lambs those given soya bean oilmeal as a protein supplement made significantly greater gains than those given urea. Stilboestrol, 0·5, 1·0 and 2·0 mg. daily, gave significantly greater gains on both types of ration. Stilboestrol treatment did not affect carcase grade or yield and caused no noticeable ill effect in the lambs.—J. C. Gill.

5234

ALBERT, W. W., GARRIGUS, U. S., FORBES, R. M. and NORTON, H. W. **The sulfur requirement of growing-fattening lambs in terms of methionine, sodium sulfate, and elemental sulfur.** *J. Animal Sci.*, 1956, **15,** 559–569. [Dept. Animal Sci., Illinois Agric. Exp. Stat., Urbana.]

In a 56-day trial 15 groups, each of 3 growing and fattening lambs, were individually fed on a purified ration in which urea made up 92 per cent. of the N content. To each group ration was added methionine, sodium sulphate or elemental sulphur at 1 of 5 levels. From the liveweight gains the percentage requirement of S was : as methionine 0·64 $\pm$ 0·048, sodium sulphate 1·27 $\pm$ 0·44 and elemental sulphur 0·47 $\pm$ 0·028, supplying S 0·138, 0·29 and 0·47 per cent. of the ration, respectively. The results seem to show that sodium sulphate may be used more efficiently than elemental sulphur.—J. C. Gill.

5235

ANDREWS, F. N., STOB, M., PERRY, T. W. and BEESON, W. M. **The effect of oral and subcutaneous estrogen and androgen administration on growth and carcass quality of lambs.** *J. Animal Sci.*, 1956, **15,** 575–588. [Dept. Animal Husb., Purdue Univ. Agric. Exp. Stat., Lafayette, Ind.]

Sixteen groups of 12 feeder lambs were used in a 73-day trial in which liveweight gain was significantly increased by subcutaneous implantation of 10 mg. oestradiol plus 250 mg. progesterone or by 12 mg. diethylstilboestrol, and significantly increased by 4 mg. dienoestrol given daily by mouth. Feed efficiency was also greatly increased ($P < 0{\cdot}01$); 2 mg. dienoestrol did not improve gain significantly but improved feed efficiency ($P < 0{\cdot}05$). Two mg. dienoestrol plus 25 mg. methyl testosterone given by mouth also improved feed efficiency. Diethylstilboestrol, dienoestrol and oestradiol all caused mammary development. Difference between liveweight and cold carcase weight was greatest in lambs implanted with oestradiol and progesterone pellets, followed by lambs given 4 mg. dienoestrol daily and then by those implanted with 12 mg. diethylstilboestrol. Carcase grades of some of the treated lambs were lower than those of controls. There was little difference in the oestrogenic activity of the meat of the treated lambs and that of the controls.

J. C. Gill.

5236

MAYBEE, H. J. **Lamb and mutton grading in Canada.** *Canada Dept. Agric., Ottawa, Publ.* No. 963, December 1955, pp. 14.

The method of classification of lamb and mutton, determination of age, class and sex of carcases, and grading standards and procedures are described. Lamb carcases had smaller and softer bones, lighter coloured flesh and softer and whiter fat than ewe carcases, and up to 14 months of age had a rough break joint where the fore-feet were separated from the carcase, compared with a smooth spool-like joint in mature sheep. Details of calculation of dressing percentages and prices are presented and photographs are included to illustrate different carcase grades.—J. C. Gill.

ROBERTS, E. M., MURRAY, P. F. and BARNICOAT, C. R. **Note on the autumn decline in liveweights of grazing ewes.** *N.Z. J. Sci. Technol.* [*A*], 1956, **37,** 606–609. [Dept. Biochem., Massey Agric. Coll., Palmerston North.]

Breed differences, stage of reproductive cycle, plane of nutrition and previous nutritional status were not related to autumn liveweight losses of ewes on ample pasture. It is suggested that losses are related to variations in the quality of the pasture.—J. C. Gill.

5241

KRÜGER, L. Die deutsche Schafzucht und ihre Leistungen auf der Ausstellung in München 1955. [**Sheep rearing in Germany and its performance at the exhibition in Munich, 1955.**] *Arb. Deutsch. landwirtsch. Gesellsch.*, 1956, **31,** 50–67. [Giessen.]

The intensification of crop production has reduced the crop area available for sheep but has increased yield per unit area. Competition against arable farming and cattle has promoted selection in sheep to produce more valuable flocks yielding better fleeces and meat and more lambs. Fertility is high; on the average 95 per cent. of ewes bred become pregnant where feed allows, and twins, and in "Marsch" sheep triplets, are common. The numbers of lambs and the numbers of lambings of old and young sheep of different breeds are tabulated. Data on weights and measurements and wool yields are tabulated also.

The best German sheep are fertile, productive, good converters of feed and adaptable. The main problem is the feed supply. In South Germany, where the sheep area is specially reduced, "capacity to hunger" has become important.—F. C. Aitken.

5242

NESENI, R., ALTENKIRCH, W. and OTTO, E. Über die Beeinflussung der Geschlechtstätigkeit bei Schafen durch Zufütterung von Kobalt, Thomasmehl und Kupferschlacke. [**Effect on reproduction in sheep of supplements of cobalt, basic slag and copper slag.**] *Arch. Tierernährung*, 1956, **6,** 104–109. [Inst. Tierzuchtforsch., Deutsch. Akad. Landwirtsch., Berlin.]

For the cobalt study a flock of ewes was divided into 2 groups of 111, including 19 and 17 yearlings. One group received during March and early April 1 mg. Co as 0·2 per cent. aqueous solution of Co nitrate per ewe daily. There was no effect of the Co on oestrus or percentage of ewes in lamb or on the birthweight of the lambs, but the number of twins in the Co group was greater, with low statistical significance.

In another flock of mutton Merinos the ewes were divided into 4 groups ; 61 ewes received 10 g. basic slag daily, 58 had 10 g. copper slag, 60 had 5 g. of each and 64 had no supplement. The percentage composition of the copper slag included Cu 0·47, Ni 0·014, Va 0·013, W 0·001, Fe oxide 5·76, SO_3 1·62, Zn 0·78, Ti 0·015, Cr 0·001, silicic acid 48·2, CaO 13·51, sulphite S 0·05, Mn 0·35, Co 0·002, Mo 0·001, Al_2O_3 22, MgO 5·92, P_2O_5 0·38 and alkalis. The basic slag included, per cent., CaO 50·8, Mn_2O_3 4·13, MgO 4·82, P_2O_5 18·35, Al_2O_3 1·03, S 0·2, Fe oxide 6·75 and silicic acid 12·86. The supplements were given during March and April.

The percentage of ewes which had lambs was not affected by the supplements. The total number of lambs was greatest in the group given no supplement, but was significantly less only in the group given copper slag alone. The number of twin births in this group was 15 per cent., compared with about 40 per cent. in the other groups. There was no effect on birthweight of lambs.

LOCKART, L. W. **The reaction of primary and secondary wool fibres to changes in nutrition.** *Austral. J. Agric. Res.*, 1956, **7**, 147–151. [Agric. Exp. Stat., Trangie, N.S.W.]

A skin section was taken from each of 32 rams at a period of plentiful feed and another at a period of poor feed and major and minor diameters of primary and secondary fibres were measured. In a second trial 3 adult ewes on a high nutritional plane were transferred to a low nutritional plane and similar measurements were taken at intervals of 2 weeks. The response of primary and secondary wool fibres to changes in nutrition was found to be in proportion to their cross-sectional area. Primary fibres did not appear to compete more effectively with secondary fibres at a low level of wool production than at a high one.—J. C. Gill.

5244

RYDER, M. L. **Observations on the fleeces of experimental sheep receiving daily doses of sodium fluoride.** *J. Agric. Sci.*, 1956, **47**, 187–190. [Wool Indust. Res. Assoc., Leeds.]

The wool was shorter, finer, less crimped, less lustrous and less greasy in 4 sheep given sodium fluoride than in 2 control sheep. The possible stages in the development of capsules associated with follicles, probably caused by the fluoride, are described. Data on the normal changes in the percentage of fibre shedding through the year are presented. Sodium fluoride did not appear to affect it.—J. C. Gill.

5245

SLEN, S. B. and WHITING, F. **Wool growth in mature range ewes as affected by stage and type of pregnancy and type of rearing.** *Canad. J. Agric. Sci.*, 1956, **36**, 8–13. [Div. Animal Husb., Exp. Farms Serv., Canada Dept. Agric., Lethbridge, Alta.]

In trials with 87 Corriedale ewes on a 10 to 13 per cent. protein diet and 317 on a 7 per cent. protein diet until 6 weeks from lambing and 10 per cent. thereafter, bi-monthly sampling showed that wool production, fibre length and density of fibre per unit area were significantly higher from those with single lambs than from those with twins during both pregnancy and lactation. Wool growth was significantly reduced by early and advanced pregnancy and by lactation. Reduction of fibre density occurred earlier in ewes on the lower protein ration. Fibre thickness was greater in ewes with single lambs than in ewes with twins during late pregnancy on the lower protein ration. Over the 8 months of the trial ewes with single lambs produced 19 per cent. more wool than those with twins on the low plane of nutrition, and 11 per cent. more on the high plane.—J. C. Gill.

5246

RYDER, M. L. **Observations of nutritional and seasonal changes in the fleeces of some Masham sheep.** *J. Agric. Sci.*, 1956, **47**, 129–144. [Wool Indust. Res. Assoc., Leeds.]

In a summer trial 2 sheep fed so as to lose a quarter of their weight did not shed their wool fibres, but did so during the following winter when fed on a good diet, owing probably to a seasonal stimulus. The numbers of blood vessels in the skin and the amount of glycogen in the outer root sheaths of the follicles were not affected by the poor feeding. Data on wool weight, fibre length and fibre diameter for the 2 experimental and 2 control animals are presented.—J. C. Gill.

LOCKART, L. W. **Variation in wool production per unit area of skin.** *Austral. J. Agric. Res.*, 1956, **7**, 158–161. [Agric. Exp. Stat., Trangie, N.S.W.]

A study of published data suggests that there is a considerable variation in production of wool per unit area of skin even under optimum conditions.—J. C. Gill.

5251
COOP, I. E. **The significance of face cover in Corriedale and Romney-Corriedale cross sheep.** *N.Z. J. Sci. Technol.* [*A*], 1956, **37**, 542–554. [Lincoln Coll.]

Records of 3000 ewes and 590 hoggets were studied. The sheep were classified into open-, intermediate- or cover-faced. The open-faced ewes were heavier, had a lower incidence of barrenness and weaned more and heavier lambs than the cover-faced, but their fleeces were somewhat lighter and of poorer quality. More cover-faced ewes could be carried per acre. The open-faced hoggets were heavier than the cover-faced, but the fleece differences were slight. Selection for open face is advocated.—T. D. Bell.

PIGS

5252
GILL, J. C. and THOMSON, W. **Effect of environmental temperature on suckling pigs and a study of the milk yield of the sow.** *J. Agric. Sci.*, 1956, **47**, 324–331. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

During 3 winters 8 sows and their litters were studied. Half of each litter were housed in a pen containing a small unheated cage, the other half in a pen containing a cage similar in size but lagged and heated. Both types of cage were bedded with straw for all litters except one, for which wooden floors were provided. The young pigs slept in the cages, used the pens as runs, and were returned to the sows for suckling at intervals of 1½ hr. for the first 40 days, and thereafter at intervals of 2 hr. until weaning at 56 days of age. The air temperatures in the unheated cages varied about means of about 44° F., those in the heated cages were about 17° F. higher.

The difference in environmental conditions before weaning did not significantly affect the amounts of milk sucked from the sow or the liveweights of the pigs at weaning. In comparison with pigs kept in the heated cages, pigs kept in the colder cages ate more creep feed, and their coats were hairy and dull. They also converted both milk and creep feed less efficiently.

One litter, half previously in a warm environment and half in a cold, was kept in cold conditions after weaning and 7 of the 8 pigs died of a liver disease. A second litter was kept to 12 weeks of age in the same cold environment as it had up to weaning and all animals survived. Five other litters were weaned and the pigs were kept in a uniform environment from then until they reached bacon weight. Of the group kept in the warmer environment until weaning 3 died of the liver disease and 2 of pericarditis. Of the group kept in the colder environment until weaning 5 died of pneumonia and 2 others died without the cause being ascertained. The pre-weaning treatments had no effect on feed conversion efficiency or rate of liveweight gain after weaning, nor did they affect carcase quality.

The lactation curves of the sows reached their peaks at about 3 weeks after farrowing and maintained that level with some fluctuations until they fell off rapidly before weaning. The total milk yield per sow from the 3rd to the 56th day of

lactation ranged from 445 to 764 lb., average 605 lb. It was estimated that 412 Cal. net energy are required by a sow to produce 1 lb. milk.

I. A. M. Lucas.

RUNTZIS, A. Ya. Vliyanie ponizhennoi temperatury na vyrashchivanie svinei. [**Influence of low temperature on the rearing of pigs.**] *Zhivotnovodstvo*, 1956, No. 2, 76–77. [Ist. Zootekh., Akad. Nauk Latviisk. SSR.]

Low temperatures, about — 0·7° [C?], combined with good feeding and management had a good effect on young pigs. They developed more rapidly, had a better appetite and were more resistant to disease than control animals reared at higher temperatures.—H. Scherbatoff.

5254

HANSON, L. E. and FERRIN, E. F. **Effect of antibacterial agents on the growth of suckling pigs.** *J. Animal Sci.*, 1956, **15,** 376–391. [Univ. Minnesota, St. Paul.]

Seven trials are reported in which sucking pigs were given supplements of oxytetracycline, bacitracin, penicillin, chlortetracycline or arsanilic acid in their creep feed. Oxytetracycline, used in one trial only, at 5 mg. per lb. feed, improved gains and prevented scours. Bacitracin partly prevented scours but did not increase rate of liveweight increase. In this trial, as in all the others, chlortetracycline improved rate of gain and prevented scours when they occurred in untreated groups. Penicillin given at levels of 5, 10 and 20 mg. per lb. feed gave weight gains better than those of controls, but was ineffective at a level of 2·5 mg. per lb. Arsanilic acid also improved growth rates.

In one trial subcutaneous implantation of bacitracin at 3 days of age did not affect growth of the piglets receiving no antibiotic in the creep feed.

GILL, J. C. and THOMSON, W. **Observations on the behaviour of suckling pigs.** *Brit. J. Animal Behaviour*, 1956, **4,** 46–51. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Eight litters were studied, in which the piglets sucked almost as soon as they were born. The suckling period was divided into 3 phases, preliminary massage lasting on the average 60·5 sec., milk let-down, 14·2 sec., and final massage 149·3 sec. There was apparently a correlation between the total milk yield of the sow and the total time spent in massage during each nursing, and when a sow habitually lay on one side or the other, the milk obtained from the teats on the under side, which were not so well massaged by the piglets, was less than that obtained from the upper side. When the sow stood massage was less vigorous and milk yield was less. More milk was obtained from the anterior than from the posterior teats. Rate of growth of the piglets to 19 days of age was highly correlated with the amount of milk they consumed. The lactation curve of the sows rose sharply for the first 3 weeks, then the level was maintained until the last week, when it declined rapidly.—T. D. Bell.

TCHIDERER, K. Betriebswirtschaftliche Untersuchungen über die Fütterungstechnik bei Schweinen. [**Practical studies of feeding technique with pigs.**] *Arch. Tierernährung*, 1956, **6,** 44–49. [Schweine-Versuchsanst., Landwirtschaftskammer für Niederösterreich, Vienna.]

The varying results of attempts in different countries to avoid feeding pigs on Sundays are summarised. Since a preliminary trial early in 1953 with 2 groups each of 10 pigs showed no ill effect of a Sunday fast on average daily weight gain or feed efficiency, a comparison was made between 100 German Edelschwein fattened in the usual way in the summer of 1952 and 100 similar pigs fattened without Sunday feeding in the summer of 1953. The pigs were penned individually and fed to appetite at 6.30 a.m. and 3.30 p.m. Monday to Saturday, without a double portion on Saturday or Monday; water was supplied on Saturday evening and the pigs were left alone on Sunday; complete quiet on the fast day is regarded as important. The percentage composition of the ration was maize 44, barley 44, ground lucerne meal 7, yeast 3, mineral mixture 2 (chalk 62·5, steamed bonemeal 20, iodised salt 15, ferrous sulphate 1·6, manganese sulphate 0·6, copper sulphate 0·3 per cent.), given as a thick slop with sour skimmed milk, 1 to 3 litres per pig daily; the pigs also had 5000 I.U. vitamin D_3 each weekly.

The pigs not fed on Sundays took longer to reach slaughter weight, and slaughter losses were slightly greater. Feed efficiency was unaffected. They had longer bodies and thinner back and belly fat. The fat : flesh ratio was less and the proportion of desirable cuts greater. These differences were significant.—W. M. Deans.

5257

LASSITER, J. W., TERRILL, S. W., BECKER, D. E. and NORTON, H. W. **Protein levels for pigs as studied by nitrogen balance.** *J. Animal Sci.*, 1956, **15,** 392–399. [Illinois Agric. Exp. Stat., Urbana.]

N balance trials with 4 sets of 4 pigs of about 50 lb. liveweight and 4 sets of 4 pigs of about 150 lb. liveweight are reported. The pigs were given a ration of maize and a protein supplement, fortified

with minerals, vitamins and antibiotic, in 2 equal feeds daily : 1 lb. feed was given to the small and 4·5 lb. to the large pigs. After a 10-day preliminary period urine and faeces were collected during consecutive periods, one of 3 days and 2 of 2 days. Protein levels for the 4 sets of pigs of each size were 10, 14, 18 and 22 per cent.

In the smaller pigs N retention increased to the 18 per cent. protein level. With the larger pigs there was some evidence that protein level affected N retention, but the differences due to protein level were not significant. The results are discussed in relation to those of growth trials with the same feed for pigs from weaning to 100 lb. liveweight, and other conditions affecting protein utilisation are mentioned.

With a sufficiently long preliminary period of 10 days there was no added advantage in extending the collection period from 3 to 5 or 7 days.

T. D. Bell.

5258

HVIDSTEN, H. and HUSBY, M. Forsøk med ulike proteinformidler til slaktegriser. [**Experiments with different protein supplements for bacon pigs.**] *Meld. Norges Landbrukshøgsk.*, 1955–56, **35**, 23–70. [Norges Landbrukshøgsk.] English summary.

There were 24 experiments with in all 240 pigs and, as supplements to a normal cereal diet, ordinary herring meal, whalemeal, soya bean meal, a mixture of oilcakes, fish solubles, whole fish meal, herring meal made from fresh herring and herring meal from herring preserved with nitrite. The digestibility of some of the feeds was estimated with wethers. Eighteen of the experiments date back to 1932–1934 but have not been published before. They compared herring meal of good quality with oilseed meals and cakes. The remaining 6 experiments were made in 1949–1951 to compare the new meals with one another and with soya bean meal. The results are presented in graphs and tables ; some of the tables have headings in English.

In the 18 older experiments together, the mean daily rate of gain with herring meal was 541 g., with oilseed meals and cakes 509 g. In the more recent tests there was no clear differences between the several animal proteins ; on the average, growth with animal protein was 18 per cent. faster than with soya bean. Whalemeal gave the bacon a characteristic, not unpleasant, taste. Back fat was thicker with soya bean meal.

On the basis of tests with wethers, whole herring meal with 90·8 per cent. dry matter had per kg. 634 g. digestible crude protein, 1·39 Scandinavian feed unit or 1·07 feed unit for fattening ; whole meal of whale flesh had, in the same order, 634, 1·32 and 0·98.—I. Leitch.

5259

BARBER, R. S., BRAUDE, R. and MITCHELL, K. G. **Formalin-treated skim milk for pigs.** *Agriculture, J. Minist. Agric. Engl.*, 1956, **63**, 111–114. [Nat. Inst. Res. Dairying, Reading.]

Formalin was added to skimmed milk in 3 tanks in a concentration of 0·1, 0·2 or 0·5 per cent. Some milk was withdrawn daily from each tank, leaving 4 gal. in each at the end of 1 week. More skimmed milk and appropriate amounts of formalin were then added and the process was repeated. With 0·1 per cent. formalin the milk clotted after 4 weeks, at the other 2 concentrations it clotted after $6\frac{1}{2}$ weeks.

In other tests the milk remaining in the tanks was run off each week and the tanks were rinsed with cold water before being re-filled with milk and formalin. The numbers of weeks before the milk clotted varied widely and there was no consistent difference between samples containing 0·1 or 0·2 per cent. formalin.

In a feeding experiment weanling pigs each consumed 1 gal. daily of fresh skimmed milk, but others would take only $\frac{1}{2}$ gal. daily of skimmed milk containing 0·5 per cent. formalin until they each weighed about 90 lb. liveweight. Apart from a dislike of the formalin-treated milk the pigs remained thrifty. During the subsequent 8 weeks pigs in both lots consumed their full allowance of milk and grew equally rapidly, indicating that skimmed milk preserved with as much as 0·5 per cent. formalin could be given to pigs in the later stages of fattening. The milk did not cause off-flavours in the bacon.

On 2 commercial farms the addition of formalin at the rate of 0·1 to 0·2 per cent. of the skimmed milk prevented clotting for 8 or 9 days. There was some vomiting in the younger pigs given formalin-treated milk twice daily, but when the milk was given 4 times daily on one farm the vomiting ceased.—I. A. M. Lucas.

REES, D. H. and WESTMACOTT, M. H. **The feeding of fodder beet to pigs.** *J. Agric. Sci.*, 1956, **47**, 232–237. [Rothamsted Exp. Stat., Harpenden, Herts.]

The results of 9 sets of experiments, 3 in Denmark, 5 in England and one in Northern Ireland, on the use of fodder beet of high dry matter content, 18·5 to 22·5 per cent., for fattening pigs are summarised. In all experiments except 2 of the Danish series, meal was restricted and fodder beet given to appetite.

When fodder beet was given the daily intake of energy by the pigs was reduced, and growth rates were lower. There was a suggestion in some of the experiments that when the lower protein intake due to the replacement of concentrate by fodder beet

was compensated by using meal with a higher percentage of protein, growth rates were improved. When fodder beet with restricted meal or meal only was given there was no difference in the amount of starch equivalent required per lb. liveweight increase. Observed replacement values of fodder beet for meal, when reduced growth rates were not considered, agreed well with the values calculated from the dry matter content of the beet and the starch equivalent value of the meal taken from Woodman's tables. Observed values were from 4·8 to 6·3 and calculated from 4·8 to 5·2 lb. beet per lb. meal. In the Danish experiments carcase quality was slightly less good when beet was given, but in the other experiments reported the opposite was found.—T. D. Bell.

5261

RICHTER, K., CRANZ, K. L. and OSLAGE, H. J. Vergleichende Untersuchungen über den Einfluss einer unterschiedlichen Fütterung von Schweinen mit Getreide, Kartoffeln, und Zuckerrüben auf Mastentwicklung und Schlachtqualität. [**Comparative studies of the effect of some alternative rations for pigs, with grain, potatoes and sugar beet, on fattening and slaughter quality.**] *Züchtungskunde*, 1956, **28**, 93–104. [Inst. Tierernährung, Brunswick, Völkenrode.] English summary.

There were 6 groups of 8 pigs and 3 groups of 9, all initially comparable. There were 3 types of diet, one based on barley, one on potatoes and one on 2 parts sugar beet and 1 part potatoes; both the bulky diets included 1 kg. concentrates daily. With each diet pigs were killed at 3 weights, about 135 to 150 kg., 120 to 135 kg. and 110 to 120 kg.

The differences with diet in rate and efficiency of gain, feed conversion and carcase quality were not significant. The carcase measurements are tabulated. In the heaviest pigs the meat : fat ratio was significantly better on the sugar beet and potato diet and in the smallest pigs it was better on the barley diet, but the quality of the ham was similar and so was that of the back fat. There was a longer large intestine in pigs fed on the bulky diets.—D. Duncan.

5262

DANILENKO, I. A. and BELOGUB, D. K. Silosovanie i ispol'zovanie kukuruzy dlya kormleniya svinei. [**Ensilage and use of maize for pig feeding.**] *Zhivotnovodstvo*, 1955, No. 8, 7–10. [Ukrain. Nauch.-Issled. Inst. Zhivot.]

Results are given of experiments with maize silage which show that the quality of meat and lard is best from pigs fed on maize cobs ensiled at the milky-wax or the milky stage.

H. Scherbatoff.

5263

BEREZHNAYA, P. P. Opyt otkorma svinei kukuruzoi i sochnymi kormami. [**Feeding pigs with maize and succulent fodders.**] *Zhivotnovodstvo*, 1955, No. 8, 33–39.

5264

GORB, T. V. and KLITZENKO, S. T. Opyt prigotovleniya i ispol'zovaniya kukuruznogo silosa dlya svinei. [**Preparation and use of maize silage for pigs.**] *Zhivotnovodstvo*, 1955, No. 9, 102–104.

Silage made from maize cobs at either the milky-waxy or the waxy stage, mixed with succulent fodder, legume hay or grass was readily eaten by pigs and supplied them with almost all the necessary nutrients. The silage was mixed with concentrates and root vegetables before being given to the pigs.—H. Scherbatoff.

5265

KOVALENKO, N. A. Ispol'zovanie kukuruzy pri otkorme svinei. [**Maize for pig feeding.**] *Zhivotnovodstvo*, 1955, No. 10, 17–20.

Grain can be almost entirely replaced in the rations of fattening pigs by silage made of maize cobs. When unripe maize cobs are given to pigs it is necessary to add chalk and salt. To encourage pigs to eat maize silage they should be started on small amounts, 0·5 to 0·8 kg. daily, and reach the full amount [not stated] in 5 to 6 days.

H. Scherbatoff.

5266

WALLACE, H. D., CUNHA, T. J. and COMBS, G. E. **Low-gossypol cottonseed meal as a source of protein for swine.** *Univ. Florida Agric. Exp. Stat. Bull.* No. 566, June 1955, pp. 26.

Trials made over 4 years with growing and fattening pigs and pregnant and lactating sows are reported. In the first trial 3 commercial cottonseed meals containing over 0·063 per cent. free gossypol as the source of protein were unsatisfactory for growth and fattening. A fourth meal with only 0·024 per cent. was better, though gains were not optimum, and aminoacid, vitamin A or vitamin B complex supplements were ineffective. The value of an animal-protein factor supplement was demonstrated.

In the other trials with growing and fattening pigs supplements of 0·4 per cent. lysine with or without 0·075 per cent. methionine did not improve performance on a ration in which the source of protein was low-gossypol cottonseed meal, when compared with a ration in which soya bean oilmeal supplied the protein. A supplement of 0·8 per cent. lysine was effective. Other supplements tried were distiller's solubles concentrate, crude cottonseed oil, waste beef fat, a surface-active

compound, condensed fish solubles, Cu and Zn, all of which were without effect. A high level of Aurofac was of some advantage, and the results with Fe sulphate were good in 4 out of 6 trials. In the pigs not performing satisfactorily there was no clear evidence of gossypol poisoning, but since Fe was of some value in counteracting the effect of the cottonseed meal it was thought that the unthriftiness may have been due to the gossypol. In all groups getting the cottonseed meal there was great variation between individuals, which was not found in the groups getting soya bean meal instead.

For pregnant and lactating gilts and sows cottonseed meal and soya bean meal as sources of protein were of equal value when farrowing, nursing and development of litters were considered.

5267

HANSON, L. E., PRITCHARD, W. R., REHFELD, C. E., PERMAN, V., SAUTTER, J. H. and SCHULTZE, M. O. **Studies on trichloroethylene-extracted feeds. 9. Experiments with swine fed trichloroethylene-extracted soybean oil meal.** *J. Animal Sci.*, 1956, **15,** 368–375. [Dept. Animal Husb., Sch. Vet. Med., Univ. Minnesota, St. Paul.]

For parts 1 and 2 see Abst. 1162, Vol. 23.

Soya bean oilmeals extracted with hexane or trichloroethylene, the latter known to be toxic to cattle, were compared at levels of 10 to 20 per cent. of the ration in terms of the growth of weanling gilts, their subsequent reproduction, and the growth of their offspring. No significant difference was found on any of these counts attributable to the method of extraction of the soya beans.

BAINTNER, K. and JELENITS, K. Különféle élesztők értéke a sertések hizlalásában. [**Value of different yeasts for fattening pigs.**] *Rep. Fac. Animal Husb., Hung. Univ. Agric. Sci.*, 1955, **1,** No. 4, 27–64. [Inst. Animal Nutrit., Univ. Agric. Sci., Budapest.] Russian, German and English summaries.

In experiments with pigs the values of brewer's yeast dried at 110° C. and of samples of baker's yeast dried at 60° to 70° C. were compared. Both kinds of yeast improved the performance of pigs on all-vegetable rations, and in some experiments the results with baker's yeast were even better when Aurofac and a preparation containing vitamin B_{12} (Vitagen) were given also. In one experiment this combination gave better results than a supplement of animal protein. Up to 7 per cent. yeast was given without ill effect. (From English summary.)—D. Duncan.

5269

GLAPŚ, J. and RUSZCZYC, Z. Badania nad zastosowaniem drożdży pastewnych i kukurydzy w tuczu trzody chlewnej. [**Studies on the use of fodder yeast and maize in the fattening of pigs.**] *Rocz. Nauk rol.* [*B*], 1955, **70,** 139–152. [Inst. Zootech., Cracow.] Russian and English summaries.

Provided the feed mixture for pigs contained maize, fodder yeast could be used to replace all the fishmeal. When potatoes were used for fattening pigs, and no maize was given, greater gains were produced by fishmeal than when maize was included in the ration, but on potatoes alone fodder yeast did not give as good gains as fishmeal, and the fattening period was prolonged. Concentrates and maize only for fattening were not as good as a feeding system including potatoes. Apparently slight changes in the diet affected differently the development of certain organs and tissues. Rate of gain was not influenced by sex. (From English summary.)—T. D. Bell.

5270

RUSZCZYC, Z. and GLAPŚ, J. Zastosowanie gęstwy drożdżowej (suszonych drożdży piwnych) w tuczu trzody chlewnej. [**The use of yeast slop (fresh brewery yeast) for fattening pigs.**] *Rocz. Nauk rol.* [*B*], 1955, **70,** 153–167. [Inst. Zootech., Cracow.] Russian and English summaries.

From a feeding trial with 32 male and 32 female pigs fattened from 40 to 110 kg. liveweight the following conclusions were drawn. Fresh brewery yeast, 600 to 900 g. daily, could be given, replacing some of the concentrate mixture and saving 47 kg. concentrate per pig. When the concentrate had only vegetable protein, utilisation of the feed was improved by the brewery yeast and the fattening period was reduced, but this was not so when animal protein was included in the concentrate. Pigs getting animal protein gained faster and more efficiently than those getting vegetable protein only. Fresh brewery yeast given up to the time of slaughter caused watery flesh. It was thought this could be avoided by stopping the yeast a few weeks before slaughter. If this were done brewery yeast would be a useful feed for fattening pigs, but since it cannot be stored its use would be limited to the immediate neighbourhood of the breweries. (From English summary.)

5271

RUSZCZYC, Z. and GLAPŚ, J. Zastosowanie drożdży posulfitowych w tuczu trzody chlewnej. [**The use of post-sulphite yeast in the fattening of pigs.**] *Rocz. Nauk rol.* [*B*], 1955, **70,** 169–180. [Inst. Zootech., Cracow.] Russian and English summaries.

A trial is reported in which there were 3 groups of 6 Large White pigs, 3 male and 3 female in each group. Group 1 was given a concentrate mixture containing fishmeal, group 2 post-sulphite yeast and group 3 fodder yeast instead of fishmeal. In weight gain there was no significant difference between groups 2 and 3. When given with potatoes, barley and rye bran, fishmeal was better than either of the yeasts for both rate of gain and efficiency of feed utilisation. Fishmeal also gave carcases of better grade with firmer fat. (From English summary.)—T. D. Bell.

5272

BIELIŃSKI, K. Badania nad określeniem wartości pokarmowej pektynowanych plew lnianych w tuczu trzody chlewnej. [**Studies on the nutritive value of pectinised flax chaff for fattening pigs.**] *Rocz. Nauk rol.* [*B*], 1955, **70,** 121–137. [Inst. Zootech., Z.D. Kołuda Wielka.] Russian and English summaries.

A pectin extract obtained as a by-product in the process for extracting fibre from flax was mixed with flax chaff in the proportion of 1 : 3 and pressed into cakes. The pectinised chaff had the following composition : dry matter 90·3, digestible protein 3·2, total digestible nutrients 42·8 per cent.

It was used to replace 15 per cent., increased to 25 per cent. near the end of the feeding period, of the potato flakes and barley for fattening pigs from 41 to 90 kg. liveweight. Average daily liveweight increase was 593 g. Similar animals on the normal ration without flax chaff gained 611 g. daily. In efficiency of feed utilisation the animals getting flax chaff were inferior to the others, requiring 5·50 feed units (F.U.) and 546 g. digestible protein per kg. liveweight increase, compared with 5·08 F.U. and 458 g.

Carcase grading of the pigs getting chaff was similar to that of the other pigs, except that there was more fat in the loin ; but livers were heavier, 2149 g. compared with 1716 g., and the tissue of the digestive tract was darker. During the experiment the pectinised flax chaff caused some scouring. It was concluded that the proportion of barley and potato flakes replaced by the chaff was too high. (From English summary.)

PLUMLEE, M. P., THRASHER, D. M., BEESON, W. M., ANDREWS, F. N. and PARKER, H. E. **The effects of a manganese deficiency upon the growth, development, and reproduction of swine.** *J. Animal Sci.*, 1956, **15,** 352–367. [Dept. Animal Husb., Purdue Univ. Agric. Exp. Stat., Lafayette, Ind.]

Four experiments are reported. In the first, 9 weanling Duroc boars, liveweight 35 lb., were hand-fed on a purified ration containing 1·5, 20·5, or 34·0 p.p.m. Mn. During the trial, lasting 14 weeks, there was no significant difference in liveweight increase between the groups. The Mn content of the livers, on a dry weight basis, was 2·2, 10·4 and 12·3 p.p.m. for the low, medium and high groups, respectively.

The 2 groups each of 6 pigs in the second trial were similarly managed, but the rations contained 1·4 or 40·0 p.p.m. Mn. The pigs were fed from 43 to 246 lb. liveweight. Rate of weight gain in both groups was similar. For the low and high Mn groups, respectively, the Mn contents of liver, heart, thyroid and testes were, in p.p.m. : 4·6, 12·1 ; 0·65, 1·53 ; 0·37, 0·91 ; 0·99, 2·69. The Mn content of blood was 5·95 and 6·96 μg. per 100 ml. On 1·4 p.p.m. Mn there was a tendency towards " sickle-hocks".

The levels of Mn tested in the third trial were 1·0 and 38·0 p.p.m. in rations containing maize and 3·4 and 40·0 p.p.m. in rations where the maize was replaced by cerelose. They were given to 4 groups of 4 Duroc gilts up to about 250 lb. liveweight. Between groups no difference in weight gain, efficiency, number of piglets farrowed, or viability or birthweights of the litters could be attributed to the levels of Mn given. Total Mn in soft tissues of both gilts and offspring was about 50 per cent. less in pigs on lower levels of Mn. There was no difference between groups in organ weights, blood phosphatase, or phosphorus or manganese content of the hock bones. Boars from the gilts getting low Mn and those getting high Mn, all reared on rations with 3·3 p.p.m. Mn, performed equally well and showed normal spermatogenesis.

Finally 20 female suckling pigs, 9·4 lb. liveweight, were given semi-purified rations containing

0·5 or 40·0 p.p.m. Mn throughout growth, gestation and lactation. After farrowing, colostrum was analysed, and the piglets were suckled by the sows, with access to their rations, and weaned at 6 weeks. Growth rate and feed efficiency were satisfactory at both levels. Signs of Mn deficiency, manifested by discomfort and weakness of the legs at 60 lb. liveweight, shortened and thickened front legs, becoming bowed by 90 lb. liveweight, appeared in the low-Mn gilts, and they were shorter in the body and too fat. X-ray photographs of the legs showed that growth of the radius was prevented by closure of the distal epiphyseal plate. Liver, spleen, pituitary, thyroid and reproductive organs were histologically normal.

The depleted gilts, during the breeding season, showed irregular oestrus and sometimes would not accept the boar, although examination showed normal ovulation. Of those mated, 5 in all, only 2 farrowed.

The litters from the high-Mn gilts were presented normally and were vigorous and healthy. Those of the depleted gilts were weak, with poor balance, inco-ordination, and inability to suck. All of one litter of 7 died within a week, and the other, of 4 piglets, died even when transferred to a diet containing 40 p.p.m. Mn. The soft tissues of the low-Mn gilts had less Mn than those of the high Mn, and the colostrum contained 0·27 and 0·38 p.p.m., respectively, for gilts on low and high levels of Mn.—T. D. Bell.

DOYLE, L. P., TURMAN, E. J. and ANDREWS, F. N. **Some pathological effects of anterior pituitary growth hormone preparations on swine.** *Amer. J. Vet. Res.*, 1956, **17**, 174–178. [Dept. Vet. Sci., Purdue Univ., Lafayette, Ind.]

In 3 trials with castrated pigs of initial liveweight 100 to 115 lb., fattened to 220 lb., 11 pigs were given by intramuscular injection different amounts of anterior pituitary growth hormone preparations, and in each trial untreated pigs were kept as controls.

In the first trial there were 2 pigs treated, one with 10 mg. and the other with 5 mg. hormone per 15 kg. bodyweight daily. No ill effect resulted, rate of gain was excellent, efficiency was better than in untreated pigs and the edible carcase had more protein and less fat.

In the second trial 2 pigs got 4·5 mg. daily per 15 kg. bodyweight, of a different preparation of the hormone, 2 got 2·25 mg., and 3 were untreated. Growth was good in all pigs until the 30th day when 1 pig getting the higher dose went off feed; it died with convulsions 9 days later. The other pig on the same dose died similarly, between the 40th and 45th days. The pigs getting the smaller dose gained faster and more efficiently than controls, and their edible carcases had more protein and less fat.

One pig in the third trial received the same dose of the same preparation as the 2 which died in the previous experiment. Two pigs got a third preparation at 6 mg. per 15 kg. bodyweight daily, and 2 at 3 mg. The first and the last pigs were more efficient and had less fat and more protein in the edible carcase, but growth rate of the pig getting 4·5 mg. hormone was below that of controls. Feed was refused by the pigs getting 6 mg. hormone on the 7th and 11th days. One died on the 17th day. Injections were discontinued in the other, and it recovered in 10 days, but when they were started again death ensued within 3 weeks.

Macroscopic and histological findings at post-mortem examination of the pigs which died included damage to the heart, lungs, liver and kidney, and oedema. The findings in each pig are described in detail.—T. D. Bell.

RAIMONDI, R. Alcuni indirizzi tradizionali della suinicoltura italiana al controllo della sperimentazione. [**Some traditional methods of pig breeding in Italy examined experimentally.**] *Riv. Zootec.*, 1956, **29,** 80–89. [Ist. Zootec. Piemonte, Turin.]

The traditional method of pig breeding in north-eastern Italy since the end of last century has been to cross native sows with Large or Middle White boars, giving good pigs for fattening. The crosses were well suited to the conditions of fattening, usually in the woods and meadows, with little use of concentrates. Native sows also were maintained almost entirely in this manner. The market demand was for a fat pig, which the crosses provided. In the changing conditions of the present day a more intense agriculture is bringing the semi-wild regions into cultivation and more stall- or yard-fattening of pigs must be practised.

A trial with 4 groups of pigs was made. The groups, of 6 pigs each, represented Large White purebred, Large White × Cinta Senese, S. Lazzaro (a Large White locally inbred since 1875) × Romagnola, and Large White × Garlasco. All pigs were fed on the same concentrate mixture, skimmed milk and water, as a thick slop, twice daily. The same amounts on a liveweight basis were given to each pig. The pigs were weaned at about 74 days old, and the trial continued for 200 days, when liveweights were about 130 to 156 kg.

Up to 110 days, 85 to 95 kg. liveweight, there was little difference between the breeds in liveweight increase or economy of gain. In the last 90 days the Large Whites gained faster than the crosses, and rates of daily gain over the whole period were 0·670, 0·592, 0·589 and 0·546 kg. for the groups in the order first named. Since almost equal amounts of feed were eaten economy of gain was also in the same order, 3·72, 4·21, 4·22 and 4·56 feed units per lb. liveweight increase. Large Whites gave the leanest and Large White × Garlasco the fattest carcases.

It is suggested that since there is now little demand for fat carcases policy should be directed to breeding Large Whites, maintaining the native breeds only where semi-wild conditions demand it, and carefully selecting the native pigs retained.

LUCAS, I. A. M. and CALDER, A. F. C. **The response of different types of pigs to varying levels of feeding from weaning to bacon weight, with particular reference to carcass quality.** *J. Agric. Sci.*, 1956, **47,** 287–323. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

A review of the literature shows that restriction of feed intake by growing and fattening pigs does not in itself improve efficiency of feed conversion. When feed is severely restricted carcase quality is improved, but the time required to reach slaughter weight is too long for practical purposes, and small restrictions give only slight improvement which may be influenced by the genetic make-up of the pig more than by the plane of feeding.

In the experiments reported these findings were investigated. The breeds compared in each experiment were representative of lean and fatter types, and 3 planes of feeding were used. In the first experiment litters out of Large White sows by Wessex Saddleback and Swedish Landrace boars represented the fatter and lean types, respectively, and in the second the litters were by a Swedish Landrace boar out of a Large White sow for the lean type, and by a Large White boar out of an Essex Saddleback sow for the fatter. In each experiment group 1 had a high plane of nutrition from weaning to 100 lb. liveweight and from 100 lb. to 200 lb. Group 2 was fed on the high plane to 100 lb. and was restricted from 100 to 200 lb., and group 3 was on a low plane in both periods. In the second experiment the restriction imposed on group 2 was more severe than in the first, but group 3 was allowed more than in the first.

In both experiments time taken to reach bacon weight was much longer for group 3, and almost 2 weeks longer for group 2 than for group 1. There was no difference between breeds in the first experiment; in the second the lean type in groups 1 and 2 grew faster, but in group 3 the position was reversed.

Efficiency of feed conversion did not differ between breeds in experiment 1, and between groups, group 3 was inferior to groups 1 and 2. The lean type in the second experiment was more efficient in groups 1 and 2, but the fatter type in group 3. When the effect of breed was eliminated groups 1 and 2 were equal but group 3 was inferior.

The differences in carcase quality between types were slight, in favour of the leaner types. The improvement due to restricted feeding in group 2 was of the same magnitude. In group 3 a greater improvement was obtained, but the carcases tended to be soft, though it was not possible to record the iodine numbers to confirm this.

Only in experiment 2 was there a difference between sexes in growth rate, and then only from 100 to 200 lb. liveweight did females grow faster than males in groups 1 and 2, but males faster than females in group 3. Also in this experiment females were more efficient than males in groups 1 and 2 and males than females in group 3. Length of carcase was greater in females in all groups and experiments, and they also had less shoulder fat and a larger area of eye muscle. On the other hand, restricted feeding from 100 to 200 lb. liveweight gave greater improvement in females in

these respects, although it was the males which had greater need of improvement.

It is concluded that choice of type of pig is more important than close regulation of plane of nutrition in improving carcases produced for bacon, and other conditions, including housing, are of great importance (Absts. 5873, Vol. 25 and 2538, Vol. 26).—T. D. Bell.

HORN, A. and FEKETE, L. A sertéshús minőségének javítása vágás előtti takarmányozással. **[Improvement of the quality of pork by special feeding before slaughter.]** *Rep. Fac. Animal Husb., Hung. Univ. Agric. Sci.*, 1955, **1,** No. 8, 3–11. [Inst. Animal Breeding, Univ. Agric. Sci., Budapest.] Russian, German and English summaries.

Most of the lactic acid of carcases is formed from glycogen, after death, and a study was made of the possibility of increasing carcase glycogen and thus the lactic acid content. Of 2 groups each of 5 pork pigs 11 months old and weighing about 145 kg., one group was fasted as usual for a day at the slaughterhouse and the animals of the other group were given a feed containing 750 g. sugar.

The *p*H of the meat of pigs given sugar was consistently lower than that of the starved pigs, both when the meat was kept at 36° C. for 36 hr. and when it was kept at from 9° to 13° C. for more than 3 weeks. The colour of the meat also was improved in the pigs given sugar. (From English summary.)—D. Duncan.

PERRY, J. S. **Observations on reproduction in a pedigree herd of Large White Pigs.** *J. Agric. Sci.*, 1956, **47,** 332–343. [Agric. Res. Counc. Inst. Animal Physiol., Babraham, Cambridge.]

The records from the Agricultural Research Council Field Station, Compton, refer to 247 pregnancies in 85 pigs. Mean duration of pregnancy was 114·17 $\pm$ 0·144 days and there was no effect of litter number (age of sow); nor was duration of pregnancy related to number of pigs born alive, except for pregnancies of more than 116 days, in which there was a significant deficit of live pigs. In 157 records of number stillborn there was no relation to length of gestation.

Sows were usually not bred until 8 months old or more. Average total litter size at birth rose to the fifth, sixth and seventh litters and fell thereafter. When only live-born pigs were considered, the peak came at litter 5; stillbirths were most frequent in litters 6 and 7. The proportion of pigs born dead decreased from 3·1 per cent. in litters of 3 to 8 (average 7), to zero in litters of 11, and rose to 10·2 in litters of 16 to 24 (average 18).

There was no difference in sex ratio between small and large litters, or early and late litters. Total weight of litter rose with size of litter, average weight declined from 3·12 lb. for 7 pigs to 2·55 lb. for 9·5 pigs and 2·29 for 18 pigs.

Records for number born alive in 163 litters [in text 110] with a total of 2026 pigs gave an average of 12·4 per litter; records of 322 litters weaned [in text 252] gave an average of only 8·1, suggesting a mortality of nearly 35 per cent., but wrongly, because pigs killed as "superfluous" were not separately recorded.

Sterility, or slow breeding, was less important as a reason for disposal of sows than mastitis and "failure to rear a litter of economical size"; of 136 sows 10 are shown as sterile and 13 as discarded for mastitis and poor performance.

I. Leitch.

WEIPERS, M. and INGLIS, J. S. S. **Studies on the relationship of the nutrition and management of the sow to the health of litters.** *Vet. Rec.*, 1956, **68,** 315–316. [Vet. Sch., Univ. Glasgow.]

Sows and gilts were given a balanced ration of meal, 6 lb. per head daily, increased to 8 lb. a fortnight before farrowing. After farrowing the meal allowance was dictated by the size of the litter. There were 3 groups of 6 each, served by the same boar. Group 1 were kept on pasture during pregnancy and moved into arks with a grass run from farrowing until weaning. Group 2 were kept indoors on concrete for the whole time, and group 3 were on pasture until farrowing, then moved to concrete-floored farrowing pens where they remained until weaning. For groups 1, 2 and 3, respectively, average numbers of pigs farrowed per litter were 12·0, 8·4 and 11·7, and average numbers weaned were 9·5, 4·4 and 9·2. Death rates of piglets were 20·1, 47·6 and 21·4 per cent. Pigs in groups 1 and 3 were healthier and more uniform at birth. The possible reasons for the beneficial effect of pasture during pregnancy are discussed, and it is hoped to investigate this further.—T. D. Bell.

5288

HORST, P. Untersuchungen über Länge und Volumen des Schweinedarmes und die Möglichkeit ihrer Beeinflussung durch die Fütterung. **[Length and volume of the pig intestine and the possibility of altering it by diet.]** *Ztschr. Tierernährung Futtermittelk.*, 1956, **11,** 88–108. [Inst. Tierzücht., Fak. Landbau, Tech. Univ., Berlin-Charlottenburg.] English summary.

Pigs weighing 30 kg. were divided into 2 groups ; 18 pigs received a ration high in ballast and 16 controls a ration low in ballast. The first group had initially 56 per cent. wheat bran. 28 per cent. weatings and 16 per cent. protein concentrate ; the proportions were changed at 50 kg. liveweight to 62, 30 and 8 and at 70 kg. to 64, 32 and 4. The second group had initially 84 parts barley meal and 16 parts protein concentrate ; at 50 kg. 9 of them had 92 parts barley meal and 8 parts protein feed, and 96 and 4 parts from 70 kg., but the other 7 had 78·5 parts barley meal, 6·8 parts protein feed and 14·7 parts " Steffenschnitzel " (sugar beet slices), changing at 70 kg. to 79·2, 3·3 and 17·5 parts. All the pigs were killed at 110 kg. without fasting. The length of the digestive tract, its weight both full and empty, and its volume when filled with air at 33·2 mm. water pressure were estimated.

In the pigs with higher ballast intake the stomach, small intestine and total digestive tract were significantly heavier than those of controls, but the difference in the colon and caecum was not significant. The length and volume of the digestive tract varied widely in both groups, but there was no significant difference with diet. The contents of stomach and small intestine weighed about the same in both groups, but the large intestine and the whole tract contained significantly more in the high-ballast group.

In 8 pigs fed individually for the last 4 weeks of the experiment there was no relation between total volume of the tract and total feed intake. It was concluded that the capacity of the digestive tract does not influence feed intake.—D. Duncan.

KLIESCH, J. and BANKWITZ-SILBER, E. Röntgenologische Untersuchungen über den Zusammenhang zwischen Körperlänge, Wirbelzahl und Wirbelgrösse an Ferkeln im Alter von 7–10 Tagen. [**X-ray studies of the relations between body length and number and size of vertebrae in pigs at the age of 7 to 10 days.**] *Züchtungskunde*, 1956, **28,** 208–211. [Inst. Tierzucht., Tech. Univ., Berlin.]

The pigs examined were all from the Institute's herd and X-ray photographs were made when they were 7 to 10 days old. The number of presacral vertebrae was in 102 pigs 27, in 158 pigs 28 and in 7 pigs 29. In these 3 groups the number of animals with 14, 15 and 16 pairs of ribs, respectively, was 90, 12, 0 ; 56, 101, 1 ; and 0, 2, 5. In most of the breeds studied there were equal numbers of pigs with 27 and 28 vertebrae, but English Saddleback × Improved Landschwein included a larger number with 28 vertebrae. All the pigs with 29 vertebrae were in a single litter of the Schwäbisch-Hällisch breed.

The correlation coefficient between number of vertebrae and body length was $r = + 0{\cdot}338$, a low value. The correlation between the average length of the vertebrae and body length was higher, $r = + 0{\cdot}893$. The regression coefficient between body length and vertebral length also showed that body length in pigs depends more on the length than on the number of vertebrae.

MUTTI, R. J. **Adequacy of protein in swine rations in Illinois, as related to areas within the state, phases of production, size of enterprise, share of income from swine sales, soil association, tenure, and the market for protein supplements.** *Univ. Illinois Agric. Exp. Stat. Bull.* No. 599, February 1956, pp. 31.

A farm survey was made to ascertain the levels of protein given to pigs in Illinois and also to find out whether insufficient protein was associated with size of enterprise, percentage of income from sale of pigs, soil type or farm tenure.

In the areas studied, about half the farmers gave rations adequate in protein, nearly one-third rations with up to 3 per cent. too little, and one-sixth even less adequate rations. The adequacy of protein feeding for different classes of pig and in different seasons varied between different areas within the state, but a 27 per cent. increase in the amount of 35 per cent. protein supplement used would be required to make up the average deficiency for all areas.

Generally, greater protein deficiencies were encountered in the small herds and when sales of pigs represented less than 20 per cent. of the gross farm income. The effects of type of farm tenure and of soil type varied widely between the different areas in the state.—I. A. M. Lucas.

GOATS, RABBITS AND OTHER MAMMALS

5292

TORTORELLI, N. Esperienze di lattazione artificiale in giovani capre. [**Artificial induction of lactation in young goats.**] *Riv. Zootec.*, 1956, **29,** 149–154. [Ovile Naz., Foggia.]

Artificial lactation was induced within 2 to 15 days in 12 of 13 goats of different breeds, about a year old, by a single subcutaneous injection in the neck of 1·5 mg. foralactol, a synthetic oestrogen, followed by daily massage of the udders. A second injection after 15 days was successful with the goat which did not respond at first. Daily milk yields ranged from 15 to 900 g., and total yields in 160 to 170 days from 13·2 to 103·6 kg. Best yields were from the goats which responded most readily to treatment. The milk obtained was normal according to chemical analysis, and was successfully used for processing into cheese and "ricotta". No ill effect was seen in the goats, which developed well, and were served, towards the end of lactation, by the same male. Twelve of the goats conceived immediately. Records will be kept through the subsequent gestation and lactation, to see what relation there is between production in induced and natural lactations.

The literature is reviewed and the advantages of induced early lactation are discussed. The study is considered of special importance since the goat population in Italy is increasing, but rearing practices leave much to be desired. The tendency is to mate the goats too young, at 7 to 8 months old, so that a long unproductive period is avoided, but this prejudices the animal's development and shortens her productive life. By inducing articificial lactation this situation can be avoided.—T. D. Bell.

THACKER, E. J. **The dietary fat level in the nutrition of the rabbit.** *J. Nutrition*, 1956, **58,** 243–249. [U.S. Plant Soil Nutrit. Lab., Agric. Res. Serv., Ithaca, N.Y.]

Groups of young Dutch belted rabbits were fed to appetite for 15 weeks on diets containing different amounts of fat, consisting of crude casein 25, Ruffex 10, maize oil 2, mineral mixture 5·1 and hydrogenated vegetable oil ("Primex") 3, 8, 13, 18 or 23 per cent., with dextrin to 100 and a vitamin supplement in proportion to the energy value of each diet. Thus the diets contained 5, 10, 15, 20 or 25 per cent. fat; an additional group were similarly fed on commercial pellets containing 3·77 per cent. ether-extractable matter. The animals were housed individually; feed consumption was measured daily and they were weighed weekly.

The rabbits which were fed on the diets containing 10, 15, 20 and 25 per cent. fat showed similar bodyweight gains; the animals given the commercial pellets also showed weight gains which were not statistically different from those found on the semi-synthetic rations, though nearly twice as much of the pellet diet by weight was required to produce each g. gain as was required with the 25 per cent. fat diet. The animals fed on the diet containing 5 per cent. fat gained about 200 g. less than those in the other groups.—G. A. Garton.

ANDO, N., KOJIMA, M., HETSUKA, K. and SERA, H. **Studies on the meat and by-products (46-48). Rabbit part: 12. Effect of castration on body weight gain and dissecting yield of fattened rabbit. 13. Effect of castration on the chemical composition of meat of fattened rabbit. 14. Effect of castration on the distribution of nitrogen in meat of fattened rabbit.** *Bull. Fac. Agric. Univ. Miyazaki*, 1956, **1,** 237–242; 242–244; 244–246. [Lab. Chem. Technol. Animal Products, Fac. Agric., Univ. Miyazaki.]

12. Male rabbits were castrated at 9, 17 or 29 weeks of age, or left intact, and slaughtered at 36 weeks old. They were fed alike throughout, during the last 42 days on a fattening ration. Castration at any age did not affect total weight increase or dressing percentage. There was more superficial and kidney fat in the castrated animals, but other carcase characteristics were unaltered.

13. Lean meat trimmed of fat from the castrated rabbits had a higher content of ether extract than that of the intact rabbits. The energy value of the meat and the proportion of water-soluble protein were also increased by castration.

14. In the meat of castrated animals, water-insoluble N was less and water-soluble N, except in the amino form, was more.—T. D. Bell.

GREIG, J. R. **The sheep dog. Management and feeding.** H.M.S.O., Edinburgh, 1956, pp. 16. Price 1s. 3d. net.

The sheep dog may travel as much as 100 miles a day during the lambing season, and it is always active. It is essential that it be adequately fed both quantitatively and qualitatively. A survey

in Wales, England and Scotland (Abst. 3722, Vol. 23) showed that sheep dogs are not usually in a good state of health. The diets commonly given are monotonous and unbalanced, deficient in Ca, nicotinic acid and sometimes riboflavin and vitamin D. The general principles of nutrition are discussed and correct diets for pregnant and nursing bitches, growing pups and working dogs are described. Variety is important, and the use is advocated of fish liver oils, animal protein and milk and fats to avoid the usual deficiencies of a monotonous diet of oat- or maizemeal.—T. D. Bell.

5297

HOLZWORTH, J. **Anemia in the cat.** *J. Amer. Vet. Med. Assoc.*, 1956, **128,** 471–488. [Angell Mem. Animal Hosp., Boston, Mass.]

Anaemia due to acute blood loss is rare ; haemolytic anaemia due to an infection was common, with a low rate of production of red cells. Nutritional deficiencies are not obviously present but further investigation of the nutrition of the cat might show it to be important.—T. D. Bell.

VORONOV, A. G. O metodakh polevogo izucheniya kormogo ratziona melkikh gryzunov. [**On methods of field study of the food of small rodents.**] *Byull. Mosk. Obshch. Prirod. Otdel Biol.*, 1955, **60,** No. 5, 21–30.

A survey was made of the main methods of investigation used by different workers to study the amount and quantity of food eaten by small rodents. Included were : the quantitative composition of the foods, daily amounts eaten, chemical composition, effect of rodents on plants, and soils, the daily feeding rhythm, habits of the rodents, changes in the food in relation to external factors and the physiological condition of the animal, and effect of the quality and quantity of food on reproduction.

In some of these investigations the animals were studied under both laboratory and field conditions. It is suggested that reliable results can be obtained only by investigations which include all these methods, as they are mutually complementary.—H. Scherbatoff.

POULTRY

GROWTH AND FATTENING

5299

ACKERSON, C. W. and MUSSEHL, F. E. **Growth of chicks as influenced by degree of confinement and level of feed intake.** *Poultry Sci.*, 1956, **35,** 483–485. [Dept. Biochem. Nutrit., Univ. Nebraska, Lincoln.]

Variations in growth rate caused by different rates of feed intake were studied by allowing groups of day-old chickens to eat to appetite up to 900 g. in all ; consumption in other 3 groups was restricted to 90, 80 and 70 per cent. of the amount consumed daily by the first group until each group had also consumed 900 g. One series were fed in individual cages and another in battery brooders. Chickens on the 70 per cent. restricted diet took 6 days longer to consume 900 g. feed. The enforced restriction produced no difference in rate of gain, but the standard error of the mean weight of the chickens in the individual cages was only about 4 g. while in battery-fed chickens it was 12 g., indicating that smaller significant differences can be detected by individual feeding.—J. S. Thomson.

MARGOLF, P. H. and WASHKO, J. B. **Seven years of managed turkey grazing : 75 to 150 birds per acre.** *Pennsylvania Agric. Exp. Stat. Bull.* No. 608, October 1955, pp. 9.

A cocksfoot and ladino white clover pasture established in 1944 was used in trials each year from 1945 to 1951. Turkeys were kept on the pasture from spring to autumn of each year at 2 rates of stocking : half of the pasture had 50 birds per acre and half 100 birds per acre in 1945, and in the other years the rates were increased to 75 and 150 birds per acre. Shelters and feeders on the pastures were moved daily to ensure even cropping and distribution of droppings.

During the trials the ladino clover declined rapidly, and by 1948 only cocksfoot remained under both rates of stocking.

Mortality was not high, and there was no evidence that infection had built up either through the years or during the season. Bad weather and inadequate protection in the first year, when mortality was highest, caused an outbreak of blackhead, but infection did not persist.

The birds were put on the pasture at from 6 to 15 weeks old and removed at about 32 weeks old. At the younger ages they were unable to take full advantage of the abundant early growth of grass, and at the older ages they attained sexual maturity, which was deleterious to market quality, before removal from the pasture.

From the light grazing the weight of live turkey produced per acre was from 531 to 1106 lb., and from the heavy from 911 to 2198 lb. The greatest reason for variation at either rate of grazing was

the actual number of birds in each separate year. It was apparent that the pasture could maintain the heavier rate of stocking. Consumption of feed per lb. gain, as mash and grain, was similar for both.—T. D. Bell.

McCartney, M. G. **The effect of day-length on rate of growth, feed conversion, feathering and market quality of turkeys.** *Poultry Sci.*, 1956, **35,** 468–475. [Dept. Poultry Husb., Pennsylvania State Univ., University Park.]

In each of 2 experiments one group of turkeys had an experimental day-length of 13 hr., and another natural daylight, all at normal environmental temperature. In each experiment the birds were reared together from hatching until the experiments began. In experiment 1 the birds were White Hollands, and the natural daylight was 12 hr. at the beginning, falling to 9 hr. between 13 and 28 weeks of age. In experiment 2, with Beltsville Small Whites, the natural day-length increased from 12 to 15 hr. between 12 and 24 weeks of age.

In each experiment the birds getting the longer daylight, experimental day in the first, and natural day in the second, were significantly heavier at the end of the trial, and efficiency was better. It is suggested that a day-length of at least 13 hr. and probably 15 hr. is required for maximum growth of turkeys, and birds maturing in autumn and winter would benefit from artificial light.

Feathering and market quality were not consistently affected by the conditions imposed.

Mały, F., Małowa, M. and Filusowa, F. Zużycie pasz przy wychowie kurcząt rasy Sussex do 6 miesiąca życia. [**Feed consumption of Sussex breed chicks up to the age of 6 months.**] *Rocz. Nauk rol.* [*B*], 1955, **70,** 181–196. [Inst. Zootech., Cracow.] Russian and English summaries.

The trial was made under unfavourable weather conditions, but the chickens developed satisfactorily as regards weight increases and attainment of maturity and reached average weights for pullets and cocks of 2038·6 g. and 2687·2 at 26 weeks and 55 per cent. of the pullets laid their first egg at between 181 and 230 days.

Feed consumed per head by pullets and cocks, respectively, during the breeding period was; grain 5·05, 5·87; concentrates 12·02, 17·07; green fodder 0·83, 0·75; skimmed milk 1·16, 0·90 kg., giving 2290 and 2950 g. digestible protein and 16·7 and 20·8 feed units. These quantities represented more green feed and skimmed milk than usual. The necessity for the high feed intake was attributed to the unfavourable conditions; in spite of the cost the trial was considered economically sound. (From English summary.)—T. D. Bell.

Sunde, M. L. **A relationship between protein level and energy level in chick rations.** *Poultry Sci.*, 1956, **35,** 350–354. [Dept. Poultry Husb., Univ. Wisconsin, Madison.]

Rations containing 20 or 28 per cent. crude protein were supplemented with 0, 5 or 10 per cent. white grease to vary the energy levels in trials with chickens from day-old to 4 weeks and from 4 to 10 weeks. At the lower protein level, increases in energy did not consistently affect growth to 4 weeks or to 10 weeks. At the higher protein level growth was improved by 5 per cent., and more by 10 per cent. added fat. The improvement was more marked at 10 than at 4 weeks. Without added fat the growth rate on 28 per cent. protein was less than that on 20 per cent. protein.

Efficiency of feed conversion was improved by raising levels of fat with each level of protein. Without added fat efficiency was better on the low- than on the high-protein level, but high protein and high energy combined were better than low protein without fat. When the results were plotted graphically it appeared that a change in protein level caused a change in the optimum ratio of energy to protein.—T. D. Bell.

Fisher, H. and Weiss, H. S. **Feed consumption in relation to dietary bulk and energy level: the effect of surgical removal of the crop.** *Poultry Sci.*, 1956, **35,** 418–423. [Poultry Dept., Rutgers Univ., New Brunswick, N.J.]

A basal ration supplemented with cerelose, or fibre and maize oil, to give total rations of equal energy value and protein percentage gave similar weight increases and efficiency of feed utilisation in a trial with 7-day-old chickens lasting 19 days. The same level of fibre but with cerelose instead of maize oil, and reduced energy, gave similar growth, but more feed was required. Similar results were obtained in a trial with rations supplemented with cerelose, maize oil, fibre, maizemeal or ground oats. It was concluded that feed intake was controlled partly by bulk, and not solely by energy intake.

Surgical removal of the crop from 3-week-old chickens is described. It was a simple operation and the birds soon recovered and have been raised to maturity without ill effect.

Trials with birds from which the crops had been removed, using rations similar to those in the first trial, showed that the operation did not affect feed consumption.—T. D. Bell.

WEST, J. W. **Degossypolized cottonseed meal as a substitute for soybean oil meal in a turkey growing mash.** *Poultry Sci.*, 1956, **35,** 304–307. [Mississippi Agric. Exp. Stat., State College.]

Solvent-extracted cottonseed oilmeal free of gossypol was used for turkeys to replace completely or partly the soya bean oilmeal in a growing and finishing mash containing about 20 per cent. protein. Eighty birds in each of 6 groups were given mash and grain to appetite from 8 to 28 weeks of age. There was no significant difference between any of the groups in growth rate, efficiency, uniformity or mortality. A non-significant, but constant, difference in favour of combinations of the meals, compared with either meal separately, suggested that they had some complementary action.

T. D. Bell.

KIRCHGESSNER, M. Die Verwendung von Leinexpeller in der Kükenaufzucht. [**Use of expeller process linseed meal in rearing chicks.**] *Arch. Tierernährung*, 1956, **6,** 55–60. [Inst. Tierernährungslehre, Landw. Hochsch., Hohenheim.]

Six groups of from 27 to over 50 day-old White Leghorn cockerels were fed to appetite for 10 days on a ration of barley 15, wheat 15, oats 15, maize 10, weatings 10, expeller process linseed meal 13, groundnut extraction meal 8, lucerne meal 5, wheat germ 5, sesame extraction meal 2, Protektor Konzentrat 2 per cent., believed to be adequate in amino acids except for lysine and methionine; or the same with lysine or methionine or both raised to requirement, plus 1 per cent. Aprofa, equivalent to 0·7 mg. vitamin B_{12} per cent.; or the same with the lysine and methionine supplements but no vitamin B_{12}. A control group had a practical ration. The results were analysed statistically. Growth and feed utilisation on all the experimental rations were extremely poor.

Another experiment, in which 7 groups of cockerels aged 30 days were given mixtures of the practical ration with 10 per cent. of maize, sesame meal, lucerne meal, wheat germ, weatings or groundnut meal, or 15 per cent. of linseed meal, confirmed the depressing effect of the last, though feed utilisation was less affected than in the younger chicks.

In a third experiment groups of 8-week-old chickens had the practical ration with 3, 5, 8, 10, 15 or 20 per cent. linseed meal. Again weight gain and feed utilisation were impaired, significantly so with over 10 per cent. linseed meal, and utilisation of total nutrients and digestible protein was impaired with only 5 per cent.—W. M. Deans.

5308

ROSENBERG, M. M. and PALAFOX, A. L. **Response of growing and mature pullets to continuous feeding of cane final molasses.** *Poultry Sci.*, 1956, **35,** 292–303. [Dept. Poultry Sci., Univ. Hawaii, Honolulu.]

New Hampshire chickens 6 weeks old, which had been reared to that age on rations containing different levels of molasses from 0·0 to 34·5 per cent. in a previous trial (see Abst. 5923, Vol. 25), were kept on grower rations containing the same percentages of molasses to 24 weeks of age, and then on layer rations, still with the same percentages of molasses, to 72 weeks. Each level of molasses was investigated in triplicate.

Growth to 24 weeks of age was satisfactory on levels of molasses up to 16·5 per cent. in one trial and 11·5 per cent. in the other 2. At the highest level, 34·5 per cent., there was a significant fall in growth rate. More feed was required to produce 1 lb. weight increase with each successive rise in molasses, but cost was reduced. Onset of maturity and rate of lay were not adversely affected by the experimental rations.

From 24 to 72 weeks of age egg production, egg size, incidence of blood spots, shell formation, mortality or feed required to produce a dozen eggs were not prejudiced by the level of molasses in the ration. Cost of feed per dozen eggs was inversely related to the level of molasses. Liveweight increase was progressively decreased by molasses at 7·5 per cent. and over, and concentrations of 16·5 per cent. and over increased the percentage of soiled eggs. The possibility that some of the observed differences were due to the high mineral content, up to 7·07 per cent., of the rations, or to slight differences in the energy supplied, is discussed.—T. D. Bell.

5309

BALLOUN, S. L., DONOVAN, G. A. and PHILLIPS, R. E. **Trichorethylene-extracted and expeller-type meat scraps and tallow in the diets of young chickens.** *Poultry Sci.*, 1956, **35,** 163–167. [Dept. Poultry Husb., Iowa State Coll., Ames.]

In 5 experiments it was shown that either expeller-type or trichloroethylene-extracted meat scraps at levels of 5 or 10 per cent. in the ration improved chick growth up to 4 or 8 weeks compared with a standard soya bean oilmeal type of

ration. Trichloroethylene-extracted meat scraps at a level of 20 per cent. could be given up to 12 weeks of age without impairing growth or efficiency of feed utilisation. There was no difference between the 2 types of meat scraps. Tallow as 2 or 4 per cent. of the ration also improved growth, but the effect was not so great when meat scraps were included in the ration. Tallow also improved efficiency.—T. D. Bell.

5310

YACOWITZ, H., CARTER, R. D., WYNE, J. and MCCARTNEY, M. G. **Effects of varying protein and fat levels in a finishing ration for turkey broilers.** *Poultry Sci.*, 1956, **35,** 227–229. [Dept. Poultry Sci., Ohio Agric. Exp. Stat., Wooster.]

Turkeys were fed from 8 to 16 weeks of age on rations containing 20, 23 or 26 per cent. protein, with or without 3 or 6 per cent. stabilised animal fat. At 16 weeks of age there were significant increases in weight, due to the added fat, on each protein level in males, but not in females. There was no significant difference between protein levels, and carcase quality was not affected. Feed efficiency also was improved by fat, but not by raising the protein level.—T. D. Bell.

5311

DAVIDSON, A. L. **Fat in poultry nutrition. 1. The chick from hatching to five weeks of age.** *J. Sci. Food Agric.*, 1956, **7,** 240–244. [Biol. Testing Stat., British Cod Liver Oils (Hull and Grimsby), Ltd., Hull.]

1. The first experiment reported showed that maximum growth and efficiency of chicks to 5 weeks of age was obtained on a ration in which the ratio of total digestible nutrients (TDN) to crude protein was between 3·5 and 4·0 to 1. In 2 further experiments this was confirmed, and it was demonstrated that, provided the ratio of TDN to crude protein was kept at the optimum level, improved performance was obtained by including higher levels of fat in the ration. All the experiments were on groups of 25 Rhode Island Red × Light Sussex cockerels, with a basal mixture of ground wheat, barley and oats; white fishmeal supplied the protein, and the fat was a blend of cod liver oil and vegetable oil.—T. D. Bell.

5312

SUNDE, M. L. **The effect of fats and fatty acids in chick rations.** *Poultry Sci.*, 1956, **35,** 362–368. [Dept. Poultry Husb., Univ. Wisconsin, Madison.]

In experiments with day-old chicks, growth to 4 weeks was not affected by supplements of white, brown or yellow grease, tallow, commercially stabilised fat or hydrogenated fat. Efficiency of feed utilisation was improved by all except the hydrogenated fat. Oleic, linolenic, linoleic and butyric acids improved feed utilisation but not rate of gain. Butyric acid depressed rate of gain. Stearic acid was without effect, and the addition of dispersing agents did not improve utilisation of the stearic acid. Tall oil, a by-product from the wood-pulp industry, crude tall oil and rosin acid extract of tall oil all depressed growth rate and efficiency in the order given.

Supplements of 5 per cent. white grease improved equally the efficiency of utilisation of high- and low-energy basal diets. When rations with and without fat supplements were offered to chickens either day-old or 31 days old, in a cafeteria system, the birds chose about twice as much of the supplemented ration.—T. D. Bell.

5313

CURTIN, L. V. and RAPER, J. T. **Feeding value of hydrolyzed vegetable fats in broiler rations.** *Poultry Sci.*, 1956, **35,** 273–278. [Buckeye Cotton Oil Company, Cincinnati, Ohio.]

Hydrolysed cottonseed fat, distilled cottonseed fatty acids, distilled animal fatty acids and animal fats were added to a basal ration containing 20 per cent. protein given to chickens from day-old to 8 weeks. They were added at rates up to 6 per cent. of the ration. The additions produced weight gains comparable to those of untreated birds, and improved feed utilisation. The highest rate, 6 per cent., was not better than 4 per cent. The hydrolysed vegetable fats containing 87 per cent. or more free fatty acids gave the most satisfactory improvement.—T. D. Bell.

5314

SUPPLEE, W. C., COMBS, G. F. and ROMOSER, G. L. **Failure to obtain growth responses with thioctic acid in chicks from different sources.** *Arch. Biochem. Biophys.*, 1956, **61,** 140–143. [Poultry Dept., Univ. Maryland, College Park.]

Groups of chickens of different breeds and with different diet histories were fed on either purified diets or on a practical starter diet to which 0·5 or 1·5 mg. thioctic (lipoic) acid had been added. Over a period of from 21 to 23 days there was no effect, as compared with controls, on either rate of gain or efficiency of feed conversion. The result was not in agreement with that of DeBusk and Williams (Abst. 5384, Vol. 25).—J. S. Thomson.

5315

MOELLER, M. W. and SCOTT, H. M. **Effect of equalized feed intake on the response of chicks to fish meal.** *Poultry Sci.*, 1956, **35,** 491–492. [Illinois Agric. Exp. Stat., Urbana.]

Day-old chickens were fed for 7 days on a pre-test ration. From 7 to 21 days groups of paired chickens were then fed individually on a test ration or the same ration with 10 per cent. fishmeal replacing an equivalent amount of cerelose. In one series the ration was fed to appetite, in the other feed intake was equalised. In both series fishmeal increased the rate of growth significantly, by 17·5 per cent. when feeding was to appetite and by 9·4 per cent. when feeding was equalised, indicating that fishmeal improved the quality of the test ration independently of its effect on feed consumption.—J. S. Thomson.

5316

ARSCOTT, G. H. **Complexity of a chick growth response to egg yolk, animal fat and fish solubles additions to the diet.** *Poultry Sci.*, 1956, **35,** 338–342. [Dept. Poultry Husb., Oregon State Coll., Corvallis.]

From day-old to 4 weeks of age chicks were given a semi-purified basal ration believed to be complete in all nutrients, and experimental groups were given supplements of 4 or 8 per cent. fish solubles, 4 or 8 per cent. stabilised animal fat or 4, 8 or 12 per cent. dried egg yolk, or combinations of the 4 per cent. levels of the solubles and fat, with or without 8 per cent. dried egg yolk, or either 4 per cent. solubles or 4 per cent. fat with 8 per cent. egg yolk.

The growth response to 4 and 8 per cent. fish solubles or animal fat was similar, and was not improved when the two were combined. Four per cent. dried egg yolk also produced a similar growth response, but with this supplement the response was greater as the level rose. The response to 8 per cent. dried egg yolk with 4 per cent. animal fat was significantly better than the response to animal fat alone. The complexity of the problem of the growth factors investigated is discussed.—T. D. Bell.

5317

HOPPER, J. H., SCOTT, H. M. and JOHNSON, B. C. **The growth promoting ability of fluid egg yolk.** *Poultry Sci.*, 1956, **35,** 195–197. [Illinois Agric. Exp. Stat., Urbana.]

When given as 5 or 10 per cent. of either practical or purified rations for growing chickens from day-old for 28 days, egg yolk improved weight gains during the last 14 days. The egg yolk, 5 per cent., was given also in combination with liver powder, fish solubles or whey, and these supplements were given alone to some groups of birds. The results indicated that egg yolk lacked the " whey factor " and it is suggested that its growth-promoting effect is due to its containing the " fish factor ".—T. D. Bell.

5318

LILLIE, R. J., SIZEMORE, J. R. and DENTON, C. A. **Feather meal in chick nutrition.** *Poultry Sci.*, 1956, **35,** 316–318. [U.S. Dept. Agric., Agric. Res. Serv., Animal Poultry Husb. Res. Branch, Beltsville, Md.]

In a trial with day-old New Hampshire chicks reared to 10 weeks of age, feather meal could replace part of the fishmeal, maintaining the same level of animal protein in the ration, without affecting growth or efficiency. A second experiment confirmed these results, but it was also found that the feather meal could replace all the fishmeal satisfactorily, and the combination of the 2 gave better growth than either separately.

In a third experiment a significant growth response was obtained by fish solubles at the 6 per cent. level or by feather meal at levels of 2·5 or 4 per cent. when added to a ration considered complete in all required nutrients. It is concluded that feather meal is a source of unidentified growth factor (see next Abst.)—T. D. Bell.

5319

MENGE, H., LILLIE, R. J., SIZEMORE, J. R. and DENTON, C. A. **An unidentified mineral required by the chick.** *Poultry Sci.*, 1956, **35,** 244–245. [Agric. Res. Serv., U.S. Dept. Agric., Beltsville, Md.]

Feather meal ash and feather meal, each as 4 per cent. of the ration of day-old chicks, stimulated growth equally up to 4 weeks, compared with a basal ration considered to be complete. It is suggested that the unidentified growth-stimulating factor in feather meal is inorganic in nature.

T. D. Bell.

5320

WISMAN, E. L., HOLMES, C. E. and ENGEL, R. W. **Chick growth response to condensed fish solubles and varying levels of terramycin.** *Poultry Sci.*, 1956, **35,** 457–462. [Virginia Agric. Exp. Stat., Blacksburg.]

Two experiments were made with day-old White Leghorn cockerels. In the first the basal ration contained no animal protein but was considered adequate in essential nutrients. Condensed fish solubles was added to the rations of half the birds, replacing 5 per cent. soya bean oilmeal. Terramycin hydrochloride was added to all rations at levels of 0, 10, 50, 100 and 200 mg. per lb. feed. The experiment was made in old quarters; in one series the droppings were removed and in another they accumulated. Growth data to 4 weeks showed that the presence or absence of droppings had no significant effect. Fish solubles in the ration had a marked stimulating effect. Terramycin at any level had no effect on growth with the basal ration, but with fish solubles there

was a significant effect at the highest levels of terramycin.

The second experiment was similar to the above except that the chickens were housed in either old or new quarters. Growth responses to fish solubles and terramycin were similar to those found in the first experiment. There was no significant effect of housing conditions.

J. S. Thomson.

5321

HAVERMANN, H. and HARTFIEL, W. Bestätigt der Röntgen-Test den Einfluss von Antibiotica (Terramycin) auf die Ca- und P-Aufnahme bei Küken? [**Does X-ray examination confirm the effect of antibiotics (terramycin) on the assimilation of Ca and P by chicks?**] *Arch. Geflügelk.*, 1956, **20,** 90–96. [Inst. Tierzucht, Univ. Bonn.] English summary.

The 240 chicks received for the first week after hatching a rachitogenic diet to make them use up their reserves of vitamin D_3 and then a similar diet with higher Ca and P contents, 0·53 and 0·45 per cent. in the first period and 1·44 and 0·99 in the next. The diet contained, per cent., maize-meal 60, soya meal 21·5, skimmed milk powder 10, lucerne meal 7, vitamin B concentrate 0·5, minerals and trace elements 0·5 and charcoal 0·5. After the first week the chickens were divided into 10 groups and given different combinations of terramycin and vitamin D_3. After 22 days of this treatment the right intertarsal region was X-rayed.

The calcification value derived by the method of Olsson (see Abst. 4104, Vol. 9) was improved by terramycin and rose both with increasing terramycin intakes of from 10 to 30 mg. per kg. feed and with increasing vitamin D_3 intakes of from 60 to 240 I.U. per kg. feed. Weight gains also were favourably influenced by terramycin.

5322

HEUSER, G. F. **Feeding high levels of antibiotics to chickens.** *Poultry Sci.*, 1956, **35,** 81–84. [Dept. Poultry Husb., Cornell Univ. Agric. Exp. Stat., Ithaca, N.Y.]

White Rock pullet chicks were given a basal ration and some birds received supplements of 10, 50 or 100 g. aureomycin or 100 g. terramycin per ton of feed for 12 weeks. The lowest level of aureomycin increased market weight at 12 weeks, and improved efficiency of feed conversion only slightly. Mortality was reduced. The higher levels of the antibiotics significantly increased market weight and feed conversion efficiency, and reduced mortality. From the 6th to the 8th week of the trial there was an outbreak of respiratory infection, and the effect of the high levels of antibiotics seemed to be enhanced thereby.

T. D. Bell.

5323

HAUSER, M. M., ANDERSON, G. W., PEPPER, W. F. and SLINGER, S. J. **Further evidence on the relation of coliforms to the growth response of chicks to antibiotics.** *Poultry Sci.*, 1956, **35,** 27–36. [Dept. Bacteriol., Ontario Agric. Coll., Guelph.]

Day-old chickens were kept for 17 days in a cleaned and disinfected environment. Some of the birds were given supplements of 10, 25, 100 or 200 p.p.m. chloromycetin. Bacterial counts of the intestinal contents of selected birds from each group were taken at 2 to 6, 6 to 13 and 13 to 17 days and weight gains and efficiency of feed utilisation were recorded for the remaining birds. Growth response to the antibiotic was slight, occurred mainly between 13 and 17 days, and was accompanied by an increase in intestinal coliform bacilli. Efficiency increased as the level of antibiotic rose, and corresponded to a progressive decrease in intestinal lactobacilli.

In a second experiment birds were kept for 35 days in an environment which had only been washed with cold water and not disinfected. Bacterial counts were made up to the 27th day, and feed efficiency and growth rates recorded. The supplements given were penicillin, aureomycin, terramycin, chloromycetin or sulphisoxazole, all 25 p.p.m., or 3-nitro-4-hydroxyphenylarsonic acid, 50 p.p.m. All supplements except sulphisoxazole stimulated growth, and the greatest stimulus was during the first week. The increased growth rate was accompanied by increase of intestinal coliform bacilli and reduction of enterococci. The lactobacillus counts showed no clear trend, and efficiency was not consistently improved. The relation between intestinal coliform bacilli and growth stimulation by antibiotics is discussed.

MCDONALD, M. W. **Feeding of detergents may have value in cockerel raising. Results of some early experiments.** *Agric. Gaz. N.S.W.*, 1956, **67,** 39–41. [N.S.W. Dept. Agric. Poultry Exp. Stat., Seven Hills.]

Two experiments are reported in which the effect of supplements of 6·6 p.p.m. procaine penicillin and 0·5 per cent. Na tetrapropylene benzene sulphonate, a detergent, on growth and efficiency of feed utilisation of chickens from day-old to 12 weeks in the first, and to 9 weeks in the second, experiment was investigated.

In the first experiment weight was 9 per cent. higher with penicillin and 6 per cent. higher with the detergent than that of controls getting no supplement. In combination the antibiotic and the detergent improved growth by 21 per cent. For each lb. liveweight increase controls required

4·10 lb. feed, compared with 3·80, 4·16 and 3·71 lb., respectively, for the groups getting antibiotic, detergent or both.

In the second experiment no supplement stimulated growth or improved efficiency. The antibiotic alone or in combination improved mortality rate in the first but not in the second experiment. These results agree with others published. The mode of action of detergents in promoting growth of chickens is discussed.

T. D. Bell.

5325

ISSAWI, H. F., KHISHIN, S. S. and HAFEZ, S. **Response of growth and dressing out percentage in imported breeds of cockerels to stilbestrol implantation in the subtropics.** *Poultry Sci.*, 1956, **35,** 85–92. [Dept. Animal Prod., Fac. Agric., Ein Shams Univ., Cairo.]

Blue Holland, Rhode Island Red, White Leghorn, Light Sussex and native cockerels were implanted with 15 mg. stilboestrol at 20 or 25 weeks of age. The birds were killed 13 weeks after implantation and dressing percentages were calculated.

Stilboestrol gave greater liveweight increases, compared with untreated birds, in Blue Hollands and Rhode Island Reds, and implantation at 20 weeks of age was more effective in this respect than it was at 25 weeks of age. In all breeds except the native the percentage yield of edible meat was increased by stilboestrol, which was more effective when implanted at the greater age.

KRATZER, F. H., DAVIS, P. N. and MARSHALL, B. J. **The protein and lysine requirements of turkeys at various ages.** *Poultry Sci.*, 1956, **35,** 197–202. [Dept. Poultry Husb., Univ. California, Davis.]

The crude protein and lysine requirements of turkeys were investigated in 12 experiments covering 4-week periods of growth from 4 to 24 weeks of age. Requirements of both decreased with age. At 4 weeks the necessary crude protein level was 23·5 per cent., and it fell regularly to 15 per cent. at 16 weeks, and more slowly to 13·5 per cent. at 20 weeks. The lysine requirements at the same ages were 0·92, 0·5 and 0·50 per cent. of the ration, or 3·90, 3·86 and 3·70 per cent. of the protein. Deficiency of lysine caused faulty feather pigmentation up to 12 weeks old, but not after that.—T. D. Bell.

5327

EDWARDS, H. M. (Jr.), NORRIS, L. C. and HEUSER, G. F. **Studies on the lysine requirement of chicks.** *Poultry Sci.*, 1956, **35,** 385–390. [Agric. Exp. Stat., Cornell Univ., Ithaca, N.Y.]

When a semi-synthetic diet was supplemented with lysine, to give lysine levels of from 0·7 to 1·2 per cent., maximum growth response from day-old to 4 weeks of age was obtained at the 0·9 per cent. level, but growth compared to that of controls getting a commercial starter was poor. In a ration in which protein was supplied by sesame meal the maximum response was with a lysine level of 1·1 per cent. The rations contained 20·5 per cent. crude protein. In 2 other trials maximum growth response to 6 weeks of age was obtained with a lysine level of 1·1 per cent., when growth was equal to that of controls getting a commercial starter mash. Maximum feed efficiency in all cases was obtained with 0·1 percentage unit more lysine than was maximum growth response. The reason for the requirements being higher than values suggested in the literature is discussed.—T. D. Bell.

5328

NEAL, W. M. **Cannibalism, pick-outs and methionine.** *Poultry Sci.*, 1956, **35,** 10–13.

Feather-picking and cannibalism (pick-outs) were reduced for several weeks in 2 flocks of growing Rhode Island Red chickens about 5 weeks old by giving a supplement of 1 oz. DL-methionine per cent. feed for 48 hr. In one flock the methionine supplement was continued, and pick-outs were almost completely eliminated. After 16 weeks of age feather-picking ceased in both flocks.

The flock not continued on methionine was given a ration of breeder mash 45 and oats 55 per cent., containing 0·20 per cent. methionine. The birds were in full production at 7 months of age, and there was no feather-picking from 16 weeks to 7 months. Picking started soon after 7 months. When 4 oz. methionine was given to 575 birds at each feeding picking stopped, and smaller amounts of methionine reduced the incidence. As soon as the supplement was withdrawn the picking began again.

The other flock did not receive any methionine supplement as mature birds. Picking in this flock was slight, which seemed to indicate that the birds had built up a reserve of the amino acid.

Production levels of over 80 per cent. were attained in both flocks although they were receiving only 0·20 per cent. total methionine, a level below that generally recommended.—T. D. Bell.

EVANS, R. J., BANDEMER, S. L. and BAUER, D. H. **Methionine and cystine requirements of chicks determined by calculation.** *Poultry Sci.*, 1956, **35,** 174–178. [Dept. Agric. Chem., Michigan State Univ. Agric. Appl. Sci., East Lansing.]

Available methionine and cystine in common poultry feedingstuffs were estimated by digestion

in vitro with trypsin and erepsin followed by microbiological estimation with *Leuconostoc mesenteroides*. The values found were then used to calculate the available methionine and cystine of diets reported in the literature. It was found that the requirement of growing chickens for available methionine plus cystine was between 0·22 and 0·46 per cent. of the diet, with 0·15 to 0·42 per cent. as methionine, values which agree well with the results of workers using carcase analysis and amino acid balance methods. The availability of methionine and cystine should be kept in mind when evaluating rations or estimating the requirements of chickens.

FISHER, H., DOWLING, J. (Jr.) and MADDY, K. H. **Low protein diets for turkeys raised under practical conditions.** *Poultry Sci.*, 1956, **35**, 239–241. [Rutgers Univ., New Brunswick, N.J.]

Up to 6 weeks of age turkeys were given rations containing 20 or 28 per cent. protein, from 6 to 12 weeks they had 16 or 20 per cent. and from 12 to 26 weeks 16 per cent. On each protein level some birds were given supplements of a methionine hydroxy analogue (calcium DL-2-hydroxy-4-methylthiobutyrate) and lysine hydrochloride in varying proportions.

In the first period growth was stimulated by the amino acids with 20 per cent. protein, but not with 28 per cent., and the advantage was maintained to the end of the trial. The growth of these birds was comparable to that of the turkeys getting 28 per cent. protein in the first 6 weeks. Amino acid supplements to the low-protein ration in the second period also produced results comparable to those obtained with the high-protein ration, which were unaffected by the supplement. When improved growth had been obtained up to 6 weeks of age there was no further stimulation. For low-protein rations of the types tested the estimated supplements required for satisfactory growth were : methionine hydroxy analogue from 0·05 to 0·5 and L-lysine from 0·1 to 0·4 per cent. of the ration.

ZNANIECKA, G., WODZINOWSKI, J. and KORZENIEWSKA, H. Porównanie wydajności wzrostowej, rzeźnej i mięsnej kur 4 ras popieranych i ich krzyżówek. 2. Wydajność nieśna zielononóżek, sussexów i ich obukierunkowych mieszańców. [**Comparison of the growth, meat yield and egg production on four breeds of chickens and their crosses. 2. Egg production of Polish Greenleg hens, Sussex and their reciprocal crosses.**] *Rocz. Nauk rol.* [*B*], 1955, **70**, 49–67. [Inst. Zootech., ZZD Pawłowice.] Russian and English summaries.

When Polish Greenleg and Sussex breeds were crossed either way they took less time to mature than the pure breeds, but not always significantly less than Polish Greenlegs, which are an early maturing breed. Winter laying was increased, as was total egg production on a hen-day basis. The efficiency of feed utilisation for egg production was improved, and there was no effect on the size of the eggs, broodiness or mortality of the hens. The liveweight of the crosses was greater than that of the Polish Greenlegs, the lighter breed. For commercial purposes crossing of Polish Greenleg and Sussex breeds is recommended. (From English summary.)—T. D. Bell.

ORR, H. L., HUNT, E. C. and SNYDER, E. S. **A comparison of dressing percentages and yield of edible cooked meat in five strains of turkeys as broilers and as mature stock.** *Poultry Sci.*, 1956, **35**, 333–338. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

The yields of Broad Breasted Bronze, Empire White, Beltsville Small White and 2 strains of Medium White turkeys at broiler weight, from 13 to 17 weeks of age, and maturity, 23 to 24 weeks of age, were compared. The rearing and treatment of all the birds was the same. Liveweight, dressed weight, ready-to-cook weight excluding neck and giblets, yield of edible meat and bone were recorded for the comparisons, and sex differences were also noted.

Males were heavier than females in both age groups, and had a higher percentage of bone. Females had higher percentages of dressed weight, ready-to-cook weight and edible meat than males, but the actual yields were less.

Broad Breasted Bronze broilers and mature birds had higher dressed weights as percentage of liveweights than Small and Medium Whites, and, in the mature birds, also than Empire Whites. Empire and Medium White mature birds were better than Small White. Ready-to-cook weight of broilers as percentage of dressed weight was

better in Small White broilers than in Empire and Broad Breasted Bronze. Between strains there was no significant difference in yield of edible cooked meat or percentage of bone, except for Small White, which had less bone than other strains. In mature birds Broad Breasted Bronze gave more edible cooked meat as a percentage of liveweight, but there was no difference in percentage of bone between strains. A higher percentage of edible cooked meat also was found in the mature birds than in the broilers, and the percentage of bone was less.—T. D. Bell.

5334

FROMM, D. and MARGOLF, P. H. **The effect of diethylstilbestrol on dressing and cooking losses of New Hampshire broiler-fryers.** *Poultry Sci.*, 1956, **35**, 254–256. [Dept. Poultry Husb., Pennsylvania State Univ., University Park.]

Diethylstilboestrol, 12 mg., implanted subcutaneously in 10 cockerels 5 weeks before slaughter at 13 weeks of age gave carcases with significantly higher dressing percentages than those of similar untreated birds. Total cooking losses in the treated birds were greater than in the untreated because treated birds lost more juice than untreated birds, and when this was allowed for the difference in favour of the untreated birds was not significant.—T. D. Bell.

5335

LEWIS, R. W., SANFORD, P. E., ERICSON, A. T. and CLEGG, R. E. **Effect of diet on the ether-extract content of chicken muscles.** *Poultry Sci.*, 1956, **35**, 132–137. [Dept. Poultry Husb., Kansas Agric. Exp. Stat., Manhattan.]

From day-old to 10 weeks of age chickens were fed on a purified diet low in fat, and experimental groups had this diet modified by the inclusion of maize, oats, barley, wheat, soya bean oilmeal or groundnut meal, or faeces. At 10 weeks of age ether extract in light and dark meat was estimated and the covering of subcutaneous, abdominal and neck fat was examined. Another group of birds got a standard high-efficiency ration from day-old to 8 weeks of age.

The type of diet significantly affected the percentage of ether extract of both types of meat. The low-fat purified diet gave greater deposition of fat in the muscles than did the diets modified with natural ingredients to contain more fat. Only the purified diet plus 10 per cent. faeces gave muscle with higher ether extract content than the purified diet without modification. The lowest ether extract content of muscle was produced by the maize modification, and the highest, next to the unmodified diet, by barley. In general there was more external fat when there was less muscle fat, except with groundnut meal.—T. D. Bell.

5336

LEWIS, R. W., SANFORD, P. E., ERICSON, A. T., HARRISON, D. L. and CLEGG, R. E. **Flavor and aroma of birds fed purified and standard diets.** *Poultry Sci.*, 1956, **35**, 251–253. [Dept. Poultry Husb., Kansas State Coll., Manhattan.]

With rations previously described (preceding Abst.), the effect of purified and natural diets on the quality of poultry meat was investigated. The birds were reared to 8 or 10 weeks old.

The diets modified with natural ingredients consistently and significantly improved the flavour and aroma of light and dark meat, broth and juice. The methods of assessment are described and it is considered that the diets used would be of value in further studies on the effect of diet on flavour of poultry.—T. D. Bell.

5337

SCHOETTLE, C. E., REBER, E. F., ALBERTS, J. O. and SCOTT, H. M. **A study of New Hampshire × Barred Columbian chicks from two days of age to ten weeks of age. 1. Growth; organ weights; liver fat and protein; femur and tibia fat and ash of chicks fed a ration free of antibiotics and coccidiostats.** *Poultry Sci.*, 1956, **35**, 95–98. [Dept. Vet. Physiol., Univ. Illinois, Urbana.]

From 2 days to 10 weeks of age the chicks were given a ration without antibiotic or coccidiostat. Five chicks were taken at 2 days and 1 week old and weekly thereafter, and gall bladder and bile, spleen, liver, femur and tibia were weighed. Percentages of protein and fat in the liver and of fat and ash in the bones were estimated.

The growth curve was linear, and average liveweight at 10 weeks was 1432 g. Weight of gall bladder plus bile, as a percentage of bodyweight, was not changed by age, and after a sharp increase in the first 3 weeks the same was true of spleen weight. Liver weight relative to bodyweight decreased steadily throughout the 10 weeks. The percentage of fat in the liver fell; that of protein rose sharply in the first week and then remained fairly constant. The percentage of fat and ash in the bones was not affected by the age of the birds.

EGG PRODUCTION

5339

GOWE, R. S. **Environment and poultry breeding problems. 2. A comparison of the egg production of 7 S.C. White Leghorn strains housed**

in laying batteries and floor pens. *Poultry Sci.*, 1956, **35**, 430–435. [Canada Dept. Agric., Ottawa.]

Chickens of 7 strains of White Leghorns were hatched and reared together to 160 days of age. From 160 to 500 days some of each strain were kept in batteries and some in floor pens with about 4 sq. ft. floor space per bird. All received the same laying mash to appetite. Mortality of the laying birds was significantly higher in pens than in batteries, and there were significant differences between strains in each location. Egg production estimated on the basis of number of hens originally in the hen-house and on the number surviving differed significantly within locations between strains, and between locations, and the interaction between location and strain was significant. Body-weight showed significant interaction between strain and location, and significant differences between strains and between locations. Egg weight was significantly different between strains only, and age at sexual maturity between strains and between locations. The importance of these findings for the commercial poultryman when selecting stock and choosing a system is discussed.

HUTCHINSON, J. C. D. **Control of seasonal variation in the egg production of hens.** *Nature*, 1956, **177**, 795–796. [Poultry Res. Centre (Agric. Res. Counc.), West Mains Rd., Edinburgh.]

Two groups of 21 Brown Leghorn pullets were given different lengths of artificial day. The control group had a constant day-length of 12 hr. throughout the experimental period of 42 weeks, and the experimental group had a day-length of 23½ hr. for the first 18 weeks, when they had been in lay for about 2 months, and then the period of light was gradually reduced during 8 weeks to 12 hr., where it was maintained. In the experimental group egg production was reduced and moulting increased by the reduction of day-length, compared with the controls, and recovery took about 2 months. In this trial environmental temperature was maintained at 64° F. Further investigations showed that reduction of temperature, to a minimum of 36° F., to simulate autumn and winter temperatures, in conjunction with shortening the day-length did not have any greater effect than the change in day-length alone. The same alterations of day-length with the experimental group in their second laying year completely stopped egg production.—T. D. Bell.

5341

DUBISKI, J. and CZYŻ, A. **Wpływ warunków oświetlenia na aktywność pokarmową kur. [The influence of light on the feeding activity of hens.]** *Rocz. Nauk rol.* [*B*], 1955, **70**, 31–47. Russian and English summaries.

Studies of 2 hens showed that, in winter, feeding began immediately it became light, and ceased some time before sunset. When artificial light was given, feeding began as soon as the light was put on. Extending the period of light in the afternoon had no effect, except to delay roosting.

With 2 groups of hens kept under the conditions of small farms, introduction of artificial light increased feed consumption by 4·3 to 18·6 per cent., depending on the way in which the light was prolonged. The most economical system was to give an extra 1½ hr. light at the end of the day. (From English summary.)—T. D. Bell.

HILL, F. W., ANDERSON, D. L. and DANSKY, L. M. **Studies of the energy requirements of chickens. 3. The effect of dietary energy level on the rate and gross efficiency of egg production.**

HILL, F. W. **4. Evidence for a linear relationship between dietary productive energy level and the efficiency of egg production.** *Poultry Sci.*, 1956, **35**, 54–59; 59–63. [Cornell Univ. Agric. Exp. Stat., Ithaca, N.Y.]

For previous parts see Absts. 5507, Vol. 24; 719, Vol. 25.

3. In the first experiment groups of 129 pullets in their first laying season were fed on rations supplying 740, 840 or 930 Cal. per lb., with 17·5 per cent. protein, for 11 months from October to August. During autumn, spring and summer egg production was not affected by the energy level of the ration. During the winter the rate of production was highest on the high- and lowest on the low-energy ration. Over the whole period the production levels for low-, medium- and high-energy levels were, respectively, 64·9, 66·9 and 68·1 per cent. The daily feed per 100 birds was 31·0, 28·9 and 26·1 lb. and the feed required per dozen eggs was 5·74, 5·19 and 4·60 lb. Weight changes of the pullets showed similar patterns, but total gains were 398, 458 and 516 g.

In the second experiment the energy levels compared were 945, 985 and 1025 Cal. per lb., with 16·5 per cent. protein, using groups of birds similar to those in the first experiment over a similar period. The extra energy of the 2 highest rations was supplied by adding 2½ or 5 per cent. industrial tallow. Again no difference was found in autumn, spring or summer in egg production. In winter production was higher as energy level rose. Over the whole period egg production in the groups getting 945, 985 and 1025 Cal. per lb. feed was, respectively, 66·5, 69·5 and 70·9 per cent.; feed per 100 birds daily was 25·6, 25·2 and 24·6 lb., and feed per dozen eggs was 4·62,

4·35 and 4·16 lb. Gains in liveweight were 113, 173 and 171 g.

4. From the results of the experiments reported above the relative efficiencies of the rations were calculated using the observed feed consumption and the feed consumption predicted by the partition equation of Byerly (*Maryland Agric. Exp. Stat. Bull.* A1, 1941) which takes into account bodyweight, weight changes and level of production. The relative efficiency was calculated as

$$\frac{100 \times \text{Predicted feed consumption}}{\text{Observed feed consumption}}.$$

The relative feed consumptions on rations supplying 740, 840, 930, 945, 985 and 1025 Cal. per lb. were 82·7, 90·5, 101·0, 101·7, 105·5 and 110·0. These values showed a linear relationship. The equation for the 4 lowest energy levels was $E = 11{\cdot}3 + 0{\cdot}96\,x$, where E = relative efficiency and x = productive energy of the rations in Cal. per lb. The importance of considering production level when evaluating the energy content of feeds in relation to efficiency is discussed.—T. D. Bell.

5343

Graton, A. and Poirier, R. Essai de trois formules alimentaires pour la ponte. [**Trial with three feed formulae for egg production.**] *Rev. d'Oka*, 1956, **30**, 1–4. [Inst. Agric. d'Oka, Canada.]

Three groups of 120 pullets each were used to compare different systems of feeding for egg production. The laying period of 310 days began when the birds were 6 months old. Group 1 was given grain and mash, 20 per cent. protein in the latter, in equal quantities, so that the total feed had 16 per cent. protein. Group 2 got an all-mash, high-energy ration with 20 per cent. protein and group 3 an all-mash, high-energy ration with 17 per cent. protein.

Heavier but fewer eggs were laid by group 2, and their efficiency of feed utilisation for egg production was inferior, 7·66 lb. feed per dozen eggs compared with 6·37 and 6·38 lb. in groups 1 and 3, respectively. Group 3 produced more eggs than group 1 and the size of the eggs was greater, little less than that in group 2. The importance of the grading of the eggs and the economics of the system are discussed.—T. D. Bell.

5344

Coles, R. **Observations on the occasional depressing influence of fishmeal on the hatchability of hens' eggs.** *J. Agric. Sci.*, 1956, **47**, 354–362. [Minist. Agric. Fish. Food.]

Four groups of pullets were given rations with the same crude protein level, well fortified with vitamins A and D_3. Group 1 got vegetable protein and synthetic vitamin B_{12}, group 2 vegetable protein and condensed fish solubles, group 3 white fishmeal 10 per cent. and group 4 white fishmeal 5 per cent. The vitamin B_{12} content of rations 1 to 3 was estimated to be 0·015 μg. per g., and of ration 4, 0·003 μg. per g. Percentage hatching was lower than expected and lower than usual in the flock. For groups 1 to 4, respectively, the hatchabilities were 74·2, 69·4, 54·7 and 56·8 per cent. Most of the embryonic mortality was about the 19th day of incubation. There was no heavy mortality in the early days of incubation, as is usual, and the peak in this case was not thought to be due to deficiency of vitamin A or E. It had been thought vitamin E might be deficient because of destruction in the fishmeal rations, but evidence for this was not found. The depression in groups 3 and 4 may have been due to a toxic substance in the fishmeal, which may occur only in certain batches or from certain sources, and may be the cause of occasional reductions in hatchability in flocks which normally have high records. Mortality to 12 weeks of age of the chicks hatched was less in the groups with high hatchability rates. This is discussed in relation to the effect of the fishmeal on hatchability.

T. D. Bell.

5345

Moreng, R. E. and Bryant, R. L. **Reproduction in turkeys as influenced by 4-nitro-phenylarsonic acid.** *Poultry Sci.*, 1956, **35**, 406–409. [Poultry Dept., N. Dakota Agric. Exp. Stat., Fargo.]

Addition of 4-nitrophenylarsonic acid to the drinking water of breeding turkeys decreased egg production but had no effect on hatchability and fertility of eggs or on mortality of the poults. The weight of the poults at hatching time was depressed but at 8 weeks of age there was no difference in weight.—J. S. Thomson.

5346

Adams, J. L. **A comparison of different methods of progesterone administration to the fowl in affecting egg production and molt.** *Poultry Sci.*, 1956, **35**, 323–326. [Poultry Dept., Univ. Wisconsin, Madison.]

There were 6 groups of 10 year-old hens as follows: group 1, untreated control; group 2, 110 mg. progesterone per kg. feed; group 3, 220 mg. progesterone per kg. feed; group 4, a single intramuscular injection of 50 mg. progesterone; group 5, a 33·4 mg. pellet of progesterone implanted in the neck; group 6, weekly intramuscular injections of 25 mg. progesterone.

Progesterone, however given, depressed egg production compared with controls, during the 12 weeks when observations were made, but bodyweights were not affected. In all groups except 4 and 5 rate of wing moult was increased, and in

this respect group 6 suffered most. Progesterone by mouth, in groups 2 and 3, was slower to take effect than by injection. Implanted progesterone also was slower to act than injected, but the effect lasted longer.—T. D. Bell.

5347

HEYWANG, B. W. **The effect of supplemental methionine in a corn-soybean diet for laying chickens.** *Poultry Sci.*, 1956, **35,** 462–468. [U.S. Dept. Agric., Agric. Res. Serv., Animal Poultry Husb. Res. Branch, Glendale, Ariz.]

In the first experiment pullets were given a basal ration of ground yellow maize and soya bean meal containing about 0·28 per cent. methionine and 0·56 per cent. cystine to which was added for other groups 0·05 or 0·085 per cent. DL-methionine or 5 μg. vitamin B_{12} per lb. feed, or combinations of these. In the second experiment 2 basal rations were used similar to the above but containing slightly less soya bean meal; one contained 2·5 per cent. fishmeal. Both rations had 5 μg. vitamin B_{12} per lb. added.

In neither experiment, over 252 and 215 days, did the additional methionine have a significant effect on weight gain, egg production, feed consumption per dozen eggs, egg weight or shell thickness. In the first experiment the hatch of eggs was increased by the addition of vitamin B_{12} but there was no additional effect when methionine was given along with vitamin B_{12}.—J. S. Thomson.

5348

HEUSER, G. F. **Feeding chemically treated seed grains to hens.** *Poultry Sci.*, 1956, **35,** 160–162. [Dept. Poultry Husb., Cornell Univ. Agric. Exp. Stat., Ithaca, N.Y.]

In the first trial, groups of 12 to 17 hens were given an all-mash ration containing 33⅓ per cent. treated sweet corn and 33⅓ per cent. untreated maize, and a control group got 66⅔ per cent. untreated maize. The fungicides used were: group 1, Ceresan M (7·7 per cent. ethyl-mercury-*p*-toluene-sulphonanilide, Hg 3·2 per cent.) freshly applied; group 2, Semesan Jr. (12 per cent. hydroxymercuricresol) applied 3 years previously; group 3 Arasan (50 per cent. tetramethylthiuram disulphide) applied 3 years previously; group 4 none; group 5, none.

There was no significant difference between groups 1, 2, 4 and 5 in bodyweight, mortality or egg production. In group 3 egg production declined, within 2 or 3 days, to 10 per cent. from its original level of 60 to 70 per cent. Removal of the treated grain from the ration caused an equally rapid rise in egg production to the previous level.

In the second trial group 1 got wheat treated 2 years previously with Improved Ceresan (5 per cent. ethyl-mercury phosphate, Hg 3·8 per cent.) as the grain portion of a grain and mash ration, about half of the feed intake being grain, and group 2 got untreated wheat. Egg production declined to about 25 per cent. on treated wheat, but more slowly than in group 3 in the previous trial.—T. D. Bell.

5349

SWANSON, M. H., WAIBEL, P. E., HELBACKA, N. V. and JOHNSON, E. L. **Shell egg quality as affected by Arasan in the diet.** *Poultry Sci.*, 1956, **35,** 92–95. [Dept. Poultry Husb., Univ. Minnesota, St. Paul.]

Arasan-SFX, a fungicide used in seed treatment and containing tetramethylthiuram disulphide, was added for 16 days to the ration of laying hens at levels rising from 10 to 200 p.p.m. Levels up to 50 p.p.m. reduced shell thickness and the quality of the albumin. At the highest level no hard-shelled egg was produced after 36 hours' treatment. Seven days after treatment ceased egg quality returned to normal.—J. S. Thomson.

5350

HILL, J. F. and NORDSKOG, A. W. **Efficiency of performance testing in poultry.** *Poultry Sci.*, 1956, **35,** 256–265. [Dept. Poultry Husb., Iowa State Coll., Ames.]

This is a study of differences in egg production and in mortality between different varieties of chickens, to see how such differences may vary between testing locations or from one year to another at the same place. Two sets of data were analysed, each consisting of hen-day egg production and mortality of all birds in each hen-house for groups of hens over a period of 348 days from 22 weeks of age. The first set of data covered groups of 55 different inbred-hybrid varieties each tested at 13 different locations in the same year, and demonstrated significant differences in performance both between locations and between varieties. The second set of data was from tests of 10 varieties at 4 locations in 3 consecutive years. A complication existed in that the 10 varieties were selected from a larger number of varieties on the basis of the performances in the first and second years, but it is argued that this probably had little effect on the conclusions. Estimates of variance components were obtained from the analyses and it was found for both measures that there was a larger interaction between varieties and years than between varieties and locations. It is concluded that more efficient variety comparisons are obtainable by replicating over years than over locations. Tests at one location over 3 years are likely to give results of the same accuracy as tests at 2 locations for 2 years or at 13 locations for a single year.—I. McDonald.

OTHER BIRDS

5351

SUNDE, M. L. and BIRD, H. R. **A critical need of phosphorus for the young pheasant.** *Poultry Sci.*, 1956, **35,** 424–430. [Dept. Poultry Husb., Univ. Wisconsin, Madison.]

Day-old Chinese Ring-neck pheasants were reared to 4 weeks of age on a basal diet containing 0·66 per cent. P, much of it as phytin P; other groups were given additions of 0·1, 0·2, 0·3, 0·4, 0·5 and 0·8 per cent. inorganic P. Growth on the basal diet was poor and weight differences were evident after only 1 week; mortality was high and leg weakness appeared in one week. Bone ash was only about 38 per cent. Growth and bone calcification were normal when 0·3 per cent. P was added to the ration. Larger amounts had no further appreciable effect on growth. On the assumption that 70 per cent. of the P in the basal ration was phytin P it is concluded that optimum performance was obtained when the level of inorganic P was 0·5 per cent. The early effect of P deficiency on growth and the early appearance of leg deformity should make the pheasant a good test animal in a study of the metabolism and availability of P.—J. S. Thomson.

5352

LAESSLE, A. M. and FRYE, O. E. (Jr.) **A food study of the Florida bobwhite *Colinus virginianus floridanus* (Coues).** *J. Wildlife Management*, 1956, **20,** 125–131. [Dept. Biol., Univ. Florida, Gainesville.]

The feeds most eaten by the bobwhite quail were sloughgrass (*Scleria muhlenbergii*) and wax-myrtle (*Myrica* spp.); preference was shown for the former. The sloughgrass nearly provided the "ideal" requirements of the birds for protein, Ca and P. In late autumn and winter, when wax-myrtle predominated in the diet, many birds were listless and unable to fly any considerable distance. A list of other feeds found in the crops of 375 birds, on which the study was based, is given.—T. D. Bell.

5353

ROSENE, W. (Jr.) **An appraisal of bicolor lespedeza in quail management.** *J. Wildlife Management*, 1956, **20,** 104–110. [U.S. Fish and Wildlife Serv., Gadsden, Ala.]

Trials in which bicolour lespedeza was planted in some areas and similar areas were left unplanted showed that the value of the legume was only as a feed for quail; it was of no use to supply nesting cover. Where other natural foods were scarce the population of quail rose on the planted areas, but not so when feed was adequate elsewhere. Some of the strips of lespedeza remained unused when unplanted areas provided ample feed. Only high quality plantings of lespedeza were of any value. In the main the planting o lespedeza did not increase quail population, though from the hunter's point of view it had the advantage of attracting birds during the winter, providing more concentrated sport. Crop analysis showed that bicolour lespedeza was a preferred feed of quail.—T. D. Bell.

5354

MRAZ, F. R., BOUCHER, R. V. and CALLENBACH, E. W. **The response of bobwhite quail to antibiotics.** *Poultry Sci.*, 1956, **35,** 76–80. [Pennsylvania Agric. Exp. Stat., University Park.]

Supplements to provide 10 g. per ton of feed of aureomycin, bacitracin, procaine penicillin, terramycin or streptomycin were given to groups of 60 quail chicks for 5 or 16 weeks. Growth at 3 weeks of age was stimulated significantly by the first 4 but not the last of the antibiotics. Thereafter the advantage in weight was lost, so that by 16 weeks of age birds not getting antibiotics were as heavy as any of the supplemented birds.

In a second experiment penicillin, bacitracin or terramycin was given at levels of 5, 10 or 20 g. per ton of feed to groups of 60 quail chicks for 6 weeks. Penicillin and bacitracin gave significantly better growth response at 3 weeks than terramycin, which was, in turn, significantly better than no antibiotic supplement. The advantages in weight were still present in this experiment at 6 weeks of age. There was no difference between the different levels of penicillin. With bacitracin the 2 higher levels were significantly superior to the lower, at both 3 and 6 weeks. With terramycin the highest level was significantly better than the medium, and the medium than the lowest at 3 weeks, but at 6 weeks the 2 lower levels were not different, but were significantly worse than the high level. In neither experiment did the antibiotics influence mortality, cannibalism or feather-picking.—T. D. Bell.

5355

SCHEMNITZ, S. D. **Wild turkey food habits in Florida.** *J. Wildlife Management*, 1956, **20,** 132–137. [Sch. Forestry, Univ. Florida.]

Analyses of the contents of 32 crops taken from wild turkeys in winter showed that 114 items of food altogether were eaten, but of these only 14

were present as more than 0·5 per cent. by weight of the total. The most important feed was live oak acorns, and other types of acorn in small quantities, followed by paspalum and panicum grass seeds. In each bird from 3 to 24 different types of feed were found, with an average of 8. Animal feeds, mainly grasshoppers and dragon-flies, represented 3 per cent. of intake.

In droppings taken throughout the whole year grass seeds and leaves were most abundant. Food in winter was mainly acorns, grass seeds and a few fruits ; in summer grass leaves and seeds preponderated. Animal feeds, grasshoppers and dragon-flies, were 3·6 per cent. of feed found. Maize was generally available in feeders. It was not eaten to any great extent, especially in autumn when abundant acorns were available, or in spring and summer when there was plenty of grass and grass seeds.—T. D. Bell.

5356

POKROVSKAYA, I. V. Materialy po pitaniyu gnezdovykh ptentzov lesnykh ptitz leningradskoi oblasti. [**Data on the feeding habits of nestlings of forest birds in the Leningrad region.**] *Zool. Zh.*, 1956, **35,** No. 1, 96–110. [Dept. Zool., Leningrad A.I. Gertzen Pedagogical Inst.]

Observations made on the following birds are given in detail : starling, jay, redwing, fieldfare, magpie, blackcap, lesser whitethroat, siskin, linnet.

The type of food in many cases depended on the weather, nesting time and site. The freshwater fauna of reservoirs was largely used by birds for feeding the nestlings. For several types of nestlings and adult birds, the change-over to feeding on insects which appear at a given time and in large numbers was characteristic. The birds were useful to destroy insect pests of trees and market garden crops.—H. Scherbatoff.

BONADONNA, T. Significato sociale ed economico della produzione zootecnica. [**Social and economic importance of animal production.**] *Zootec. Vet.*, 1956, **11,** 92–102. [Univ. Camerino.]

The world food situation is reviewed. With the technical advances already made and still possible, the existing shortages in some areas are regarded as a social, political and moral problem of distribution and organisation and co-operation between nations.

The paradoxical existence of regions of plenty and regions of want is a fact. In Italy, since such a world situation exists, the problem of over-production and excess of imports of food over exports should be met by organisation and regulation of animal, and all agricultural, production, improvement of quality, reduction of production costs by application of up-to-date technique, and education of the people to demand a better standard of feeding. The average consumption per head of protein, particularly animal protein, is lower than is desirable, and this could be rectified by planning and distribution combined with a programme of education on nutrition.

5362

WILLIAMS, H. T. **Silage in the economy of the farm.** *Agriculture, J. Minist. Agric. Engl.*, 1956, **63,** 1–5. [Seale-Hayne Agric. Coll., Newton Abbot.]

Calculations are presented which suggest that, of the common homegrown feeds, kale cut for feeding gives the highest profit per acre for milk production. Grazed grass comes second and grass silage third. In terms of profit per hour of labour required in crop production, grazing is the most profitable, followed by grass silage and kale. It is concluded that where land is the limiting factor, grazing and kale should be increased at the

expense of silage. Where land is relatively more plentiful than labour the emphasis should be on grazing, silage and kale in that order. Silage, however, is important in any grassland system as a means of conserving surpluses. It is unwise to grow large areas of roots (including kale) if their high labour requirements prevent conservation of grass and cause waste.—J. L. Corbett.

5363

MACKNESS, R. A. **Seasonality of beef and veal supplies in the United Kingdom.** *Empire J. Exp. Agric.*, 1956, **24,** 20–25. [Sch. Agric., Univ. Cambridge.]

In this introduction to a series of papers in which the problems posed by seasonal production will be examined it is shown that between 1940 and 1953 supplies of home-produced beef and veal had become increasingly seasonal, being highest in October and lowest in June. Despite the higher prices prevailing in June, producers were prepared to accept the lower prices prevailing in October because of the firmly established belief that cattle finished on grass were less costly to produce. Supplies of imported meat also show a seasonal pattern, maximum quantities arriving in October, the month of highest home production. It is suggested that the adoption of improved methods of feeding cattle in winter would enable producers to level out supplies.—J. N. Aitken.

5364

Nahrungsmittelausfall durch Tiererkrankung. [**Loss of food through animal diseases.**] *Lebensmittel u. Ernährung*, 1956, **9,** No. 4, 12–13.

The loss from carcases partly or wholly condemned on account of tuberculosis in 1952 was estimated at nearly 12 million Schilling and there were also estimated losses of production from diseased animals not coming to slaughter, of milk 46,000 metric tons and meat 3900 metric tons, value 73 and 58 million Schilling, respectively. For liver fluke in cattle the corresponding estimates were 5 million Schilling, milk 22,000 metric tons and meat 3200 metric tons, value 35 and 48 million Schilling. Mastitis is believed to cause a loss of 23,000 metric tons of milk, value 36 million Schilling. Allowing for other losses from contagious abortion, warble fly and intestinal worms, the total annual loss to Austrian agriculture from chronic disorders is estimated at 300 million Schilling.—W. M. Deans.

JEBE, E. H. and CLIFTON, E. S. **Estimating yields and grades of slaughter steers and heifers.** *J. Farm Econ.*, 1956, **38,** 584–596. [Iowa State Coll., Ames.]

It is important that the prices paid to producers of livestock should be a fair reflection of the values placed by the consumer on the meat, or meat products, which are obtained after slaughter and processing. Accuracy of pricing will encourage farmers to produce the proportion of the different weights and grades of animals that will meet to the fullest extent the consumer's demand. To show how accuracy might be improved an example is taken of the yields and grades estimated by one buyer for 219 steers and 74 heifers, analysed in relation to the actual yield and Federal carcase grade of each animal. The carcase gradings are put on a numerical basis by estimating to the nearest third of a grade and coding, so that the top third of the Prime grade scores 15 and the lower third of the Utility grade scores 1.

Linear regression analyses of actual yields and grades on estimated yields and grades lead to a number of conclusions regarding the errors of the particular buyer studied. Thus it is concluded that he tended to underestimate the yields of low-yielding steers and to overestimate those of high-yielding steers ; these errors tended to cancel each other and leave the average estimated yield close to the average actual yield. Conclusions of the same type are set out for heifers and for grade estimates. It is suggested that the regression equations obtained could be used for the adjustment of estimates, with a resulting reduction in the errors for individual animals.

A further analysis of the differences between actual and estimated yields and grades showed that there is a positive correlation between these for the buyer in question. Given a value equation, relating the value of the animal to its weight, yield and grade, the results of this analysis could be used to give the resulting errors in price paid to the producer. In a constructed example the standard deviation of these errors was found to be $15. In conclusion a number of suggestions are made for improving the pricing accuracy of livestock.

[Scatter diagram and conclusions drawn from regression analysis do not agree.]—I. McDonald.

5366

BLAGBURN, C. H. **Costs and profits in milk production.** *Agric. Rev.*, 1956, **1,** 29–34. [Univ. Reading.]

The factors influencing profits per gal. per cow and per acre are discussed with particular reference to a farm management survey made by the University of Reading. Farm-produced feeds, especially grass, are valuable for reducing costs per gal., giving economic increases in milk yields and increasing stock density. More efficient use of labour will reduce costs per gal. and permit increases in herd size.—J. L. Corbett.

5367
PACI, C. La crisi del latte sotto il profilo produttivistico. [**The milk crisis from the producer's viewpoint.**] *Riv. Zootec.*, 1956, **29,** 101–105.

The outward sign of the milk crisis in Italy is over-production relative to demand, and resulting low prices: fundamentally the trouble is that though production has increased since the war, the increase is mainly due to increased numbers of cattle, to a large extent imported. Milk yield per head is very low, about 400 gal. per cow per year, and compares unfavourably with that in other European countries. The cost of milk production per gal. is high, and only by improving yields can this unfavourable balance between price and cost be redressed.

Very few farms, only 2 per cent., record their milk yields. The introduction of this practice alone, with the consequent elimination from the herds of poor-yielding cows, better selection of replacements and reduction of waste of concentrates, would do a great deal towards overcoming the economic crisis as it stands. Further attention to animal health, the elimination of tuberculosis, estimated to be present in 55 per cent. of the cattle and causing from 10 to 25 per cent. reduction of production, and improvement of fertility by paying attention to nutritional deficiencies, are also necessary for the complete solution of the problem.—T. D. Bell.

MOLNAR, I. **Wheat and sheep production in the wheat belt.** *J. Austral. Inst. Agric. Sci.*, 1956, **22,** 51–56. [Soil Conservation Authority, Victoria.]

From surveys of farms in 3 areas of Victoria the relative returns from wheat and sheep, including lambs and wool, were assessed and compared. Recommendations are made for the areas in which wheat growing should first be restricted or prohibited should the necessity arise.—T. D. Bell.

5371
MAUNDER, A. H. **Economy in pig feeding.** *Farm Econ.*, 1955, **8,** 12–17. [Agric. Econ. Res. Inst., Univ. Oxford.]

The system of marginal analysis was applied to a number of pig feeding experiments taken from the literature. It was shown how marginal analysis could be applied in practice to ascertain the relation between profit, the number of pigs to be fattened and the weight to which they should be taken, when the price of feeds and market price of the pigs sold were considered. In short-term programmes overheads and labour were taken as constants and price of purchasing weaners was considered.—T. D. Bell.

5372
BOYSEN, H. Kan vi bli selvberget med brødkorn. [**Can we become independent in respect of bread cereals?**] *Tidsskr. norske Landbruk*, 1956, **63,** 79–88.

The accurate measurement of potentially arable land has many difficulties and it is costly to put new land under the plough. The planning of production for self-sufficiency in war time must imply certain surpluses in peace. Estimates are presented of how Norwegian agricultural land might be used to produce the bread cereals required.

DIET IN ETIOLOGY OF DISEASE

GENERAL

5373
BODA, J. M., CUPPS, P. T., COLVIN, H. (Jr.) and COLE, H. H. **The sequence of events preceding death of a cow in acute experimental bloat on fresh alfalfa tops.** *J. Amer. Vet. Med. Assoc.*, 1956, **128,** 532–535. [Dept. Animal Husb., Coll. Agric., Univ. California, Davis.]

Bloat occurred 40 min. after the cow started to graze lucerne at the flowering stage. Pressure in the rumen increased to 49 mm. Hg before rumen movement ceased. The highest pressure recorded was 74 mm. Hg 2 hr. after feeding started. Final collapse occurred when the pressure was 55 to 60 mm. Hg.

The cow ultimately became cyanotic and the rumen was tapped when breathing ceased but the pulse was still present, releasing free gas. Further opening of the rumen released a fountain of foaming digesta.—A. T. Phillipson.

BARRENTINE, B. F., SHAWVER, C. B. and WILLIAMS, L. W. **Antibiotics for the prevention of bloat**

in cattle grazing ladino clover. *J. Animal Sci.*, 1956, **15,** 440–446. [Dept. Animal Husb., Mississippi Agric. Exp. Stat., State College.]

Steers were selected on the basis of their susceptibility to bloat and allowed to graze a pure stand of ladino clover. The oral administration of chlortetracycline, oxytetracycline, bacitracin, and streptomycin gave no protection against bloat. A single dose of 25 mg. procaine penicillin prevented bloat in yearling steers for up to 3 days. Older steers required 50 to 75 mg. Pure potassium penicillin in equivalent amounts was equally effective. Protection against bloat was not immediate but was effective several hours after the penicillin had been administered.—J. N. Aitken.

FORD, C. M. **Nutritional factors and bovine infertility in the East Midlands.** *Brit. Vet. J.*, 1956, **112,** 177–188. [Vet. Invest. Lab., Sutton Bonington, Loughborough.]

An investigation of 150 herds with low fertility is reported. Of the herds, 35 per cent. showed signs of genital infection, and in 21 per cent. both genital infection and ovarian dysfunction were present. Where there was no infection ovarian dysfunction was generally considered to be of nutritional origin, and in a few of the herds there was obvious undernutrition. In most of the remainder imbalance or deficiency of Ca and P was found in the rations, and response could be obtained by correcting the mineral contents of the rations. The importance of trace elements, and the need to consider the mineral composition of common feedingstuffs such as kale, mangolds and hay, are discussed.—T. D. Bell.

5376

SCHÖNHERR, S. Die Unfruchtbarkeit der Ziegenböcke, ihre Verbreitung, frühzeitige Erkennung und Bekämpfung. [**Infertility of male goats, its extent, early recognition and control.**] *Ztschr. Tierzücht. Züchtungsbiol.*, 1956, **66,** 209–234; 381–416. [Tierklin., Freie Univ., Berlin.]

Infertility in male goats is a serious problem in Central Germany. Between 1950 and 1953, 1545 bucks were examined clinically, of which 280 were infertile and 281 had reduced fertility. A clinical description is presented. The infertility could not be related to feeding practices and most of the animals seemed to be in a good state of nutrition and general health. The cause of the trouble is not understood and requires more study.

BAUER, H. Die Wehenschwäche der Mutterschweine infolge Mangelfütterung wie Konstitutionsschwäche, und ihre Beziehungen zu Totgeburten und Aufzuchtsverlusten der Ferkel. [**Failure of uterine contractions of sows as the result of defective diet and constitutional weakness, and its relation to stillbirths and losses in rearing young pigs.**] *Züchtungskunde*, 1956, **28,** 189–204. [Tierhyg. Inst., Univ. Freiburg i. Br.]

In sows labour lasting more than 10 hr. is considered abnormal. Failure of uterine contractions is a more common cause of delay than obstruction. Götze (*Berl. tierärztl. Wochenschr.*, 1934, p. 849) considered that unbalanced diets low in protein were especially liable to produce K deficiency and failure of uterine contractions. Old sows are particularly prone, and tetany, eclampsia and deficiency diseases like rickets are predisposing conditions, but there is some ground also for suspecting a constitutional predisposition to lack of uterine tone. The relative importance of nutrition and hormone production is not understood. Longer pregnancy is correlated with longer labour, and the number of dead and weak piglets increases with length of labour.

A questionnaire was answered by 65 veterinary surgeons in different areas, about the relation between nutritional defects and failure of uterine contractions. All sorts of deficiencies were blamed, both excess and lack of protein, excess carbohydrate, mineral deficiencies and lack of vitamin A.

GARTON, G. A., DUNCAN, W. R. H., BLAXTER, K. L., MCGILL, R. F., SHARMAN, G. A. M. and HUTCHESON, M. K. **Muscular dystrophy of beef cattle and unsaturated fats.** *Nature*, 1956, **177,** 792–793. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

The suggestion that the nature of the dietary fat, in addition to low tocopherol intake, might help to account for the occurrence of muscular dystrophy in sucking beef calves in the north of Scotland was not supported by fatty acid analyses of milk and blood serum of cows or calves. On the contrary, rations of straw and turnips, known to be deficient in tocopherol, produced milk fat which was less unsaturated than that produced by silage rations, which do not normally cause dystrophy in the offspring. A similar trend was observed for the unsaturated fatty acid content of the blood serum of the calves.

It is concluded that the tocopherol content of the milk fat [given in table 1 as mg. per g. instead of μg. per g.] is more important than the presence of unsaturated fats in accounting for the occurrence of dystrophy.—T. R. Preston.

5379

CLARKE, E. A. and FILMER, D. B. **Hogget rearing.** *N.Z. J. Agric.*, 1956, **92,** 115–120. [Dept. Agric. Ruakura Animal Res. Stat.]

An investigation into a wasting disease of hoggets which occurs only in the autumn is described. Loss of weight occurs also in older ewes. Trials showed that parasitism was not the cause of the unthriftiness, but did become a secondary problem which could be controlled by phenothiazine. The first sign of unthriftiness coincided with the fresh growth of pasture after the first rains of autumn and the incidence could be reduced by running the sheep on mature pasture and mature pure white clover.—J. C. Gill.

5380

CARNAGHAN, R. B. A. and MARKSON, L. M. **Studies on encephalomalacia in poultry. 1. The incidence in England and Wales.** *Brit. Vet. J.*, 1956, **112,** 140–144. [Minist. Agric., Fish. Food, Vet. Lab., New Haw, Weybridge. Surrey.]

The incidence of encephalomalacia in chickens submitted to the laboratory for examination in 1953 to 1955 was 1·5 and 1·6 per cent. in the two 12-month periods. The disease always occurred between 3 and 9 weeks of age. There was no seasonal trend, and the outbreaks of the disease could not be related to feeds or feeding practice. The incidence was higher in cockerels than pullets, in the ratio 7 : 2, and highest in the heavy breeds. No relation was found between encephalomalacia and other infections.—T. D. Bell.

DEFICIENCY DISEASES

5381

RYŚ, R., GROBLEWSKA, S. and STYCZYŃSKI, H. Wstępne badania niedoboru miedzi na niektórych terenach Polski. [**Preliminary investigations on copper deficiencies occurring in certain areas in Poland.**] *Rocz. Nauk rol.* [*B*], 1955, **69,** 365–379. [Inst. Zootech., Cracow.] Russian and English summaries.

Deficiency of Cu is reported from the districts of Ostrotęka, Kolno and Pisz in Poland, predominantly on wet peat soils. Samples of pasture contained from 4·65 to 9·2 mg. Cu per kg. dry matter. Cattle were in poor condition, emaciated and often with rough coats and poor appetites. Serum Cu was from 0·37 to 1·26 mg. per litre and Hb from 6·9 to 11·5 g. per cent. The white blood picture showed high eosinophil counts. Some cows given Cu improved in general condition and in milk yield. There is need for further investigation.—D. Duncan.

5382

ALLCROFT, R. and LEWIS, G. **Relationship of copper, molybdenum and inorganic sulphate content of feeding stuffs to the occurrence of copper deficiency in sheep and cattle.** *Landbouwk. Tijdschr.*, 1956, **68,** 711–722 (with discussion 722–723). [Minist. Agric., Vet. Lab., Weybridge.] Dutch summary.

In an experiment with barren ewes on a diet of hay and mixed concentrates supplying daily 12·2 mg. Cu, 1·1 mg. Mo and 7·3 g. sulphate, supplementary Mo decreased storage of Cu in the liver. But in 6 ewes initially pregnant, more Cu was stored with Mo supplements than in 3 ewes given no extra Mo. The foetal livers contained less Cu in the group given Mo. In both experiments ewes given Mo had higher blood Cu than controls.

Ewes were stall-fed during pregnancy, and liver Cu was estimated before and at the end and in the newborn lambs. A supplement of sulphate had no effect on storage of Cu in the liver, whether the basal diet was cocksfoot straw, low in sulphate, or kale, with more Mo and more sulphate. When Cu intake was 10 mg. and Mo intake 50 mg. daily the ewes increased their liver Cu stores, and this was not prevented by addition of sulphate. On the other hand, sulphate greatly reduced liver Cu in the lambs. This was so whether the sulphate was in the form of kale or was added to the cocksfoot diet. Sulphate also reduced storage of Mo in the foetal liver.

Analyses of pasture showed no difference in Cu, Mo or sulphate between farms where there was swayback and those where it was unknown.

Low liver Cu values were produced in beef cattle in stalls and at pasture when Mo was given, but the stalled animals, unlike those at pasture, showed no clinical sign of Cu deficiency even after 18 months. Cattle with initially low liver Cu scoured when put on to pasture topdressed with Mo, but cattle with normal liver Cu did not. In stall-fed cattle large doses of Mo could cause scouring and loss of condition before the liver Cu had fallen below 40 p.p.m. on a dry basis. Thus "teart" scouring is not absolutely dependent on low Cu reserves.

Cows being treated with aluminium sulphate against fluorosis, on a farm where the Cu and sulphate contents of the grass were high, did not show an effect of the extra sulphate on liver Cu or on the liver Cu stores of their newborn calves.

5383

ENSOR, C. R. **A preliminary classification of the soils of Northland according to their copper-cobalt status.** *N.Z. Vet. J.*, 1956, **4,** 8–10. [Dept. Agric., Whangarei.]

The Pinaki soils, derived from windblown sand on the west coast, and the Maungarei soils, of volcanic origin, are probably inherently deficient in Cu. Marua soils, geologically the oldest in Northland, are probably inherently deficient in Co, though in places intrusions of volcanic rock or

limestone may correct the deficiency. Clinical deficiencies of Co and Cu appear in animals on podsolised yellow earths. Cu deficiency is often associated with acidity in volcanic rock and sometimes with dolerites and andesites, but not with basalts. Basalts, dolerites and andesites are more likely to be deficient in Co. All peats should be suspected of Cu deficiency. Marginal Cu contents in the liver of animals on some limestones may be related to the high Mo : Cu ratio in the soils.

It is suggested that all strongly podsolised soils in Northland should be topdressed at least annually with both Co and Cu. More than 5000 acres of land being developed in 1955 is classified as borderline to low in one or both elements, and animal health and production should be investigated with this in mind.—D. Duncan.

LUECKE, R. W., HOEFER, J. A., BRAMMELL, W. S. and THORP, F. (Jr.) **Mineral interrelationships in parakeratosis of swine.** *J. Animal Sci.*, 1956, **15,** 347–351. [Dept. Agric. Chem., Michigan State Univ., East Lansing.]

A group of 10 pigs, 6 weeks old, getting a ration high in Ca, 1·50 per cent., and P, 0·80 per cent., and containing 31 p.p.m. Zn all developed parakeratosis in an experiment lasting 8 weeks. Growth and efficiency of feed utilisation were poor. In a similar group of pigs a supplement of 20 p.p.m. Zn prevented the parakeratosis in all but one pig, and growth and efficiency were improved. When 20 p.p.m. Zn were given to the pigs in the first group appetite immediately improved, the skin trouble cleared up in 3 to 6 weeks, and during 6 weeks growth and efficiency were good.

A third group of similar pigs got a ration still high in Ca and P, but containing less than that of the first 2 groups. It contained 0·98 per cent. Ca, 0·70 per cent. P and 29 p.p.m. Zn. Growth and efficiency were almost as good as in pigs in the second group. Three pigs developed mild parakeratosis. A further supplement of 20 p.p.m. Zn produced excellent gains and efficiency and the parakeratosis was prevented.

The Zn content of common feedingstuffs was estimated, showing that meat-and-bone scraps and bonemeal contain more than feeds of vegetable origin. This is discussed in relation to present tendencies to reduce the amount of animal protein used.—T. D. Bell.

DISEASES OF METABOLISM

5390

SEEKLES, L. and BOOGAERDT, J. Uitkomsten van een voortgezette voederproef met magnesiumoxyde-houdende koekjes als voorbehoedend middel tegen kopziekte. [**Results of a continued feeding experiment with cake containing magnesium oxide as preventive of grass tetany.**] *Tijdschr. Diergeneesk.*, 1956, **81,** 281–296. [Lab. Med. Vet. Chem., Rijksuniv., Utrecht.] English, French and German summaries.

In continuation of earlier experiments (Title 3797, Vol. 23) a test was made in the spring of 1954 on farms in Utrecht province liable to have grass tetany, in which 976 milking cows were given daily for 4 or 5 weeks 50 g. technical magnesium oxide (about 90 per cent. MgO) in 2 portions in cake. Grass tetany occurred in 0·41 per cent. In 1426 untreated cows, 1·21 per cent. had grass tetany. The difference is moderately significant ($P = 0·032$).

In the spring of 1955, the same preparation was given to 12,700 milk cows and reports were returned for 10,000 on 569 widely scattered farms, all liable to show grass tetany ; also, in the Gouda district, Mg cake was given on 99 farms and records were kept for 54 farms without treatment.

Of the 10,000 cows, 2024 refused the cake and of them 59, or 3·00 per cent., developed tetany ; of the 7976 that took the cake, only 1·10 per cent. had tetany. In the Gouda area, of 1573 cows given cake, 0·89 per cent. had tetany ; of the

untreated controls, 4·25 per cent. All the differences between treated and untreated groups were highly significant.

Practical difficulties, of which one is the unpalatability of the magnesium oxide, are discussed. The reduction of tetany and consequent increase of production makes the treatment extremely profitable economically. Instructions for farmers are given.—I. Leitch.

MARSHAK, R. R. **Studies on parturient paresis in dairy cows with particular reference to udder insufflation.** *J. Amer. Vet. Med. Assoc.*, 1956, **128,** 423–431. [Springfield, Vt.]

The blood picture of cows before and after udder insufflation for parturient paresis was studied, and at the same time changes in the composition of colostrum. Serum Ca and P, which had fallen below physiological levels, increased after insufflation, and there was a corresponding fall in the colostrum values. There was a rise in serum alkaline phosphatase, but no corresponding fall in colostrum value. Serum and colostrum values for N.P.N., total protein, Mg and ketone bodies were not significantly affected by insufflation, and there was no qualitative change in the protein indicated in electrophoretic studies. The action of udder insufflation in curing parturient paresis, and its value, particularly in cows which have relapsed after treatment with Ca, are discussed, and wider use of the method is advocated.—T. D. Bell.

5392

ROBERTSON, A., MARR, A. and MOODIE, E. W. **Milk fever.** *Vet. Rec.*, 1956, **68,** 173–180 (with discussion 180–181 ; 182). [Royal (Dick) Sch. Vet. Studies, Univ. Edinburgh.]

Investigations are reported which show that milk fever is an exaggeration of a normal physiological condition : in normal cows at parturition there is a fall in serum Ca and plasma inorganic P and a rise in serum Mg. The changes become more pronounced in successive lactations. Pre-partum milking advanced the fall in Ca and P and the rise in Mg. Removal of the udder had little effect on plasma inorganic P changes, but to a large extent prevented the changes in Ca and Mg due to parturition and the onset of lactation.

The nature of milk fever and the treatments used are discussed. The type has changed and severity of the disease is less than 20 or 30 years ago.—T. D. Bell.

5393

REBER, E. F., BAIN, L. R., HATCH, R. D., SCHOETTLE, C. E. and SAMPSON, J. **The use of 11-ketoprogesterone in the treatment of hypoglycemia and ketonemia in the ruminant.** *Vet. Med.*, 1956, **51,** 290–292. [Dept. Vet. Physiol. Pharmacol., Coll. Vet. Med., Urbana, Ill.]

A cow with mild ketosis recovered within 24 hr. after a single treatment with 4 g. 11-ketoprogesterone, but a more severe case required 2 treatments of 2 g. with a 2-day interval, and recovered slowly within 72 hr. of the first treatment. Three cows did not respond to the hormone, but treatment with glucose was effective.

In 2 pregnant ewes hypoglycaemia and ketonaemia were induced by starvation. Response to 500 or 750 mg. 11-ketoprogesterone was variable in 1 ewe. The other doses of 1 and 2 g. reduced blood ketones slightly and improved blood sugar levels, but glucose treatment was much more effective. The cases are all described in detail.

T. D. Bell.

5394

BLOOD, D. C. **Field aspects of acetonaemia of dairy cows.** *Austral. Vet. J.*, 1956, **32,** 31–39 (with discussion 39 – 41). [Univ. Sydney.]

The 135 cases of acetonaemia observed were classified as digestive, nervous and milk fever types ; 75 per cent. were digestive type, 9·5 per cent. digestive with nervous signs, 13 per cent. nervous type and only 2·5 per cent. milk fever type. The signs of the digestive and nervous types are described : the milk fever type was regarded as acetonaemia associated with another disorder, to which it was probably secondary.

Accurate histories could not be obtained, but it seemed plain that poor nutrition could be inculpated. The disorder was more frequent after the third lactation, and during the first month after calving.

Blood sugar values were low and blood ketone bodies high in both digestive and nervous types of acetonaemia. There was no difference between types. There was a tendency for the values to be less extreme in cases not seen for more than 4 days after signs were first noticed by the farmer, but no definite conclusions could be drawn from this.

Treatment was with glucose by vein, glycerine by mouth, or both, and these methods gave the highest proportion of recoveries. Treatment with cortisone and adrenocorticotropic hormone was of doubtful value.

Other cases which differ from normal, and urine tests for the diagnosis of acetonaemia, are discussed.—T. D. Bell.

MCCLYMONT, G. L. and SETCHELL, B. P. **Ovine pregnancy toxaemia. 3. Further evidence of the correlation of depth of hypoglycaemia and induction of symptoms.** *Austral. Vet. J.*, 1956, **32,** 22–25. [Nutrit. Res. Lab., Vet. Res. Stat., Glenfield, N.S.W.]

For previous parts see Absts. 5982, Vol. 25; 2621, Vol. 26.

3. Sixty Merino ewes in advanced pregnancy were given ¾ lb. wheaten chaff per head daily and were bled daily before feeding. Analyses of the blood showed that in 16 ewes which developed pregnancy toxaemia the mean blood glucose value, 17·8 mg. per cent., at development of signs was very significantly below normal, 23·3 mg. per cent. Blood ketone levels of affected and normal animals did not differ significantly. In a second trial 9 of 20 fasted pregnant Corriedale ewes developed pregnancy toxaemia. Again blood glucose levels of affected animals were significantly below normal. Four of the 9 recovered spontaneously and recovery was accompanied in all 4 by a rise in blood glucose. The data support the identification of pregnancy toxaemia as a hypoglycaemic encephalopathy.

POISONS OCCURRING IN FOOD

5399
CLEGG, F. G. **An outbreak of copper poisoning in sheep.** *Vet. Rec.*, 1956, **68,** 332–333. [Vet. Invest. Centre, Sutton Bonington.]

Seven pedigree rams, in good condition, of a flock of 15 died showing signs of copper poisoning. The post-mortem findings confirming the diagnosis are described. The rams were grazing on a ryegrass and clover mixture containing sainfoin, and were given 2 to 3 lb. daily of a meal consisting of oats, peas, locust beans and linseed cake. They had been given a mineral supplement containing 1300 p.p.m. Cu, about 5 g. per week, for the past year, and had been drenched with a worm medicine of nicotine and Cu sulphate 10 days before the first death. No further deaths occurred after the mineral supplement was withdrawn. The danger of Cu medication in conjunction with long-term Cu mineral supplements is discussed.

NATIONAL RESEARCH COUNCIL, U.S.A. **The fluorosis problem in livestock production. A report of the Committee on Animal Nutrition.** Publication No. 381, September 1955, pp. v + 17.

Possible sources of F which may give rise to fluorosis in livestock are mineral and concentrate supplements, water supplies, pasture or forage, contaminated either by dust and splashing from the soil or by atmospheric pollution from industrial sources. The toxicity of F depends on the amount ingested, the time over which it is taken and the availability of the form in which it is present, and the development of fluorosis may be affected by physiological stress. The signs of fluorosis are described, and the care necessary for correct diagnosis is emphasised. In this respect F content of bones and teeth is important, and normal values are reported, which show that in older animals higher values than in younger are usual. Some protection against F toxicity is given by the use of pasture, ingestion of soluble aluminium salts, increased intake of Ca and adequate feeding. The value of vitamin and Mg supplements is discussed. Tolerance to F varies with the species, least tolerant being cattle, followed by sheep, pigs, chickens and turkeys. Safe levels of intake are suggested.—T. D. Bell.

Fractions of the ether-soluble portion of a commercial protein concentrate showed the presence of tetra-, penta- and hexachloronaphthalenes, which had a hyperkeratogenic effect on calves when given orally in small amounts.—T. D. Bell.

5403
BAXTER, J. T. **Suspected fodder-beet poisoning in pigs.** *Vet. Rec.*, 1956, **68,** 236–237. [Div. Vet. Res., The Farm, Stormont, Belfast.]

Pigs weighing initially 77 lb. were given 3·6 lb. meal per head daily and fodder beet to appetite. They ate 6·8 lb. per head daily of the roots and by the end of 1 month weighed 120 lb. The meal

was then changed from the original, with 15 per cent. animal protein, to one with 10 per cent. vegetable protein, and 4·14 lb. per head were given, with fodder beet to appetite. The variety of beet was also changed at the same time as the meal, from Red Otofte X to Pajbjerg Rex 10. Both varieties had been badly stored, and had a lot of green sprouts and adhering soil. Three weeks after the change of feeding, when they were eating 12 lb. beet daily, the pigs developed diarrhoea and became nervous. Body temperatures were normal but there was some coughing. The pigs improved within 10 days when the Red variety of beet was used again and consumption was limited to 10 lb. per head daily. Any subsequent increases in the allowance of beet brought on the diarrhoea again. The possible reasons for the toxicity of the beet, the presence of green sprouts or soil, or the too sudden change in diet, are discussed.—T. D. Bell.

JENSEN, R., DEEM, A. W. and KNAUS, D. **Fescue lameness in cattle. 1. Experimental production of the disease.**

MAAG, D. D. and TOBISKA, J. W. **2. Ergot alkaloids in tall fescue grass.** *Amer. J. Vet. Res.*, 1956, **17,** 196–201; 202–204. [Sch. Vet. Med., Fort Collins, Colo.]

1. Lameness due to dry gangrene was produced within 50 to 70 days in 5 out of 7 cattle grazing on tall fescue pasture in the autumn. Similar lameness was produced in 4 cattle stall-fed exclusively on tall fescue hay; similar animals given mountain grass hay were not affected. The lesions commonly affected one or both hind feet, occasionally the fore feet or the tip of the tail. The lesions are described, with photographs.

2. Samples of the grass from which the hay for the stall-feeding experiments was obtained were examined. No ergot was seen by eye on either the fescue or the mountain hay. On chemical and photospectrometric investigation alkaloids similar to those found in ergot were found in the fescue, but not in the mountain hay. A qualitative test showed that no selenium was present in any of the samples. The possibility that some form of ergot may develop on unusual parts of the grass, or that the plant may develop the toxic alkaloids, is discussed.—T. D. Bell.

5416

GREENE, E. C. **Anatomy of the rat.** Hafner Publishing Co., New York : London, 1955, pp. xi + 370. Price 180s.

This work, now a classic, was first published in 1935 by the American Philosophical Society (see Abst. 4761, Vol. 5), and has been reprinted by the Hafner Publishing Company. It is a tribute to the author's painstaking and thorough work that an unchanged reprint has been demanded after 20 years. Even greater numbers of research workers today depend upon the rat's co-operation, and this reprint will be welcomed by all of them who have access to libraries wealthy enough to afford it. The new version is on heavy, glossy paper and more handsomely bound than its predecessor, but unfortunately the photographs have suffered in the process of reproduction ; luckily they form only a small part of the illustrations, and the beautiful drawings are as good as ever.

D. Duncan.

MCILWAIN, H. **Biochemistry and the central nervous system.** J. and A. Churchill, Ltd., 104 Gloucester Place, London, W.1, 1955, pp. vii + 272. Price 40s.

In this book Professor McIlwain presents an account of the present state of knowledge of chemical change in the central nervous system. The main topics considered are the chemical composition of brain, its metabolism *in situ*, the metabolism of isolated cerebral tissues, the metabolism of carbohydrate in brain, amino acids and cerebral activities, vitamins and the central nervous system and cerebral lipids. Other chapters deal with cytochemical and histochemical aspects, changes in the biochemistry of brain during development, the action of acetylcholine, sympathin and related substances and of depressants and excitants, and the speed of chemical change in the brain. The matter is well documented, the comments authoritative and critical. At a time when the central nervous system is attracting much attention and is the subject of many publications this summary is particularly welcome and will be of value to students, teachers and research workers alike.

LAWRENCE, J. H. and TOBIAS, C. A. (Eds.) **Advances in biological and medical physics. Volume 4.** Academic Press, Inc., New York, 1956, pp. x + 356. Price 70s. 6d.

The latest volume in this series again deals with a wide variety of topics. The first article, by D. Harker, deals with the application of X-ray diffraction to crystalline proteins and the second, by G. Gamow, A. Rich and M. Yčas, with the problem of information transfer from nucleic acids to proteins. This stimulating article, in the words of the authors, " summarises recent efforts to find the formal mechanism by which hereditary chemical information presumably stored in long polynucleotide chains is transferred to corresponding polypeptide chains which form the cellular proteins ". D. Mazia discusses the background necessary for a biochemical and biophysical approach to the problem of cell division, and T. H. Wood the lethal effects of high and low temperatures on unicellular organisms. N. K. Freeman contributes

a useful article on infrared spectrometry and its application to biological chemistry, and R. L. Huff and O. J. Judd give a short account of the present state of knowledge of the kinetics of iron metabolism. W. E. Siri considers the application of modern methods to the estimation of the gross composition of the body with special reference to the measurement of body water and fat, and the final article by H. B. Jones is concerned with the interplay of disease and physiological function in the ageing process. Several of the articles illustrate the increasing application of a mathematical approach to biological problems, and the volume as a whole illustrates again the progress which is being made in the treatment of complex systems by mathematical and physico-chemical techniques.

MILLER, C. D., BAZORE, K. and BARTOW, M. **Fruits of Hawaii : description, nutritive value and use.** University of Hawaii Press, Honolulu, 1955, pp. ix + 197. Price $2.75.

The 31 fruits ranging from avocado to water melon include fruits well known outside as well as inside Hawaii, such as banana, coconut, fig, lemon, and lesser known fruits, such as carambola, ketambilla, poha and roselle. For each fruit there are notes on description, history, nutritive value, supply and use with some selected recipes. Appendixes give methods of preserving Hawaiian fruits by freezing, canning, bottling and making jelly, and quantitative data on vitamin and energy values of the fruits.—F. C. Aitken.

5420

BURTON, A. C. and EDHOLM, O. G. **Man in a cold environment. Physiological and pathological effects of exposure to low temperatures. (Monogr. Physiol. Soc. No. 2.)** Edward Arnold (Publ.), Ltd., London, 1955, pp. xiv + 273. Price 30s. net.

This book has been written, its authors say, " in the conviction that it is worth sacrificing some broadness of view to secure consistency and simplicity of presentation ", and let no one disbelieve that statement because of the abrupt plunge into the subject with a discussion of whether the existence and proliferation of life is in defiance of the second law of thermodynamics. The first chapter, on homoiothermy and history, is a pleasant mixture of fact and philosophy ranging from the distribution of human populations on the earth's surface to how often socks ought to be changed. Thereafter the pattern is more that of a textbook, but never a dull textbook. Almost every passage of solid information is enlivened by a comment or illustration which must hold the interest of scientists and the man in the street and his wife as well. If the book were read by a great many people there might be much more rational use of heat and of clothing.

A parallel book on a hot environment would be equally good for a part of the world's population and equally likely to dispel many illusions and misconceptions. What, in effect, is the equivalent in a hot climate of the summary to this book : " Many are cold but few are frozen " ?

I. Leitch.

5421

TANNER, J. M. **Growth at adolescence.** Blackwell Scientific Publications, Oxford, 1955, pp. xii + 212. Price 32s. 6d.

In the preface to this book Tanner lists those at whom it is directed, starting with medical students, and selecting as a particular target physicians concerned with children and adolescents. The reader finds himself at the end of the book far sooner than its 165 pages of text would lead him to expect, owing partly to the large number of clear diagrams, and partly to the facile presentation For this reason it is perhaps specially suitable for medical students in a world of textbooks as " inveterately convolved " as Wordsworth's yew trees.

In its short length it provides a really satisfactory introduction to many aspects of adolescence. The chapters on developmental age, the endocrinology of adolescence, changes in mentality, and the adolescent spurt in animals are particularly well presented and stimulating.

Tanner comments on the relative merits of longitudinal and cross-section surveys, but he omits one advantage of the latter, the comparative ease with which they enable secular changes to be determined. There are some points where the summary of findings is too condensed, a consequence, perhaps, of the scope of the book. On p. 91, for instance, where secular change in growth of children are dealt with, Roberts is quoted as commenting on the increase in weight of factory children between 1833 and 1876. This is taken by Tanner to imply a secular change, without consideration of the influx of country people to the towns over that period.

Again, in Fig. 3, p. 7, the first figure gives what is probably a greatly exaggerated impression of the effect of a cross-sectional survey as, in such a survey, the weighting of the extreme values would be very much less than the figure suggests.

On p. 92 the difference between children 50 years ago and today is stated to be due in part to the " ultimately reached adult size being greater ". In fact, unanimity on this phenomenon has not been reached in the literature, but even allowing for its existence it is debatable which is cause and which effect.

In passing, it may be noted that on line 3, p. 161 "adult" should presumably read "erect" or "standing", and the interesting chapter on technique has for right-hand page heading "The adolescent spurt in animals".

All in all, a worth-while production, with, for any who may disagree with some of its conclusions, what must be one of the most useful bibliographies on the topic.—A. W. Boyne.

5422

ELLIS, R. **A dictionary of dietetics.** Philosophical Library, Inc., 15 East 40th St., New York 16, 1956, pp. 152. Price $6.00.

According to the preface "this book has significance for the layman as well as the dentist, doctor, medical student, student nurse, dietitian, nutritionist and home economics major". In attempting to cater for such diverse tastes the author is likely to satisfy none. The length of definition frequently appears to be in inverse proportion to the complexity of the term; for instance, custard requires 15 lines and cyanocobalamin is dismissed in 2½ lines. Under each letter of the alphabet there is a quick change from the sublime to the ridiculous or vice versa: from polyuria to popcorn, tomato catsup to triphosphopyridine nucleotide, Waldorf salad to Winkelstein intragastric drip. The little bits of dietetic information given in the book probably would be found more readily in a textbook. The artificial arrangement is possibly responsible for such inconsistencies as the statement on p. 76 under Geriatrics: Calcium Requirement: that "the dietary calcium requirements of older people are higher than those for young adults" and the information in the Table of Recommended Daily Dietary Allowances, Food and Nutrition Board, National Research Council on p. 51 that the allowance of calcium for adults is 0·8 g. whether they be 25, 45 or 65 years of age.

5423

HOBSON, W. and PEMBERTON, J. (with BRANSBY, E. R., DROLLER, H., ROSEMAN, C. and WOODHOUSE, D. L.) **The health of the elderly at home. A medical, social and dietary study of elderly people living at home in Sheffield.** Butterworth and Co. (Publishers), Ltd., London, 1955, pp. xvi + 238. Price 30s.

At the present time, about one in eight of the population of the United Kingdom is of pensionable age and it is estimated that the proportion will be one in five in 30 years' time. It is obviously becoming a matter of some importance to know more about the incidence of disease and disability in this group. Most of our knowledge of the subject is derived from studies of old people in hospital, yet it is estimated that, in Sheffield, for instance, only about 2 per cent. of persons of pensionable age are in hospital at a given time.

The present study was undertaken to describe the state of health and the diets of 476 elderly people living at home in Sheffield, to examine the relationships between health and age, sex, marital state, social class and diet, and to collect information on normal physiological standards in the elderly. The incidence in this sample of disorders common in the elderly is examined and discussed and an attempt has been made to assess quantitatively the amount of disability caused by these disorders.

Of special interest are the results of a diet study in which 303 of the subjects weighed or measured and recorded foods eaten during one week. The diet study showed that a substantial proportion of the subjects, especially of the women, were eating less food than required to supply the calories and nutrients recommended by the British Medical Association for adults with sedentary work and little travelling. The mean daily intakes of those medically graded as fit were higher than for the sample as a whole; which was cause and which effect was not clear, but it is suggested that the intakes of the fit group and the intakes of a small group in residential homes might provide a working basis for estimating the nutrient requirements of the elderly.

The results of clinical examinations are presented in detail.

The collection of sociological data was mainly incidental to the medical study but serves to round off a very comprehensive investigation.

The need for further studies of the elderly is stressed and it is suggested that follow-up studies —from middle age to the grave—would be a fruitful method of studying the ageing process.

Some of the material presented in this book has been published in medical and scientific periodicals (see Absts. 4841, Vol. 23; 2081, Vol. 24; 3554, Vol. 26).—F. C. Aitken.

5424

SHAW, J. H. (Ed.) **Fluoridation as a public health measure.** American Association for the Advancement of Science, 1515 Massachusetts Ave., N.W., Washington 5, D.C., 1954, pp. v + 232. Price 40s.

The American Association for the Advancement of Science has, since its annual meeting in 1940, shown a particular interest in the problems of fluorine metabolism and the effects of fluoride in the prevention of caries. In this, the third and latest of its monographs, there are 11 articles. The first 4 are review articles and deal with the benefits of ingesting fluorides, the state of knowledge of fluoride poisoning and chronic fluorosis, metabolism of inorganic fluorides and the public

health aspects of fluoridation of water. The next two articles are concerned with particular experiments, the first with work in Texas and the second with the long-term work at Newburgh and Kingston in the lower Hudson Valley. There follows a review of the more fundamental work done on the action of fluorine on the outer surface of erupted and erupting teeth, and after it a review of the amount of fluorine in American diets. That amount is thought to be small and there is little information on supplementation except by fluoridation of drinking water. The last three reviews are concerned with engineering aspects of the equipment, some aspects of the origin and state of fluorine in natural waters and chemical methods for its estimation.

This compendium of information on a subject round which discussion still rages is a guide which ought to be studied by all who may have the urge to express opinions and more especially by any who are disputatious rather than scientific in their approach.—D. Harvey.

5425

MURRAY, I. **Good health with diabetes. A patient's handbook.** E. and S. Livingstone, Ltd., Edinburgh : London, 1956, 3rd ed., pp. 51. Price 2s. 6d.

This handbook instructs the diabetic patient how to control his carbohydrate intake, how to control his energy intake if a reduction in weight is desirable, and how to adapt his diet in time of illness. It tells him how to inject insulin, how to test his urine for sugar and how to deal with emergencies such as insulin reaction and diabetic coma.

It is by no means certain that the patient who uses the handbook as guide in matters of diet will achieve positive health. Although more than half of the book is devoted to diet and one chapter purports to deal with the purpose and nature of food it is noteworthy that no indication is given that foods contain anything more than carbohydrates, protein and fat, that certain minerals and vitamins are essential for health, and that diets should be chosen to give an adequate supply of such nutrients. The specimen menus for 1 week appear to supply not more than ½ pint milk daily, so that such diets would scarcely be adequate in calcium for juvenile diabetics.

It is regrettable that an opportunity has been lost to instruct diabetics how to achieve positive health through a nutritionally adequate diet at the same time as they achieve control of their diabetic condition.—F. C. Aitken.

5426

WENGER, R. Leitfaden der Diätetik für Ärzte und Diätassistentinnen. [**Manual of dietetics for doctors and dietitians.**] Springer-Verlag, Vienna, 1955, pp. xi + 165. Price 16s.

The author is the head of the dietitians' school in the First University Medical Clinic in Vienna. He has written an eminently practical book in a somewhat chatty style, rich in exclamation marks. The chapter on physiology is reduced to a bare outline, free of alarming scientific jargon. The rest of the book deals with the dietetic principles to be applied in each of a long series of disorders. The importance of considering the individual needs and tastes of the patient is emphasised more than once, and the point is made in the foreword that in a long illness the meals may be the main interest in the patient's day-to-day life. The diets are almost all based on the Austrian cuisine and the British dietitian would find it necessary to make some adjustments for differences in tastes and availability of foods. There is hardly a word about the child or infant patient.—D. Duncan.

5427

SHEEHY, E. J. **Animal nutrition.** Macmillan and Co., Ltd., London, 1955, pp. viii + 732. Price 30s.

The foreword is by Dr. John Hammond, who wisely says "If the knowledge available in the book could be widely put into practice, we could produce more milk, meat and eggs from available feeding-stuffs."

The book is concerned in the first place with Irish farming ; it is eminently readable and sound on husbandry, if not abreast of recent knowledge on the physiology of farm animals. It is well illustrated and produced and should be useful to students acquiring the elements of nutrition.

D. P. Cuthbertson.

5428

BOCETA DURAN, V. Selecciones Asociadas. (Organizacion de una mejora ganadera y de un plan nacional de control lechero-mantequero por asociaciones de criadores-seleccionadores.) [**Selection by associations. Organisation of cattle improvement and of a national scheme for control of dairy production by associations of selective breeders.**] Comisión Organizadora del Centenario de las Carreras de Ingeniero Agrónomo y Perito Agrícola y de la Escuela Central de Agricultura, Madrid, October 1956, pp. 280.

After a discussion on the general principles of selective breeding, this book deals mainly with a project for setting up a breeders' association for co-operative selection among breeders of Spanish Friesian cattle in Santander. A study has been made of types of Friesian in other countries, particularly in districts of Germany with breeders' associations.

The final section of the book gives suggestions for standards and for management, feeding and methods of selection and certification of approved cattle.—D. Duncan.

WATSON, J. A. S. and MORE, J. A. **Agriculture. The science and practice of British farming.** Oliver and Boyd, Edinburgh : London. 10th ed., 1956, pp. xii + 983. Price 31s. 6d.

This latest edition has been revised with the aid of several co-opted authors, J. A. More having died before the last edition was issued.

Even in 983 pages it is impossible to give an extensive report on modern agricultural science and practice. This is especially noticeable in respect of antibiotics. The book is particularly useful as a general introduction to the subject for the student and as a reference book for the farmer. The amount of space devoted to each subject is, however, too limited to warrant its recommendation to teachers, honours students or specialists. In other words, it is an excellent book for a good foundation on which to build a more detailed knowledge of the science and practice of British farming.

The print is excellent and most of the illustrations are clear and instructive.—J. A. Crichton.

8. SYMPOSIA, PROCEEDINGS AND CONGRESS REPORTS

Les IIIes Journées de Diététique, Rome, September, 1955. **[The third session on dietetics, Rome, September 1955.]** *Presse méd.*, 1956, **64**, 35–36.

A meeting of over 200 from different European countries.

HARRIS (35), vitamins and adrenal function ; MARANON, G. (35), diet for patients with chronic adrenal insufficiency ; DEMOLE and FABRE (35), diet for patients treated with cortisone ; PARETTI (35), balancing the diet ; FRONTALI, G. (35), enrichment of children's foods ; RANDOIN, L. and CAUSERET, J. (35), desirability or otherwise of enriching foods ; LEDERER (35), addition of vitamins to foods ; GREPPI (36), diet in middle age ; ROCHA, A. (36), diet in old age ; RICHET, C. and RICHET, G. (36), syndromes due to unbalanced diet ; AUDIER and MILLIAT, A. L. (36), diet for malnourished old people with cardiac insufficiency ; RICHET, C., BOULIN, UHRY, BOUR and RICHET, G. (36), modification of diet for old people in illness ; MUGLER, A. (36), diet for subjects with high blood cholesterol.

Proceedings of the Third International Congress of Internal Medicine, Stockholm, September 1955. *Acta med. scand.*, **154**, Suppl. 312, pp. 762.

Hypertension, pathogenesis and treatment

MALMROS, H., BIÖRCK, G. and SWAHN, B. (71–78), in a short paper on hypertension, atherosclerosis and diet, briefly report some of the findings in Italy and Sweden made by Keys's team of workers ; DE LANGEN, C. D. (81–86) describes the effects of salt depletion on the peripheral circulation ; SARACOGLU, K. (143–146) contends that it is salt that is harmful, not the sodium ion alone ; STANGL, E. (215–221) discusses the relation between pantothenic acid, the adrenals and hypertension ; administration of panthenol (500 mg.) lowers the blood pressure ; RIZKALLA, Y. (255–258) claims good results, especially in older patients, from daily treatment with liver extract, glutamic acid 5 to 10 g. and vitamin B_6 50 mg.

Collagen diseases

LONG, D. A. (333–335) briefly summarises evidence suggesting that deficiency of sulphur amino acids may be connected with susceptibility to rheumatic fever ; BLIX, G. and WERNER, I. (358–361) discuss the chemistry of connective tissue ; LOHMAN, A. J. M. (419) claims good results from injections of cobalt into patients with rheumatoid arthritis and anaemia ; KELCHNER, C. H. (471–472) presents evidence favouring the use of vitamin K to mitigate the side effects of massive doses of aspirin.

Miscellaneous

GIGON, A. (481–483) suggests that diabetes is a disturbance of assimilation, not of dissimilation ; AZERAD, E., DE BRUX, J., GODECHOT, R. and GRUPPER, C. (484–493) describe histochemical studies of the skin of diabetics ; RACHMILEWITZ, M. and GROSSOWICZ, N. (540–545) found *Bact. coli* as reliable as *Euglena gracilis*, and more rapid, for estimating vitamin B_{12} in serum ; results with *Ochromonas malhamensis* were much higher ; FRAZER, A. C. (721–726) provides evidence that defective fat absorption in children with no pancreatic lipase is due to lack of emulsification of fat in the upper small intestine and discusses the implications for treatment ; ADLERSBERG, D., HELLMAN, L. and ROSENFELD, R. S. (737–741) describe isotope studies on cholesterol metabolism in normal subjects and those with high blood cholesterol ; KERPPOLA, W. (742–745) reports studies of coenzymes containing vitamin B_1, nicotinamide or riboflavin in normal and pathological subjects ; COLLDAHL, H. (756–760) discusses cozymase and nicotinic acid metabolism in patients with asthma or hepatitis.

XVIe Congrès de la Fédération des Sociétés de Gynécologie et Obstétrique de Langue française, Brussels, September 1955. **[16th Congress of the Federation of French-speaking Societies of Gynaecology and Obstetrics, Brussels, September 1955.]** *Presse méd.*, 1956, **64**, 71–74.

ROSA (72), physiology of lactation ; BOURG, R. (72), deficiency or excess of milk ; TAGNON (73), pathogenesis and treatment of *post-partum* obesity ; BERNARD, I. (73), clinical study of post-gravid obesity ; ROCHAT, R. L. and DE WERRA, G. (74), treatment of toxicosis of pregnancy.

Première Réunion scientifique de l'Association des Diabètologues de langue française, Vals, September 1955. **[First scientific reunion of French-speaking Specialists in Diabetes, Vals, September 1955.]** *Presse méd.*, 1956, **64**, 53–54.

DEROT and RATHERY (53), treatment of diabetes with cystine; DELORE, P. and BERNIER (53), diet errors of diabetics; CAMELIN, A., RETOUL, E. and RETOUL, M. (53), vascular prognosis by means of provoked hyperlipaemia; DARNAUD, A., DENARD, G., MORREAU, G., VOISIN, R. and PECH, P. (54), acidotic diabetes in old age; LEDERER, M. J. (54), improvement by weight reduction.

Colloque du C.N.R.S. sur le comportement des homeothermes vis à vis du stimulus froid, Strasbourg, October 1955. **[Colloquium on the reactions of homoiotherms to a cold stimulus, Strasbourg, October 1955.]** *Arch. Sci. physiol.*, 1955, **9**, C3–C229.

KAYSER, C. (5–21), reactions of homoiotherms to cold; BARGETON, D. (47–62), adaptation to cold; long-term effects of heat regulation (rat, mouse); CAHN, T. and HOUGET, J. (141–169), effect of feeding on heat production (rabbit); AGID, R. (171–186), mobilisation of lipids studied by analysis of tissues (rabbit).

Proceedings of the Twentieth Annual Meeting of the American Institute of Nutrition, Atlantic City, N.J., April 1956. *Federation Proc.*, 1956, **15**, Part 1, 541–579.

AFTERGOOD, L., ALFIN-SLATER, R. B. and DEUEL, H. J. (Jr.) (541), effect of cottonseed oil and lard on cholesterol metabolism (rat); ALEXANDER, J. C. and MATTSON, F. H. (541–542), acetin fats and vitamin A metabolism (rat); ALLISON, J. B., MILLER, S. A. and BRUSH, M. K. (542), estimation of nitrogen balance indexes of dietary proteins in cat; ANDERSON, J. T., TAYLOR, H. L. and KEYS, A. (542), serum cholesterol on reducing diets high and low in fat (man); ANDRUS, S. B., MANN, G. V., FILLIOS, L. C. and STARE, F. J. (542), histological changes in experimental atherosclerosis (monkey, rat); BARBORIAK, J. J. (543), pantothenic acid deficiency and hypophysectomy (rat); BIERI, J. G., BRIGGS, G. M., FOX, M. R. S., POLLARD, C. J. and ORTIZ, L. O. (544), essential fatty acid deficiency in chick; BRESSANI, R. and MERTZ, E. T. (544), protein level in relation to lysine requirement (rat); BREWER, W. D., SWANSON, P., BURRILL, L., LEICHSENRING, J., LINKSWILER, H., REYNOLDS, M. and MANGEL, M. (544), nitrogen retention in ageing women; BROMLEY, J. W. and SODERBERG, T. E. (544–545), effect of adrenalectomy on response to *iso*leucine deficiency in rats; BURR, W. W. (Jr.) and TIDWELL, H. C. (545), distribution of labelled lipid in alimentary lipaemia (rat); CALLOWAY, D. H. and KURTZ, G. W. (545), digestibility of modified fats (rat); CARPENTER, K. J. and CLEGG, K. M. (545–546), estimation of metabolisable energy of cereal products from chemical composition; CHALOUPKA, M., WILLIAMS, J. N. (Jr.) and REYNOLDS, M. S. (546), roles of nicotinic acid and tryptophan in maintaining pyridine nucleotides, nitrogen balance and growth (rat); WU CHANG, M. L. and JOHNSON, B. C. (546), metabolism of radio-active nicotinamide in chick; CRAMER, J. W., PORRATA-DORIA, E. I. and STEENBOCK, H. (547), effect of growth hormone and vitamin D on rats on a low-calcium and normal-phosphorus diet; DAY, P. L. and DINNING, J. S. (548), anaemia in vitamin-E-deficient monkeys; DELONG, D. C., HALVER, J. E. and MERTZ, E. T. (548), essential amino acids for chinook salmon; DEUEL, H. J. (Jr.), COX, R. P., ALFIN-SLATER, R. B. and ERSHOFF, B. H. (548–549), effects of anti-oxidants on hypervitaminosis A in the rat; DINNING, J. S., SIME, J. T. and DAY, P. L. (549), metabolic disposal of folic acid; EDWARDS, C. H. and OUTLAND, C. E. (549), relationships of vitamin B_{12}, methionine and choline to metabolism of B vitamins in hepatic tissues (rat); EMERSON, G. A., ESSER, B. and PAGE, A. C. (549), nutritional studies with rats subjected to thyrotoxic stress; EVANS, H. M., NELSON, M. M., BAIRD, C. D. C. and WRIGHT, H. V. (549–550), multiple congenital abnormalities resulting from pantothenic acid deficiency in the rat; FENTON, P. F. (550), dietary protein level and regulation of food intake (mouse); FERGUSON, T. M., RIGDON, R. H. and COUCH, J. R. (550), effect of vitamin E deficiency on embryo eye (turkey); FILLIOS, L. C., ANDRUS, S. B., MANN, G. V. and STARE, F. J. (550–551), experimental atherosclerosis in the rat; FINLAYSON, J. S. and BAUMANN, C. A. (551), growth responses of spaced-fed rats; FORBES, R. M., YOHE, M. and VAUGHAN, L. (551), level of protein in diet and its biological value (rat); FOX, H. M., SWANSON, P. P. and BIRDS, E. (551), role of fat in metabolism under stress conditions (rat); FRITZ, J. C., WHARTON, F. D. (Jr.), HENLEY, R. M. and SCHOENE, R. B. (551–552), preservation of vitamin A in feeds; FRYER, J. H. (552), blood glucose responses to the energy-yielding nutrients; GARVIN, J. E. (552), estimation of phosphatides and bile acids by filter paper electrophoresis; GERSHOFF, S. N. and HEGSTED, D. M. (552–553), effect of vitamin-D-deficient diets containing various Ca : P ratios (cat); GOLDSMITH, G. A., MILLER, O. N. and UNGLAUB, W. G. (553), tryptophan as a nicotinic acid precursor (man); GREENWALD, I. (553), basal metabolism of girls in the Great Lakes region; GUBLER, C. J., CARTWRIGHT, G. E. and WINTROBE, M. M. (553), haemin chromoproteins in copper-deficient and iron-deficient swine; HALL, W. K., SYDENSTRICKER, V. P. and OLIVER, R. W. (554), effects of minor growth factors and antibiotics on growth on suboptimal diet (rat); HALVER, J. E. (554), amino acid test diet for salmon; HALVER, J. E. (554), water-soluble vitamin requirements of chinook salmon; HARPER, L. and OHLSON, M. A. (554–555), dietary practices of three samples of women; HAUCK, H. M. and SUDSANEH, S. (555), dietary study in a Thai village; HAWLEY, E. E. (555), improvement in bread quality as indicated by rat feeding studies; HERTING, D. C., AMES, S. R., EMBREE, N. D. and HARRIS, P. L. (556), nutritional studies on acetylated monoglycerides (rat); HIGH, E. G., BRIGHT, H. B. and POWELL, J. R. (556), *in vitro* hydrolysis and esterification of vitamin A; HILL, C. H. and GARREN, H. W. (556), effect of choline chloride on response of chicks to a transplantable tumour; HORWITT, M. K. (556–557), nicotinic acid and tryptophan requirements of man; HOVE, E. L. and HERNDON, J. F. (557), vitamin B_6 deficiency in rabbits; HSU, J. M., CHOW, B. F., OKUDA, K. and MCCOLLUM, E. B. (557), deficiencies of certain B vitamins and absorption of vitamin B_{12} (rat); JAHNKE, J. K. and SCHUCK, C. (558), growth of rats on bread mixtures containing non-fat milk solids with and without lysine supplementation; JOHNSTON, F. A., TREDWELL, C. and DIAO, E. (559), effect of previous calcium intake on amount retained from a low calcium diet (man); JENSEN, L. S., ALLRED, J., FRY, R. and MCGINNIS, J. (558–559), effect of vitamin injections on survival of chicks with a high mortality syndrome; KELLEY, L., OHLSON, M. A. and QUACKENBUSH, G. G. (559), nutritional quality of food purchases of urban families; KRATZER, F. H. and VOHRA, P. (559–560), effect of dietary lysine on tyrosinase activity in feather pulp (turkey poult); KULWICH, R., STRUGLIA, L. and PEARSON, P. B. (560), sulphur metabolism in baby pigs; LEE, J. M., SCHNEIDER, H. A. and OLITSKY, P. K. (560), nutritional factors and acute disseminated encephalomyelitis (mouse);

LEOSCHKE, W. L. and ELVEHJEM, C. A. (560), arginine and methionine for growth and fur development of mink on purified diets ; LIGHT, A. E., SOLOMON, C. and DEBEER, E. J. (560–561), effect of nutritional supplements on production of "Myleran" cataracts in rats ; LOJKIN, M. E., BOUCHARD, B. S. and WERTZ, A. W. (561), effect of ovariectomy and sex hormones on nicotinic acid metabolism (rat) ; LUSHBOUGH, C. H., PORTER, T. and SCHWEIGERT, B. S. (561), utilisation of tryptophan from foods by the rat ; LUTZ, R. N., DERBY, M. B., EINSET, B. M., PIERCE, Z. H. and WILLIAMS, H. H. (561–562), nitrogen retention and riboflavin metabolism in human subjects with low intakes of the vitamin ; MANGAY, A. S., PEARSON, W. N. and DARBY, W. J. (562), supplementary value of millet for low-casein, raw maize diets (rat) ; MARSH, M. E., IRVINE, E. S., GREENBERG, L. D. and RINEHART, J. F. (562), toxicity of ethionine as influenced by methionine and by pregnancy (rat) ; MARUSICH, W., DE RITTER, E. and RUBIN, S. H. (562–563), haemoglobinuria induced in the vitamin-D-deficient rat by massive injections of vitamin K ; MATTSON, F. H. (563), use of pancreatic lipase for determining the structure of triglycerides ; MAYER, J., MARSHALL, N. B. and ANLIKER, J. (563), goldthioglucose obesity and regulation of food intake in mice ; MCCLENDON, J. F. and GERSHON-COHEN, J. (563–564), effect of tea on dental caries ; MERTZ, W. and SCHWARZ, K. (564), effect of vitamin E on respiratory decline in necrotic liver degeneration ; MILLER, R. F. and PRICE, N. O. (564), effect of inorganic sulphate on molybdenum toxicity ; MORRISON, A. B., DAM, R., NORRIS, L. C. and SCOTT, M. L. (564–565), effect of ash of unidentified growth factors on growth of chickens ; MURRAY, T. K. and CAMPBELL, J. A. (565), effect of aureomycin on apparent utilisation of vitamin A (rat) ; NASSET, E. S. (565), nitrogen balance on amino acids and whole egg (rat) ; NELSON, M. N., WRIGHT, H. V., BAIRD, C. D. C. and EVANS, H. M. (565–566), effect of pteroylglutamic acid deficiency on foetal development (rat) ; O'DELL, B. L., BRUEMMER, J. H. and HOGAN, A. G. (566–567), effect of vitamin B_{12} deficiency and fasting on distribution of ^{32}P in new-born rats ; NITOWSKY, H. M., GORDON, H. H. and TILDON, J. T. (566), effect of tocopherol on creatinuria of children with steatorrhoea ; ODLAND, L. M. (567), bone density relationships in adolescence ; OKEY, R. and LYMAN, M. M. (567), food intake and sex hormone effects on serum and liver cholesterol (rat) ; OKUDA, K., STEELMAN, S. and CHOW, B. F. (567), absorption of vitamin B_{12} in hyper- and hypothyroid rat ; ORTEN, A. U., GIMBEL, N. S. and SMITH, A. H. (567–568), absorption of basic amino acids from human small intestine ; PAPADOPOULOS, N. M. and ROE, J. H. (568), absorption of fructose from intestinal tract (rat) ; PEARSON, W. N., SALVADOR VALENZUELA, J. and STEMPFEL, S. J. (568–569), supplemental value of raw, lime-treated and boiled maize added to a nicotinic-acid-free, low-casein diet (rat) ; PERDUE, H. S., LAMBERT, G. F. and FROST, D. V. (569), amino acid inadequacy of blood (dog, rat) ; PETERSON, D. W., NICHOLS, C. W. (JR.), PEEK, N. F. and CHAIKOFF, I. L. (569), plasma cholesterol in human subjects consuming butter containing soya sterols ; PINAJIAN, J. J., BACON, J. A., MRAZ, F. R. and PATRICK, H. (569–570), relation of fluorine to metabolism of ^{35}-sulphur (chicken, rat) ; PORTMAN, O. W., STARE, F. J. and BRUNO, D. (570), level and type of dietary fat and experimental hypercholesteraemia in the cebus monkey ; PRUZANSKY, J. and AXELROD, A. E. (570), pantothenic acid-sparing action of ascorbic acid in antibody production (rat) ; PUDELKEWICZ, C. and RODERUCK, C. (570), ascorbic acid and requirement of guineapigs for pantothenic acid ; REID, M. E. (570–571), protein and amino acid studies with the guineapig ; RICE, E. E., WARNER, W. D., MONE, P. E. and POLING, C. E. (571), comparison of metabolic energy of foods by rat growth under conditions of energy restriction ; ROSS, M. L. and PIKE, R. L. (571), vitamin B_6 in relation to serum protein and non-protein nitrogen during pregnancy (rat) ; SAMPSON, M. M., CARPENTER, E. and WIGHT, R. (571), effect of excess vitamin A palmitate (rat) ; SCHRAER, H. and SCHRAER, R. (571–572), bone density changes in rats fed on diets of different calcium content ; SCHROEDER, L. J., HIRATZKA, T. and SMITH, A. H. (572), torula yeast and liver necrosis (rat) ; SCOTT, M. L. and NELSON, T. S. (572), vitamin E in chick nutrition ; SCRIMSHAW, N. S., TANDON, O. B. and PÉREZ, C. (572), effect of vitamin B_{12} and antibiotics on growth of Guatemalan schoolchildren ; SIME, J. T., YOUNG, D. E., DINNING, J. S. and DAY, P. L. (573), effect of vitamin E deficiency on incorporation of glycine-1-^{14}C and formate-^{14}C into protein of muscle (rabbit) ; SMITH, J. M., CHEN, S. D., DICK, E., HARE, A., MCMILLAN, M. and MCKEY, B. V. (573), urinary creatinine as a measure of endogenous nitrogen (man) ; SNYDERMAN, S. E., HOLT, L. E. (JR.), NORTON, P., FOWLER, D. I. and HASSELMEYER, E. (573), lysine requirement of normal infant ; SQUIBB, R. L., BRAHAM, J. E., ARROYAVE, G. and SCRIMSHAW, N. S. (573–574), vitamin A and carotene serum levels in depleted chicks and children in relation to vitamin A or carotene intake ; SURE, B. (574), supplementary value of vitamin B_{12} to proteins in the infant food Pablum (mixed cereal) ; SWANSON, P. P., LEICHSENRING, J., LINKSWILER, H. and FOX, H. (574), protein nutrition of elderly women ; SWENDSEID, M. E., LONG, N. J. and HALSTED, J. A. (574), effect of aureomycin on anaemia of the gastrectomised rat ; TENNENT, D. M., SIEGEL, H., KURON, G., OTT, W. H. and MUSHETT, C. W. (574–575), lipid patterns and atherogenesis in cholesterol-fed chickens ; TRAVIS, H. F., BASSETT, C. F., WARNER, R. G. and LOOSLI, J. K. (575), effect of diethylstilboestrol on growth and reproduction of mink ; VAN ITALLIE, T. B., SHULL, K. H. and MCCANN, M. B. (575), effect of fructose on glucose tolerance (man) ; VITALE, J. J., WHITE, P. L., SINISTERRA, L., HEGSTED, D. M. and ZAMCHECK, N. (575), interrelation of protein and calories during calorie restriction (rat) ; WANNER, R. L., MOOR, J. R., BRONNER, F., PEARSON, N. S. and HARRIS, R. S. (575–576), species differences in excretion of intravenously injected calcium^{45} (man, monkey, rat) ; WASSERMAN, R. H., COMAR, C. L. and NOLD, M. M. (576), influence of amino acids on absorption of radiocalcium and radiostrontium (rat) ; WEINSTOCK, I. M., GOLDRICH, A. D. and MILHORAT, A. T. (576), vitamin E deficiency and tricarboxylic acid cycle oxidation ; WHITE, P. L., QUIROZ, A., GONZALAS, L., MORALES, S., ATKINS, J., TRULSON, M. F., COLLAZOS, C. and HEGSTED, D. M. (576–577), iron administration in a tropical area ; WIESE, H. F., HANSEN, A. E., ADAM, D. J. D. and BAUGHAN, M. A. (577), effect of linoleic acid on unsaturated fatty acids of serum of infants ; WIXOM, R. L., PIPKIN, G. E. and DAY, P. L. (577), nutritive value of compounds related to glycine for the chick ; WOODRUFF, C. W. (577–578), effect of tocopherol in a patient with xanthomatous biliary cirrhosis ; YANG, C. S., STEWART, B. and OLSON, R. E. (578), effect of coenzyme A precursors on hepatic coenzyme A levels in pantothenic acid-deficient rats ; YANG, S. P. and SWANSON, P. P. (578–579), factors influencing amino acid utilisation (rat).

Proceedings of the Biochemical Society. March 1956. *Biochem. J.*, 1956, **63**, 1P–12P.

BLASCHKO, H. and HOPE, D. B. (7P), excretion of cystathionine in pyridoxine deficiency (rat); FANTES, K. H. and O'CALLAGHAN, C. H. (10P), isolation of further vitamin B_{12} analogues; PAWAN, G. L. S. (12P), total body water in obesity (man).

Proceedings of the Biochemical Society. April 1956. *Biochem. J.*, 1956, **63**, 13P–23P.

BISSET, S. K. and COOK, R. P. (13P), faecal excretion, effect of administration of mixed plant sterols (man); BARNETT, A. J. G. and BOWMAN, I. B. R. (15P–16P), reduction of nitrate in rumen.

Proceedings of the Forty-Seventh Annual Meeting of the American Society of Biological Chemists, Atlantic City, N.J., April 1956. *Federation Proc.*, 1956, **15**, Part 1, 208–392.

ALBRECHT, A. M. (210), heat-labile form of citrovorum factor in human urine; ARNICH, L. and PEDERSON, D. J. (212), diet protein and carotene utilisation; BIRNBAUM, S. M., WINITZ, M., BROOKS, R. H. and GREENSTEIN, J. P. (221), water-soluble synthetic diet for rats; BRIN, M., SHOHET, S. S. and DAVIDSON, C. S. (224), effect of vitamin B_1 deficiency on metabolism of rat erythrocytes; BRONNER, F. (224), disposition of ^{45}Ca injected intraperitoneally (suckling rat); BUCHANAN, D. L. (226), preparative chromatography of amino acids by carrier displacement; BURNS, C. H., BROWNELL, L. E. and ECKSTEIN, H. C. (228), wholesomeness of a gamma-irradiated diet fed to rats; CHOITZ, H. C. and BERG, C. P. (232–233), effect of excess methionine on iron metabolism (rat); DAVIS, R. L., DUVALL, R. C. and CHOW, B. F. (240), vitamin-B_{12}-binding capacity of serum; DEL CAMPILLO, A. and ASENJO, C. F. (240–241), bound ascorbic acid in acerola juice; DE LUCA, H. F., GRAN, F. C. and STEENBOCK, H. (241), vitamin D and citrate oxidation (rat); DOISY, E. A. (Jr.), DANIELS, M. and ZIMMERMAN, M. A. (243–244), diet and conjugation of bile acids (rat); DRYER, R. L., TAMMES, A. R. and ROUTH, J. I. (244–245), estimation of phosphorus, improved method; ELLENBOGEN, L., WILLIAMS, W. L., RABINER, S. F. and LICHTMAN, H. C. (248), intrinsic factor evaluation; GREENBERG, L. D. and RINEHART, J. F. (265), riboflavin deficiency in the rhesus monkey; HIGGINS, E. S., RICHERT, D. A. and WESTERFELD, W. W. (274–275), competitive role of tungsten in molybdenum nutrition (chicken, rat); JACOBS, F. A., LUPER, M. and GILBERTSON, E. V., (281), amino acid absorption from the small intestine by continuous flow perfusion *in situ* (rat); JEFFAY, H. and MOZERSKY, S. (282–283), turnover rates of serum protein of normal dogs; KRAUSE, R. F. (293), provitamin A activity of beta-carotene-free non-saponifiable material from alfalfa (rat); KUTNERIAN, K. and KUYPER, A. C. (294–295), action of fluoride on bone salts; LANE, M. D., WOLF, G. and JOHNSON, B. C. (296), function of vitamin A (rat); LONGWELL, B. B., REIF, A. E. and HANSBURY, E. (303–304), corticosteroid secretion in pantothenic acid-deficient rats; MARSH, J. B. and DRABKIN, D. L. (309), effect of diet and adrenalectomy on proteinuria in experimental nephrosis (rat); MCCAY, P. and CAPUTTO, R. (311), phosphorylation efficiency on tocopherol-deficient diet (rabbit); MCCLENDON, J. F. and GERSHON-COHEN, J. (311), fractionation of fluorine in milk; MISTRY, S. P., TSENG, K. C. and RAMARAO, P. B. (316), vitamin B_{12} deficiency and uric acid synthesis (chicken); OLSEN, N. S. and CLOUET, D. H. (323), chemical composition of cerebral tissue (dog); PEIFER, J. J. and HOLMAN, R. T. (326), dietary cholesterol and essential fatty acid deficiency (rabbit, rat); REISER, R. and DIECKERT, J. W. (336–337), intestinal absorption of unhydrolysed tripalmitin (rat); ROUSER, G., JELINEK, B. and SAMUELS, A. J. (342), amino acid metabolism in human blood cells; SANTIAGO, L. S., WALDORF, M. A., MCMILLAN, M. and PARSONS, H. T. (346), metabolism of folic acid by human subjects; SAUBERLICH, H. E. and GUROFF, G. (346), microbiological studies on aspartic acid metabolism; SOBEL, A. E., BURGER, M., SAMACHSON, J. and SLOVIK, N. (358), mechanism of calcification; SPACKMAN, D. H., STEIN, W. H. and MOORE, S. (358), automatic recording apparatus in chromatography of amino acids; SPRUTH, H. C., RIEKER, R. A. and FROST, D. V. (360), tolerance to arsanilic acid in mink; STRATES, B. and NEUMAN, W. F. (365–366), mineralisation, studies *in vitro*; TAYLOR, W. R. and LANGDON, R. G. (369), intestinal absorption of glucose in the rat; UMBERGER, E. J., CURTIS, J. M. and GASS, G. H. (373–374), effect of diet on uterine weight response of rats and mice to stilboestrol; UNGLAUB, W. G., MILLER, O. N. and GOLDSMITH, G. A. (374), saturation studies with vitamin B_{12} in human subjects; WILGRAM, G. F. and BLUMENSTEIN, J. (384–385), etiology of cardiovascular disease in choline deficiency (rat).

Proceedings of the Fortieth Annual Meeting of the American Association of Immunologists, Atlantic City, N.J., April 1956. *Federation Proc.*, 1956, **15**, Part 1, 580–624.

COHEN, S. I., PATEK, A. J. (Jr.), SCHMATOLLA, E. and BEVANS, M. (584), effects of casein or amino acid mixtures on nutritional cirrhosis (rat).

Proceedings of the Physiological Society, London. February 1956. *J. Physiol.*, 1956, **132**, 1P–19P.

HUGGETT, A. ST. G. (3P–4P), estimation of blood glucose with benzidine; SMYTH, D. H. and TAYLOR, C. B. (9P–10P), effect of temperature on the rate of transfer of water by an *in vitro* intestinal preparation (rat); BREBNER, D. F., KERSLAKE, D. M. and WADDELL, J. L. (17P), relation between sweat rate and body temperature when heat loss is small (man).

Proceedings of the Seventy-sixth Meeting of the American Physiological Society, Atlantic City, N.J., April 1956. *Federation Proc.*, 1956, **15**, Part 1, 1–207.

ANDERSON, N. G. (4), electroseparation of proteins; BACCHUS, H. and DEBONS, A. F. (6), ascorbic-dehydroascorbic system in hepatic corticosteroid metabolism; BALKE, B., WELLS, J. G. and ELLIS, J. P. (7), altitude acclimatisation and work capacity; BAUMGARDT, J. P., RAU, G. C., AUYONG, T. and EISENBRANDT, L. L. (11), effect of plant juices in diet on tissue respiration (rat); BEHNKE, A. R. (13–14), body measurements in relation to bodyweight and lean bodyweight; BURGESS, L. E., CLARK, S. S. and ROLFE, D. T. (28), effect of vitamin B_{12} and grasshopper pigment on anaemia (mouse); CARROLL, K. K. and NOBLE, R. L. (31) dietary fatty acids and cholesterol excretion (rat); CHEEK, D. B. and WEST, C. D. (34–35), total body electrolytes in rat; CORSON, S. A. and CORSON, E. O. (41), association of anaemia and hyperlipaemia with hypoproteinaemia (dog); CRAIG, J. W., MILLER, M., DRUCKER, W. R. and WOODWARD, H. (Jr.) (42), carbohydrate in diet and development of fasting

diabetes (man); DI LUZIO, N. R. (49–50), effect of choline deficiency on reticulo-endothelial system (rat); ENTENMAN, C., AYRES, N. S. and BEHNKE, A. R. (Jr.) (58–59), fasting and re-feeding, effect on composition of adipose tissue (rat); GLASS, G. B. J., EBIN, L. M., BOYD, L. J. and LAUGHTON, R. (74–75), radio-active vitamin B_{12} uptake in liver disease; GRANDE, F., ANDERSON, J. T., TAYLOR, H. L. and KEYS, A. (80–81), effect of restricted water intake on urinary excretion of nitrogen on low-calorie diet free of protein; KRINSKY, N. I., CORNWELL, D. G. and ONCLEY, J. L. (113), vitamin A, carotenoids and plasma lipoproteins; CHIUNG PUH LEE, Y., KING, J. T. and VISSCHER, M. B. (117), minerals and vitamin E in mouse "paralysis"; LIN, T. M., KARVINEN, E. and IVY, A. C. (120), absorption of dietary cholesterol (man); MADDEN, R. J., PIETROLUONGO, A. L. and TORRE, A. V. (123), estimation of acid and alkaline phosphatase in stomach (man); MAIRE, F. W. (124), diencephalon stimulation, effect on eating and drinking responses; MASORO, E. J. and ASUNCION, C. L. (126), fatty acid synthesis from carbohydrate in cold exposure (rat); MILLER, A. T. (Jr.) and CONRAD, M. C. (130), basal metabolism in old age; MINARD, D., BENZINGER, T. H. and KITZINGER, C. (131), human gradient calorimeter; MONAGLE, J. E., GRANDE, F., BUSKIRK, E., BROZEK, J., TAYLOR, H. L. and KEYS, A. (132), body temperature during work on restricted water and food intake; PANOS, T. C., KLEIN, G., WALL, R. L. and FINERTY, J. C. (141), effect of hormones on fat deficiency syndrome (rat); REINER, J. M. and REINER, B. (149–150), cobaltoproteins in liver (rat); SCHMIDT-NIELSEN, K. (164), water storage in the camel; SEMPLE, R. E. (167–168), estimation of plasma volume; TAYLOR, H. L., GRANDE, F., BUSKIRK, E., ANDERSON, J. T. and KEYS, A. (185), water exchange on restricted water intake and carbohydrate diet (man); WILLIAMS, W. L. (201), inhibition of cortisone-induced weight loss by vitamin B_{12} (mouse).

British Society of Gastroenterology. Annual Meeting, Oxford 1955. *Gastroenterologia*, 1956, **85**, 130–228.

FLOREY, H. (140–141), secretion of mucus (laboratory animals); FRAZER, A. C., SCHNEIDER, R. and SAMMONS, H. G. (146–159), cellular phase of fat absorption; CHANDLER, G. N. and BENSON, J. A. (160–168), site of fat absorption in the rat; WATKINSON, G. (201–204), relationship of chronic peptic ulcer to coronary sclerosis (man).

Société Française de Microbiologie, February 1956. *Ann. Inst. Pasteur*, 1956, **90**, 489–529.

MOUSTARDIER, G., BENTEGEAT, J. and LE NOC, P. (489–493), aerobic intestinal flora of the infant and young child (LE NOC, *Thesis, Bordeaux*, 1955); MOUSTARDIER, G., BENTEGEAT, J. and LE NOC, P. (494–495), modification by antibiotics (*Ann. Inst. Pasteur*, 1956, **91**, 10); MOUSTARDIER, G., BENTEGEAT, J. and LE NOC, P. (495–498), modification by antibiotics along with yeasts, lactic enzymes and B vitamins.

Société Française de Microbiologie, March 1956. *Ann. Inst. Pasteur*, 1956, **90**, 650–673.

LÉPINE, P., SLIZEWICZ, P., DANIEL, P. and PACCAUD, M. (654–656), satisfactory growth of HeLa cells was obtained in a medium in which amino acids were supplied by casein hydrolysate; only small amounts of fowl serum were required.

52e Congrès de la Société Française d'Ophtalmologie, May 1955. *Ann. Oculist.*, 1956, **189**, 227–243.

ALAERTS, L. (234), the normal glucose content of the aqueous humour is about half that of the blood; in diabetic patients it soon rises to 60 per cent. and after 4 or 5 years to 80 per cent. (man); D'ERMO, F. (235), electrophoresis of very small amounts of normal aqueous humour (man, rabbit).

Proceedings of the Swedish Medical Society, Section of Paediatrics and School Hygiene, October 1955. *Acta paediat.*, 1956, **45**, 311–319.

BERFENSTAM, R. and BILLE, B. (312–313) report on reasons for stopping breast feeding; D'AVIGNON, M. (313–314) describes 3 children with phenylketonuria; treatment for 2 months with a diet devoid of phenylalanine removed their characteristic odour but did not improve their grossly defective mentality; HOLMBERG, J., JACOBSSON, E. and MALMBERG, N. (314–315) describe a new milk preparation, Milkotal, containing vitamin D; the addition of vitamin D to such products, and the giving of vitamin C to breast-fed infants, are criticised in the discussion.

Proceedings of the Forty-first Annual Meeting of the American Society for Experimental Pathology, Atlantic City, N.J., April 1956. *Federation Proc.*, 1956, **15**, Part 1, 505–540.

BULL, F. E., CAMPBELL, D. C. and OWEN, C. A. (Jr.) (509–510), evaluation of intrinsic factor in pernicious anaemia; KAUNITZ, H., SLANETZ, C. A., JOHNSON, R. E., KNIGHT, H. B., SAUNDERS, D. H. and SWERN, D. (521), nutritional properties of auto-oxidised fat fractions; MOSBACH, E. H., HALPERN, E. and BRUNDER, J. (525), sterol metabolism in the rabbit; MUIRHEAD, E. E. (525–526), diet protein in production of postnephrectomy hypertension (dog); MUSHETT, C. W. and EMERSON, G. A. (526), arteriosclerosis in vitamin B_6 deficiency (monkey, dog); SLANETZ, C. A., KAUNITZ, H., JOHNSON, R. E. and GUILMAIN, J. (532), weight maintenance requirements of rats fed high protein, fat or carbohydrate diets; STAMLER, F. W. (533), eclampsia in rats produced by controlled diet; TRUEHEART, R., STUMPE, M., HASS, G. and TAYLOR, C. B. (535–536), vascular and extravascular disease produced by excess vitamin D (rabbit); WISSLER, R. W., ALLEN, R. F., MOY, R. H. and BRADFORD, W. L. (539), role of arterial and renal injury in production of atheromatous lesions in coronary arteries of the rat under various dietary conditions; TAYLOR, C. B., NELSON, L., STUMPE, M., COX, G. and TAMURA, R. (534), depression of cholesterol synthesis in liver by dietary cholesterol and recovery on cholesterol-free diet (rat).

American Society for Pharmacology and Experimental Therapeutics, Inc., September 1955, Iowa City, Iowa. *J. Pharmacol. Exp. Therap.*, 1956, **116**, 1–66.

BURNS, J. J. and MOSBACH, E. H. (10–11), effect of chloretone on conversion of glucose to ascorbic acid (rat); BUTLER, T. J. (11), effect of anti-inflammatory drugs on serum protein sulfhydryl levels in scurvy (guineapig); EVANS, R. A. (19–20), intravenous fat emulsions improve the rate of wound healing after protein depletion (rat); HALLESY, D. W. and DOULL, J. (26–27), acute and chronic toxicity for rats of orange B and orange 1 (dyes for colouring food); MANTHEI, R. W. (40–41), interaction between isoniazid and ascorbic acid (mouse);

TIMIRAS, P. S., VERNADAKIS, A. and WOODBURY, D. M. (58), effects of carbon dioxide, hypoxia and hyperoxia on free amino acid metabolism in the brain (rat).

American Association of the History of Medicine, Twenty-eighth Annual Meeting, Detroit, Mich., May 1955. *Bull. Hist. Med.*, 1956, **30**, 38–51.

GREENWALD, I. (48–49), history of goitre in Spain and among Jews.

American Economic Association 68th Annual Meeting, New York, December 1955. *Amer. Econ. Rev.*, 1956, **46**, No. 2.

GILBOY, E. W. (119–133), elasticity, consumption and economic growth; DAVIS, K. (305–318), the amazing decline of mortality in underdeveloped areas; KELLOGG, C. E. (319–326), world food and agricultural potentialities; SPENGLER, J. J. (337–351), the population problem: dimensions, potentialities, limitations.

9. FOOD AND AGRICULTURAL ORGANIZATION (AND OTHER ORGANIZATIONS) OF THE UNITED NATIONS

Monthly Bulletin of Agricultural Economics and Statistics.
Vol. 5, No. 7, July 1956, pp. 48. Price $0.50.
Vol. 5, No. 8, August 1956, pp. 52. Price $0.50.
p. 1. Problems of over-all and agricultural programming.

Yearbook of Food and Agricultural Statistics. 1955, Vol. 9, Part 2. Trade. Rome, Italy, 1956. Price $3.50.

The State of Food and Agriculture 1956. Rome, Italy, 1956, pp. viii + 143. Price $1.50.

The report begins (pp. 9–60) with a review of production for 1955–56 and a statement of outlook. Production continued to rise in North America and Oceania and in parts of the Far East. International trade in foods was maintained at about the level of earlier years but the accumulation of stocks of grain, largely in North America, has not been halted. In most countries prices have continued to move against the farmer. Consumption levels have become much more stable than in the years immediately after the war. While there is, in general, little change in the world food and agricultural situation, some progress has been reported in the attention being paid in underdeveloped countries to the nutritional needs of the population in relation to agricultural development schemes.

The remaining 2 chapters deal with specialised subjects. One (pp. 61–99) contains an analysis of the development since 1913 of world trade in the main agricultural products; the other (pp. 100–127) reviews the general trends and outlook for world fisheries with examples from selected countries of policies of governments in relation to their fishing industries. The appendix contains 12 tables.

FAO Nutrition Meetings Report Series. No. 11. Joint FAO/WHO Conference on Food Additives, Geneva, 19–22 September, 1955. Rome, Italy, July 1956, pp. 14. Price $0.30. Issued also as *World Health Organization Technical Report* Series No. 107.

The conference was attended by delegates from 12 countries and by observers from 1 country and 4 international committees. Food additives were taken to be "non-nutritive substances which are added intentionally to food, generally in small quantities, to improve its appearance, flavour, texture, or storage properties". The advantages of international action are summarised. Possible lines along which FAO and WHO might assist were the collection and dissemination of scientific and technological information. An additional recommendation was that, to begin with, investigations should be of food colours, preservatives, either anti-microbial or anti-oxidant, and of emulsifiers.

Agricultural Development Paper No. 53. Co-operative marketing for agricultural producers. Rome, Italy, December 1955, pp. ix + 80. Price $1.00.

10. DEPARTMENTAL AND OTHER REPORTS

UNITED KINGDOM

Department of Scientific and Industrial Research. Report of the Food Investigation Board with the Report of the Director of Food Investigation for the Year 1955. Pp. vi + 76.

National Institute for Research in Dairying, University of Reading. Report 1955. Pp. 152.

Copper for suckling and fattening pigs.
Antibiotics and copper sulphate as growth promoters (pig).
Mode of action of antibiotics (pig).
Utilisation of water-soluble vitamins by pigs receiving aureomycin.
Preservation of liquid skimmed milk for pig feeding.
Water requirements of pigs.
Feeding whey to pigs.
Dried skimmed milk as protein supplement for fattening pigs.
Use of sodium metabisulphite and halogenated acetic acid as additions to silage.
Effect of level of roughage on fat content of milk.
Effect of change of diet on function of reticulo-rumen (cow).
Effect of level of roughage during rearing on digestive efficiency in the adult (calf).

Oestrogens in plants.
Effect of oestrogens on yield and composition of cow's milk.
Growth hormone and milk production in the mouse.
Nutritive value of ammoniated molasses (ruminant).
Effect of plane of nutrition of in-calf heifers on growth and subsequent milk yield.
Effect of level of concentrate feeding on milk yield and composition.
Effect of copper sulphate on milk fat percentage.
Estimation of liveweight from body measurements (cow).
Nutritional significance of colostrum.
Undesirable effect of dried skimmed milk in a synthetic milk (calf).
Antibiotics for calves deprived of colostrum under conditions of high " infection ".
Endocrine control of the mammary gland.
Microflora of the alimentary tract (ruminant, pig, chicken).
Estimation of solids-not-fat in milk from fat content and density.
Hypomagnesaemia and grass tetany.
Effect of change of ration on digestion and metabolism (cow).
Role of vitamin B_{12} in utilisation of protein (rat).
Evaluation of nutritive value of protein by analysis of rat livers.
Biological assay of vitamin A.
Vitamin B_{12} and the animal-protein factor.
Vitamin synthesis in ruminant.
Vitamin B content of milk in relation to breed of cow and stage of lactation.
Vitamin D content of pasture.
Possible antivitamin D activity of carotene and vitamin A.
Antibiotics and " infection " in chickens.
Inactivated penicillin and growth of chickens.
Use of radio-active calcium in metabolic studies (rat).
Adaptation to a low level of calcium intake by the adult rat.
Effect of age and level of phosphorus intake on calcium retention (rat).
Origin of milk fat in ruminants.
Paper chromatography of long-chain fatty acids.

MAURITIUS

Annual Report of the Department of Agriculture for the Year 1954. Pp. 97.

Analysis are given of species of local and imported grasses (*Panicum*, *Setaria*, Elephant, *Cenchrus*, *Chloris*, Akaroa, cocksfoot, Kikuyu, *Paspalum*, *Phalaris* and Molasses).

NEW ZEALAND

The Dairy Research Institute (N.Z.), Twenty-seventh Annual Report for the Year 1954-55. Pp. 36.

Effect of short periods of undernutrition after calving on the establishment of lactation in cows.
Dried buttermilk for calves.
Effect on yield and quality of milk of administering oils to cows to control bloat.
Variations in carotene and vitamin A contents of butterfat from a herd during lactation.
Vitamin A and carotene metabolism in dairy cows.

UNION OF SOUTH AFRICA

National Nutrition Research Institute (South African Council for Scientific and Industrial Research), Pretoria, 1956. Pp. 14.

The Institute was established as a unit in June 1954 and was later converted into a separate Institute of the South African Council for Scientific and Industrial Research. An outline of the work in progress is given as follows :
Relationship between nutrition and foetal and child development in the Bantu.
Survey of the nutritional status and dietary pattern of the different age and racial groups.
Kwashiorkor : role of pathogenic organisms in etiology ; incidence of diarrhoea ; effect of different protein supplements ; effect of digestive enzymes ; haematology and effect of folic acid, vitamin B_{12}, iron and protein ; methylation and interaction of nicotinic acid, choline, vitamin B_{12}, folacin and vitamin B_6.
Relation between intellectual function and nutrition.
Relation between salicylic acid and certain vitamins with reference to gastric acid secretion and adrenal cortex function.
Iron metabolism in pregnant Bantu women.
Fatty infiltration and necrosis of the liver.
Effect of phytic acid on mineral absorption.
Effect of vitamins and fatty acids on blood cholesterol.
Effect of nutrition on productivity.
Iodised salt in treatment of goitre.
Composition of South African foods and use of special foods (*e.g.* fishmeal and enriched magou (fermented maizemeal gruel)).

UNITED STATES OF AMERICA

64th and 65th Annual Reports of the Agricultural Experiment Station of the Alabama Polytechnic Institute, January 1, 1953 to December 31, 1954. Pp. 77.

Vitamin E deficiency in young pigs.
Nutritive value of maize of high and low protein contents (chicken, rat).
Changes in chemical and physical properties of pastures influencing their utilisation and nutritive value.
Performance of cows on immature oat forage.
Johnson grass silage and Johnson grass hay in ration of dairy cows.
Lysine deficiency in groundnut meal ration for broilers.
Rickets in caged laying hens.

THE NETHERLANDS

Voedingsorganisatie T.N.O. Report for the year 1955. Pp. 54.

Apparatus for measuring moisture in foods (see *Food Res.*, 1955, **20**, 415–423).
Copper in oils and margarine, investigation of methods of estimation.

Vitamins : chemical estimation of *dl*-pantothenic acid ; microbiological estimation of folic acid ; estimation of vitamin K_3, and vitamin D in oils containing vitamins A and D. A method was found for preserving samples for estimation of vitamin B_1.

Amino acids : notes on estimation of amino-acids with ion exchange substances ; tryptophan by a colorimetric method, cystine and cysteine together ; glutamine with special reference to its harmful effect in coeliac disease.

Preservatives.

Anti-oxidants.

Physical constants of fats.

Microbiological (bacteriological) studies of foods.

Food technology.

Feeding experiments with animals : lactose (rat) ; intermittent supply of protein (rat) ; sterilised milk (pig) ; vitamin C deficiency (guineapig) ; vitamin A deficiency (rat) ; ration for guineapigs in which vitamin C is stable.

Studies on man : metabolism of glutamine and gliadin in coeliac disease ; fat absorption ; wheat in the diet of patients with myotony ; metabolism of unsaturated fatty acids in patients with eczema.

Studies of nutrition of the Netherlands population : skeletal age of infants ; somatometric studies of schoolchildren and recruits ; studies of diet and health of old people ; dental caries ; diet and athletics ; diet on board herring fishing boats.

Studies in tropics : composition of blood ; vitamin C content of potatoes and sweet potatoes.

Nutrition in Aruba : Reports of sections dealing with fish (30–32), grain and bread (33–40), and of subsidised investigations, with the Ran diet (mean Netherlands diet) for rats (41–44) ; estimation of B vitamins and of Na and K for tables of composition of food ; diet of fishermen (45) and of urban and rural schoolchildren ; analyses of studies made during the occupation.

AGRICULTURAL INSTITUTE ALLAHABAD
